Gallocyaninesulphonic acids; Process for the production of new —. Farbenfabriken vorm. F. Bayer and Co. Fr. Pat. 399,636, Feb. 19, 1909. Under Int. Conv., May 13, 1908.

FEW gallocyanines are obtained by condensing nitroso-derivatives of primary or secondary amines with 1:2:3-pyrogallol-5-sulphonic acid. Example: A mixture of 8.6 kilos. of nitrosodimethylaniline hydrochloride, 24 kilos. of 1:2:3-pyrogallol-5-sulphonic acid (potassium salt) and 250 kilos. of methyl alcohol is boiled under a reflux condenser for 6 hours. After cooling, the dyestuff is filtered off. On chromed wool the shade produced is redder and purer than that produced by gallocyanine. —J. C. C.

Halogenated vat dyestuffs dyeing like Indigo; Production of —. Soc. pour l'Ind. Chim. à Bale. Fifth Addition, dated April 7, 1908, to Fr. Pat. 372,627. Dec. 17, 1906.

AT dyestuffs are obtained by condensing the α -aryldes of 2:3-diketodihydro-1-thionaphthene or its derivatives with indoxyl or its substituted derivatives and halogenating the products as described in the chief patent and the previous Additions. Example 1: 15 parts of 3-oxy-1-thionaphthene are dissolved in 150 parts of alcohol, —2 parts of sodium carbonate or acetate added and an alcoholic solution of 10.7 parts of nitrosobenzene. An energetic reaction results which necessitates the use of an efficient reflux condenser. The mass is further heated on the water-bath, filtered hot, and part of the alcohol distilled off. On cooling, the anilide crystallises in orange leaflets, m. pt. 147° C. Example 2: 23.7 parts of the anilide just described are boiled with 17.5 parts of acetylindoxyl or 13.5 parts of indoxyl, 10 parts of sodium carbonate and 100—120 parts of alcohol on the water-bath for three hours. The precipitated dyestuff forms small, deep violet crystals with a coppery lustre. It yields a yellow vat from which cotton is dyed in reddish-blue shades moderately fast to washing. Example 3: 4 parts of the dyestuff just mentioned are suspended in 100—140 parts of nitrobenzene, 27 parts of bromine added and the mixture is heated on the oil-bath in about half an hour to 220°—230° C.; it is maintained at this temperature for an hour and, on cooling, the brominated dyestuff is filtered off. It forms a coppery, deep violet powder giving a brownish-yellow vat from which cotton dyed in violet-blue shades becoming redder on soaping. The dyeings, after soaping, are fast to washing, light, and lustrous.—J. C. C.

Vat dyestuffs; Process for preparing red —. Ges. f. Chem. Ind. in Basel. Ger. Pat. 212,870, Dec. 3, 1907. Addition to Ger. Pat. 205,377, Jan. 17, 1907. (See Eng. Pat. 344 of 1908; this J., 1908, 399.)

PHENANTHRENEQUINONE derivatives, containing halogen groups attached to the naphthalene nucleus, are condensed with phenylthioglycol- α -carboxylic acid or with oxy-(1)-thionaphthene. The resulting dyestuffs have greater affinity for cotton fibre than the unsubstituted dyestuffs, and are faster to light and deeper in shade than the dyestuffs obtained by halogenating the unsubstituted dyestuffs.—T. F. B.

Red dyestuff insoluble in water and specially suitable for the manufacture of lakes; New —. Act. Ges. f. Anilinfabr. Fr. Pat. 399,132, Feb. 4, 1909.

A dyestuff prepared by combining diazotised 6-nitro-3-amino-4-cresol methyl ether

with β -naphthol forms a reddish-blue paste which is converted into a red lake by admixture with an appropriate substratum such as aluminium hydroxide, blanc, etc.—J. C. C.

Also colouring matters and intermediate products; Manufacture of —. J. Y. Johnson, London. From Badische Anilin und Soda Fabrik, Ludwigshafen on Rhine, Germany. Eng. Pat. 26,478, Dec. 7, 1908.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

Silk: Hydrolysis of — by strong acids and alkalis. E. Abderhalden, F. Medigrescanu, and L. Pincussohn. *Z. physiol. Chem.*, 1909, **61**, 204—209. (See also this J., 1909, 518.)

It is an open question whether in the ultimate hydrolysis of proteins, the resulting amino-acids are secondary products, and do not represent groups originally present. The present is a quantitative study of the hydrolysis of the protein of raw silk (wastes). 100 grms. were treated with (1), concentrated hydrochloric acid; (2), 25 per cent. sulphuric acid; (3), 25 per cent. sodium hydroxide solution; and (4), a saturated solution of barium hydroxide. The main products were identical, namely tyrosine, glycocoll, and alanine, of which the yields were approximately the same in all cases. The following are the approximate yields obtained per 100 grms. of raw silk:—Glycocoll, 26 grms.; tyrosine, 7 grms.; alanine, 12 grms. The results furnish further evidence of the individual constitutional characteristics of the proteins.

—W. N. B.

Silks: Proximate composition [and constitution] of various —. III. Monoamino-acids from Shantung tussah silk. E. Abderhalden and C. Brahm. *IV. Monoamino-acids from Bengal silks.* E. Abderhalden and J. Sington. *Z. physiol. Chem.*, 1909, **61**, 256—260.

THE authors have applied the methods previously described (this J., 1909, 240, 518) to the investigation of tussah silks. The hydrolysis of a Shantung variety with strong acids yielded a residue of considerable amount, which contained 16.5 per cent. of nitrogen, and on alkaline hydrolysis, yielded alanine. This residue is under further investigation. In the hydrolysis of the silk fibroin there were obtained per 100 grms., 14.5 grms. of glycocoll, 22 grms. of alanine, and 9.7 grms. of tyrosine, with small proportions (under 2 per cent.) of serine, leucine, proline, phenylalanine, and glutamic acid, respectively.

From degummed Bengal silks, the quantitative yields of ultimate products were similar, the only difference being the relatively high yield of glycocoll. The following numbers may be noted, the figures representing yields per 100 grms. of fibroin:—Glycocoll, 30.5 grms.; tyrosine, 10.0 grms.; alanine, 20.0 grms., with small proportions of serine, leucine, phenylalanine, and proline.—W. N. B.

Cotton from Southern and Northern Nigeria. Bull. Imp. Inst., 1909, **7**, 154—159.

FOUR samples of cotton from Ibadan and two from Lafenwa, S. Nigeria, proved of satisfactory quality, and, with one exception (which was stained brown and yellow in places, but possessed good length and lustre) compared favourably with standard commercial specimens of similar varieties. Two of the samples—rough native varieties—resembled Peruvian cotton in quality, and might possibly be utilised for mixing with wool in the manufacture of "union" yarns. Of seven further samples of unginned cotton from S. Nigeria (4 from Ishan, and 1 each from Hon, Abeokuta, and Meko), only that from Hon was of satisfactory quality. A small sample of cotton from Lagos was coarse and somewhat dark in colour, but was otherwise similar to rough Peruvian cotton. Two samples of cotton from Northern Nigeria, from Shonga and Nassarawa respectively, were examined. The former was similar in appearance to a low quality of brown Egyptian cotton, but was much rougher and inferior in colour. The sample from Nassarawa contained a small amount of immature fibre, and was of rather irregular strength, being weak in places. If free from immature fibres, it would be readily saleable as a rough-stapled cotton similar to Brazilian or Peruvian cotton.—A. S.

Sisal hemp from the East Africa, Uganda, and Nyasaland Protectorates. Bull. Imp. Inst., 1909, **7**, 160—161.

SISAL hemp from the E. Africa Protectorate (I.) consisted of well-cleaned fibre, nearly white, very lustrous, of excellent quality and good strength, and about 5 ft. long; it was valued at £29 per ton (Mexican Sisal hemp at £24). The Uganda sample (II.) was white, of fair lustre, very well cleaned, of rather uneven strength, and about 4 ft. 9 ins. long; it was valued at £27—£28 per ton (Mexican Sisal hemp at £25). The Nyasaland sample (III.) was nearly white, of good lustre, well cleaned, of excellent strength, and 4 ft. to 4 ft. 6 in. long; it was about equal in value to Mexican Sisal hemp. The results of the chemical examination of the samples are given in the following table (compare this J., 1907, 757).

	I.	II.	III.
	per cent.	per cent.	per cent.
Moisture	11.1	7.9	9.2
Ash	1.0	0.7	0.5
α -Hydrolysis (loss)	11.2	9.2	8.6
β -Hydrolysis (loss)	14.1	11.3	11.1
Acid purification (loss)	2.3	0.7	0.35
Cellulose	78.2	80.3	80.9

—A. S.

Mauritius hemp and "Likanga" fibre from Nyasaland. Bull. Imp. Inst., 1909, **7**, 162—163.

FOUR samples of Mauritius hemp were examined and were valued at £20, £20 10s., £20, and £19 per ton respectively, with "good fair" Mauritius hemp at £21 to £21 10s. per ton. The sample of "Likanga" fibre consisted of white, very lustrous, fine fibre, of poor and uneven strength, and about 3 ft. long. Similar fibre of better strength would be worth £20—£25 per ton in London.

—A. S.

PATENTS.

Fibres [artificial silk]: Apparatus for making — from solutions. W. A. E. Crombie, London. Eng. Pat. 16,557, Aug. 6, 1908.

THE cellulose solution is delivered from a perforated nozzle into a vessel through which the coagulating liquid flows without intermission, the level of the liquid in the vessel being kept constant. The outlet pipe, which is immediately below the spinning nozzle gradually tapers, and bends upwards, the effect being that the rate of flow of the coagulating liquid increases and the threads are carried to the end of the pipe without coming into contact with, and being damaged by the walls. Upon leaving the pipe the threads pass to grooved rollers, or inclined planes, for further treatment.—F. M.

Artificial fibres from nitrated cotton: Production of — Soe. Anon. des Celluloses Planchon. Fr. Pat. 399,218, April 15, 1908.

THE invention is an improvement on Fr. Pat. 382,718 of 1906 (this J., 1908, 221), being intended to increase the productive capacity of the machine therein described, and to regulate the formation of a fibre of collodion issuing from a nozzle into a vessel containing a liquid by which the solution of collodion is coagulated. The apparatus consists of a number of units, each complete in itself and each containing a nozzle and a vessel to receive the fibre ejected from that nozzle. The nozzles are fed by cylindrical vessels containing collodion and fitted with pistons which are operated by compressed air. By altering the air pressure the supply of collodion to the nozzles is regulated. Each cylinder supplies one or more nozzles. The nozzle is connected to the cylinder by a flexible tube provided with a tap and also with a filter. By a mechanical device the tube moves in a conical path, the nozzle describes a circular path in a horizontal plane, and the receptacle underneath the nozzle revolves on a vertical axis in such a way that its radius corresponds to the diameter of the circle described by the nozzle. The fibre is thus deposited in circles passing

through the centre of the receptacle and touching its inside wall. The fibre solidifies under the action of the liquid in the receptacle (see Fr. Pat. 361,960 of 1905; this J., 1907, 197), and in this way is said to give a product which can be readily taken out and further manipulated without damage.—S. H. H.

Silk product and process for the treatment of silk. J. Knup, Paterson, N.J., Assignor to The Hellwig Silk Dyeing Co. U.S. Pat. 931,433, Aug. 17, 1909.

In order to obtain a weighted silk of a uniform blue-black colour, the silk is weighted in successive baths containing tin tetrachloride, sodium phosphate and a silicate, then subjected to a bath of pyrolignite of iron, next to treatment with gambier, logwood and fustic, and finally to a bath containing logwood and soap.—J. C. C.

Embroideries; Production of — by local carbonisation. L. Cassella und Co., Ges.m.b.H. Fr. Pat. 399,529, April 23, 1908.

In embroidering with cotton thread upon a silk or wool ground, the removal of the silk or wool requires the use of a boiling bath of caustic alkali, whereby the shade of the dyed cotton may be injuriously affected. With silk or wool upon a cotton fabric, the cotton is removed by impregnating with sulphuric acid or a solution of aluminium chloride, and heating in a stove. Various drawbacks to this process disappear when the carbonising liquor is thickened with starch, dextrin, or glucose. The impregnation is more uniform, and by using aluminium sulphate the cellulose is not blackened on heating and the residues may be removed without leaving any stain on the embroidery.—F. M.

Stearine emulsions; Employment of — in bleaching. E. Lasbordes. Fr. Pat. 399,514, Feb. 8, 1909.

THE process consists in treating the material with a mixture of stearine ("emulsified or saponified") and hydrogen peroxide, sulphurous acid, sodium bisulphite solution, etc. The treatment is carried out at 30°–40° C. in a bath containing 5–15 per cent. of stearine and sufficient of the other ingredients to give the desired effect. Bleaching takes place rapidly, and the goods are finally rinsed and dried.—F. M.

Dyeing, mordanting or similarly treating slubbing, yarn and other fibrous material; Machine for —. J. Kershaw and J. T. Cole, Menston, Yorks. Eng. Pat. 16,329, Aug. 1, 1908.

To ensure even and regular dyeings, the material is alternately squeezed and permitted to expand as nearly as possible to its normal condition in the dye-liquor, thorough penetration of each individual fibre being thus obtained. Means are provided whereby the false bottom upon which the material is placed in the dye-vessel is slowly raised (compressing the material against the cover) and is then rapidly lowered, remaining at rest for such a period as will permit of the material expanding to the full extent before the squeezing operation is repeated.—F. M.

Dyeing; Machine for — with a circulating bath. L. Mascelli. Second Addition, dated May 5, 1908, to Fr. Pat. 380,671, Aug. 10, 1907 (this J., 1908, 20, 499).

Is the original specification, and the first addition thereto, claim was only made for the use of the machine for dyeing purposes. The present addition protects its employment for mordanting, rinsing, soaping, and similar operations.—F. M.

Dyeing fibrous materials; Apparatus for —. L. Mascelli. Second Addition, dated May 5, 1908, and Third Addition, dated Feb. 20, 1909, to Fr. Pat. 384,798, Dec. 6, 1907 (this J., 1908, 499 and 938).

(1). A SIMPLIFIED arrangement of vats and reservoirs is described, whereby the various treatments of the material may be carried out in one dye-vessel, with one reservoir. A second improvement in the dyeing of cheeses consists in mounting these upon perforated truncated cones which fit one into the other, and permit of the free circulation of the liquors through the material.

(2). The apparatus described in the First Addition to the original patent may be simplified by introducing only one intermediate heating vessel between the reservoir and the dye-vessel. The arrangement is described in detail.—F. M.

Textile materials; Apparatus for circulating, by means of a vacuum and of atmospheric pressure, the liquors employed in the treatment of —. L. Mascelli, Fr. Pat. 399,895, May 7, 1908.

THE material to be treated is placed in a closed vat, connected by pipes (with valves) with a cylindrical vessel placed at a higher level. This cylinder is also in connection with a second one in which a vacuum may be produced by means of a pump or by steam condensation. The liquors for the treatment of the material are contained in separate reservoirs, connected by pipes with the cylindrical reservoir, and are filled into this as required by diminishing the pressure in the vacuum cylinder. Under the influence of atmospheric pressure, the liquors flow through the material in the vat and may be circulated as desired.—F. M.

Two-colour effects on half-wool fibres and fabrics; Process for producing —. Farbwerke vorm. Meister, Lucius, und Brüning. Ger. Pat. 212,242, Dec. 18, 1907.

HALF-WOOL goods are treated for about half an hour, in the jigger, at about boiling temperature, with tannin and a metallic salt which forms no precipitate with tannin (e.g., zinc sulphate, sodium tungstate); the goods are squeezed, without rinsing, and then treated by the bisulphite process (see Eng. Pat. 8631 of 1907; this J., 1908, 559) with a sulphide dyestuff (which dyes the cotton) and finally with an acid dyestuff (which dyes the wool).—T. F. B.

Brown dyeings and printings; Process for producing —. Farbwerke vorm. Meister, Lucius, und Brüning. Ger. Pat. 212,793, June 7, 1907.

FAST brown dyeings or printings are obtained by combining a diazotised nitraniline, especially *p*-nitraniline, on the fibre, with a mixture of Chrysoidine or Vesuvine and a *m*-diamino compound or a substituted *m*-diamino compound, the following being specially suitable:—*m*-toluylendiamine, *m*-diaminoditolyldiamine, *m*-aminodimethylaniline, dimethyl-*m*-phenylenediamine, and dimethyl-*m*-toluylendiamine. The Chrysoidine or Vesuvine and *m*-diamino compound are preferably present in equal quantities. The shades produced are much deeper than those obtained by using twice the quantities of Chrysoidine or Vesuvine when employed alone. The process has a further advantage, that the Chrysoidine mixed with the diamino base dissolves easily and without residue in hot water, whereas alone it resinifies.—T. F. B.

Thread; Process of coating —. E. D. C. Bayne and L. A. Subers, Cleveland, Ohio. U.S. Pat. 929,651, Aug. 3, 1909.

THE process consists in opening the fibres composing the thread by heat, evaporating a volatile medium therein, and filling the interstices between the fibres with the plastic and vulcanisable coating material. A succession of thin coatings are evenly distributed on the thread in a vertical position, and each coating is dried by means of an air blast, the thread being finally shaped to a perfect cylindrical form between polished surfaces.—J. C. C.

Drying or otherwise treating textile fibres, fabrics, &c.; Apparatus for —. Tomlinson-Haas, Ltd., and J. Standeven, Manchester. Eng. Pat. 16,689, Aug. 8, 1908.

THE material is placed on superimposed, pervious trays, in an airtight casing. The trays are introduced at the top of the casing and are slowly transported to the bottom. In their passage they meet a current of hot air which is drawn through the apparatus, but this current after passing over one tray does not pass directly to the next, but is first diverted through a heating chamber. The air is

thus reheated to maintain a normal temperature, or its temperature may be gradually raised as it passes to the colder, moister material.—F. M.

Fatty acids recovered from the waste soapy waters from dye works and calico-printworks; Process for decolorising and purifying the — N. Planowsky and N. Philippoff. Ger. Pat. 212,708, Feb. 28, 1908.

SOAPY waters, obtained in dyeing and calico printing, are treated with mineral acids to recover the fatty acids in the usual manner; the mixture is then heated to 50—55° C., and filtered through a press, when the fatty acids pass through the press, freed from the dyestuffs which were present as laves. The fatty acids are now washed with hot water, completely freed from the water, and heated to 140° C. with zinc dust, or finely divided iron, or a mixture of the two; the mixture is agitated and its temperature quickly raised to 200—220° C. When the azo dyestuffs and alizarin are completely reduced, the metals are separated, and the fatty acids cooled to 100—110° C. and treated with about 40 per cent. of their weight of sulphuric acid of 65° B., to convert the reduction products into sulphonic acids, which are removed by treating with hot water, the sulfonated fatty acids being converted at the same time into hydroxy-fatty acids. The product is finally distilled with superheated steam.—T. F. B.

Cellulose solutions for making artificial threads; Process of making — P. Friedrich. Fr. Pat. 400,321, Feb. 13, 1909. Under Int. Conv., Feb. 19, 1908.

SEE Eng. Pat. 4104 of 1909; this J., 1909, 934.—T. F. B.

Printing colours containing vat dyestuffs in the form of their leuco compounds; Production of — Soc. pour l'Industrie Chimique à Bâle. Fr. Pat. 400,460, June 5, 1908.

Soap compound [for making cotton non-inflammable]. Eng. Pat. 717. See XII.

VII.—ACIDS, ALKALIS, SALTS, AND NON-METALLIC ELEMENTS.

Caro's acid. H. Arble. Z. angew. Chem., 1909, 22, 1713—1715.

THE author describes a simpler form of apparatus in which the synthesis of Caro's acid from sulphur trioxide and hydrogen peroxide (see this J., 1909, 363) can be effected. The modified apparatus is shown in the accompanying figure. The lowermost part of the cylinder, *a*, is placed in a refrigerating mixture, and a current of air, charged with sulphur trioxide, is drawn through the tube, *r*₂, and the capillary tube passing through the tap, *h*. The air leaves the apparatus through the tube, *t*, and is passed through sulphuric acid monohydrate to absorb excess of sulphur trioxide. As sulphur trioxide is gradually deposited

in *a*, the latter is moved downwards into the refrigerating mixture, the tube, *r*₂, being kept fixed and the remainder of the apparatus displaced; the joint, *i*, between *r*₂ and *b*, is composed of smooth asbestos paper held in place by rubber rings. When sufficient sulphur trioxide has been deposited in *a*, the tube, *r*₂, is withdrawn, and a reserve tube introduced. A small funnel tube, containing 100 per cent. hydrogen peroxide, and closed above and below by ceresin stoppers, is now fixed in *s*, and by removing the lower stopper and slightly raising the upper one, the requisite quantity

of the peroxide is allowed to flow into the capillary tube which projects through the tap, *h*, half-way into *a*. During this operation the cylinder, *a*, is well cooled, and *t* is connected with a drying apparatus. It is best to place the apparatus in an inclined position, so that the hydrogen peroxide first falls on to the side of *a*, and only slowly comes in contact with the sulphur trioxide. Samples of the Caro's acid produced by the interaction of the sulphur trioxide and hydrogen peroxide, can be withdrawn as required by means of the tube, *r*₂. Further experiments with the acid thus prepared confirmed the view that Caro's acid is monobasic monosulpho per-acid. (See also this J., 1909, 653).—A. S.

Acid sulphates of potassium. J. D'Ans. Z. anorg. Chem., 1909, 63, 225—229. (See this J., 1903, 1193; 1908, 854.)

A PHYSICO-CHEMICAL study of mixtures of aqueous solutions of potassium sulphate and sulphuric acid has shown that besides the compounds, K₂H(SO₄)₂ and KHSO₄, two other acid sulphates exist at 0° C., and one at 25° C. The salts are intermediate in composition between the two formulated above, but their exact formulae have not been determined.—F. SODN.

Phosphates; Quantitative determination of alkali — by direct acidimetry. E. Pozza-Escot. Bull. Assoc. Chim. Suer. et Dist., 1909, 26, 1162—1163.

A QUANTITY (e.g., 10 c.c.) of the solution of the alkali phosphate is treated with 2 drops of 0.2 per cent. solution of methyl orange and 5 drops of 1 per cent. solution of phenolphthalein, and then with dilute sulphuric acid until the methyl orange is just reddened. The solution is then rendered neutral to methyl orange by careful addition of alkali solution; at this point, the colour should be very distinctly yellow without any reddish tint. The solution, which now contains the whole of the phosphoric acid in the state of monobasic phosphate is titrated with *N*/1 or *N*/10 alkali, the end-point of the conversion of monobasic into dibasic phosphate being that at which the phenolphthalein is just reddened. One c.c. of *N*/1 alkali is equivalent to 0.071 gm. of phosphoric anhydride. The method is not applicable to phosphates other than those of the alkalis.—L. E.

Ammonium phosphate; its volumetric determination, with some notes on the availability of the lead oxide method. J. M. Wilkie. Chem. and Drugg., 1909, 75, 379—380.

THE lead oxide method for the determination of phosphoric acid gives accurate results in the analysis of ammonium phosphate, if the latter be free from non-volatile impurities, and the method be carried out as follows. The solution of the salt is evaporated with lead oxide on the water-bath, and the residue gently heated until ammonia is no longer evolved. The containing crucible is then cooled, and the inner walls washed with a few c.c. of water to carry down any phosphoric acid deposited thereon; the contents are now evaporated, and the residue ignited to constant weight. The phosphoric acid in ammonium phosphate can also be determined volumetrically by a modification of the author's method (this J., 1909, 68). The solution of the salt is boiled with a known volume of *N*/10 sodium hydroxide to expel ammonia, then a quantity of sulphuric acid equivalent to the alkali is added, and after further addition of sodium acetate and silver nitrate, the liberated acetic acid is titrated with barium hydroxide solution and phenolphthalein as previously described (*loc. cit.*). If great accuracy is not required, both the phosphoric acid and ammonia of ammonium phosphate may be determined by the following simple method. 10 c.c. of a solution of the salt (13.21 grms. in 100 c.c.) are treated with 30 c.c. of *N*/1 sodium hydroxide and concentrated to 5 c.c.; after mixing well with a few c.c. of hot water, the solution is titrated with *N*/1 sulphuric acid and methyl orange. If a c.c. of acid be used, the percentage of the theoretical quantity of phosphoric acid (H₃PO₄) is equal to 10 (30 - *x*). A further 10 c.c. of the original solution are titrated directly with *N*/1 sulphuric acid and methyl orange. If *y* c.c. of acid be used, the percentage of the theoretical quantity of ammonia (NH₃) is equal to 5(*y* + 30 - *a*).—A. S.

Solubility [of zinc sulphate and cadmium sulphate]; Influence of pressure (up to 1000 atmospheres) on —.
E. Cohen. Z. Elektrochem., 1909, 15, 600.

A DETERMINATION of the influence of pressure on the solubilities of zinc sulphate, $\text{ZnSO}_4 \cdot 7\text{H}_2\text{O}$, and cadmium sulphate, $\text{CdSO}_4 \cdot 8\frac{1}{3}\text{H}_2\text{O}$, at 25°C ., shows that increase of pressure reduces the solubility of the former salt and increases that of the latter; the results are shown in the following table, the figures representing grams of anhydrous salt in 100 grms. of water:—

Pressure (atmos.).	Solubility.	
	Zinc sulphate.	Cadmium sulphate.
1.....	57.95	76.80
250.....	57.93	77.40
500.....	57.91	78.00
750.....	57.73	78.36
1000.....	57.55	78.73

Graphite; Recent discoveries of — in British African Colonies. Bull. Imp. Inst., 1909, 7, 166—169.

OF the numerous occurrences of graphite and graphite-bearing rocks recently reported from British African colonies, those in Nyasaland and Rhodesia alone appear likely to be of commercial value. In the north-west of the Upper Shire District, Nyasaland, seven different parallel bands of graphite gneiss have been discovered, in which the graphite is interfoliated in large flakes with the other constituents of the rock. Samples proved to contain from 70.6 to 91.6 per cent. of carbon, and it is stated that if carefully cleaned, the material would probably yield flake graphite worth about £40 per ton. A sample of graphite from a deposit in the Angoniland District, Nyasaland, consisted of practically pure graphite, in the form of coarse flakes up to 2 ins. long, and resembling good Ceylon graphite. It was valued at £32 to £34 per ton, and was classed as "ordinary lump of superior quality." Steps are being taken to work the deposit. A sample of graphite from North-East Rhodesia contained 79.57 per cent. of carbon and 16.83 per cent. of ash, mostly felspathic material; it was of a lustrous black colour and possessed a coarsely crystalline structure resembling that of Ceylon graphite. A clean piece of graphite selected from the sample contained 99.33 per cent. of carbon.—A. S.

PATENTS.

Sulphuric acid; Concentration of — and apparatus therefor. J. Mackenzie, Middlesbrough. Eng. Pat. 6415, Mar. 17, 1909.

SULPHURIC acid is concentrated to about 150° Tw. in lead pans, and flows thence through a series of fused-

silica evaporating dishes, arranged in "cascade" form. By displacement of the liquid in successive dishes, the acid finally reaches the lowermost dish, from which it is discharged into a receiver. Any closed type of furnace may be used as source of heat, and the evaporating dishes are arranged in the form of steps over the furnace, a flue from the latter communicating heat to the underside of the dishes. The latter are provided with hoods, through which acid-proof pipes lead a current of air from a main through the acid, and assist the concentration of the latter by thorough agitation. The hot gases from the furnace enter the lower portion of the "cascade" concentrating chamber, and pass along underneath the evaporating dishes, then under the leaden pans, in which the first concentration of the dilute acid takes place, and thence to the chimney.—O. R.

Sulphuric acid; Process of manufacturing —. W. Hallock, New York. U.S. Pat. 930,471, Aug. 10, 1909.

SULPHUR dioxide is subjected to the influence of an ionising agent (e.g., radio-active material) in the presence of oxygen; sulphur trioxide is thereby produced.

—F. SODN.

Chemical-reaction furnace, and method of making [hydrochloric] acid. J. L. Tufts, Boston, Mass., Assignor to Merrimac Chemical Co. U.S. Pats. 930,441 and 930,442, Aug. 10, 1909.

THE furnace consists of two communicating superposed reaction chambers, each provided with ploughs, secured to a common rotatable vertical shaft, for working the material and transferring it from chamber to chamber. The material is worked at a moderate temperature in the

upper chamber, until portions become fairly solid, and these are continuously transferred to the lower chamber to be heated more strongly, the more fluid part being retained for further treatment in the upper chamber by arranging a suitable depression in the hearth. A dead gas space is provided between the hearth of the upper chamber and the flue beneath by an apertured partition between them. The second patent is for the continuous manufacture of volatile acids by means of the above furnace, for instance, that of hydrochloric acid from salt and sulphuric acid.—F. SODN.

Nitrates; Manufacture of —. W. A. Dyes, Manchester. From The Firm J. F. Lehmann, Muenich, Germany. Eng. Pat. 15,391, July 21, 1908.

CALCIUM nitrate is treated with a very slight excess of ammonium sulphate in aqueous solution, whereby practically all the calcium sulphate formed is precipitated, and after filtering, the clear solution of ammonium nitrate is evaporated. If the ammonium nitrate is required quite free from sulphate, its solution is first treated with the amount of barium nitrate, or baryta water, which is equivalent to the excess of ammonium sulphate present, after which it is filtered and evaporated.—O. R.

Cyanides from alkali or alkaline-earth oxides or carbonates, carbon, and nitrogen; Process for preparing —. N. Caro. Ger. Pat. 242,706, June 26, 1907.

It is known that the addition of a chloride to a mixture of carbon and an alkali or alkaline-earth oxide or carbonate facilitates the formation of cyanides. It is now found that fluorides possess the same property, and have the advantages over chlorides that they fuse at a higher

temperature, thus allowing the reaction to be carried out at temperatures above the point at which cyanide-formation takes place, without the melting of the mass; and also that the fluorides are not readily soluble in water, so that they can be easily removed from the products.

—T. F. B.

Zinc sulphide; Process of manufacturing — J. C. A. Meyer, Lyons. Eng. Pat. 25,965, Dec. 1, 1908. Under Int. Conv., Dec. 3, 1907.

ACCORDING to this invention, sulphuretted hydrogen is caused to react with a concentrated neutral solution of crude zinc sulphate, such as is obtained in metallurgical operations, until the solution is strongly acid and a state of equilibrium is reached. The operation takes place in two stages, first a slight current of the gas removing the heavy metals, and then, after filtration, pure zinc sulphide being precipitated by a second treatment. A large proportion of the zinc is precipitated, even from very concentrated solutions, and, being in contact with a strongly acid solution, the zinc sulphide is in a form which filters readily. The filtrate may be used for preparing a fresh solution of zinc sulphate.—F. SODX.

Lead arsenate; Manufacture of — E. E. Luther and W. H. Volek, Watsonville, Cal. U.S. Pat. 929,962, Aug. 3, 1909.

LEAD ARSENATES are produced in a single operation by roasting a mixture of white arsenic and a suitable lead compound, in combining proportions, in the presence of oxygen or an oxidising agent.—F. SODX.

Oxides; Process for reducing — [Preparation of the lower oxides of tungsten, molybdenum, vanadium, uranium, and titanium.] The British Thomson-Houston Co., Ltd., London, From General Electric Co., Schenectady, N.Y. Eng. Pat. 5821, Mar. 10, 1909.

CLAIM is made for the regenerative use of carbon monoxide as an agent for reducing the higher oxide of a metal to its lower oxide, particularly for the preparation of the lower oxides of tungsten, molybdenum, vanadium, uranium, and titanium. The metallic oxide is conveniently placed in a covered graphite or clay crucible which is entirely embedded in a carbon packing, contained in a larger crucible, also covered; the whole is then heated to 800° C. in a suitable furnace. Carbon monoxide is produced in the outer crucible and, rapidly diffusing through the heated inner crucible, reduces some of the metallic oxide; the carbon dioxide here formed passes back by diffusion and is once more converted into carbon monoxide by contact with the heated carbon, and complete reduction is thus soon effected. An advantage of the method is the absence of carbide or free carbon in the product. The process is very suitable for the preparation of tungsten dioxide for use in the production of lamp filaments.

—F. SODX.

Litharge; Method of making — J. E. Sullivan, Camden, N.J., Assignor to N.Z. Graves Co., Philadelphia, Pa. U.S. Pat. 931,522, Aug. 17, 1909.

"MONOXIDE of lead," obtained as a by-product in the manufacture of sodium nitrite, is heated for about 3 hours at 900°—1200° F., and the litharge thus produced is reduced mechanically to a "uniformly powdered commercial condition."—A. S.

Liquefaction of gas [air]; Apparatus for — G. A. Bobrick, Assignor to United States Liquid Air and Oxygen Co., Los Angeles, Cal. U.S. Pat. 924,137, June 8, 1909.

THE general plan of the apparatus is similar to that described in Fr. Pat. 499,416, Dec. 8, 1908 (this J., 1909, 939), except that, instead of free expansion being adopted in the ultimate liquefaction of the gas, means are provided for making one or both stages of the expansion as nearly as possible adiabatic. The details of an apparatus for the liquefaction of air, and its mode of working, are described by way of example. The devices previously indicated for the regenerative cooling of the high-pressure air and the jacketed coils of the liquefier are followed

by a separator and trap, in which liquid is separated from gaseous air; the latter is then admitted to an expansion engine, arranged within, or in close connection with, the liquefier itself, and in which the pressure is reduced from perhaps 300 to 60 lb. per sq. in.; the exhaust from this enters a second separator and trap, and liquid air passes thence to a receiver at low pressure, from which it may be withdrawn; from the first trap, the liquid is forced automatically and intermittently, as it accumulates into the second separator on the low-pressure side of the expansion engine, so that liquid cannot enter this machine. Part of the gaseous air from the second separator, at intermediate pressure, is utilised as a counter-current in the liquefier and coolers, and is then recompressed or passed through the external expansion engine to be used for further cooling, and part is allowed to undergo free expansion to atmospheric pressure, passing partially liquefied, to the final receiver, the gaseous portion returning through the outer envelope of the coils in the liquefier. For small plant, operated with pressures of 100—250 lb. per sq. in., the preliminary cooling of the external system may be effected by the circulation of expanded ammonia or some other refrigerating medium, and the liquefier may be constructed for expansion to take place in one stage, there being only one cooling jacket, surrounding the high-pressure spiral. In large plant, it may be desirable to provide means for both stages of the final expansion to be adiabatic.

—F. SODX.

Sulphur dioxide; Removal of — from gases and its recovery as sulphuric acid. H. Kühne, Goslar, Germany. Eng. Pat. 17,520, Aug. 20, 1908. Under Int. Conv. Aug. 20, 1907.

VIII.—GLASS, POTTERY, AND ENAMELS.

Glass tubing; Bursting strength of ——. J. R. Roebuck. *Physic. Rev.*, 1909, 28, 264—276.

To join glass-tubing and metal, the glass is to be first coated with a platinum film, and the latter is then electroplated with a coating of copper about 1 mm. thick; it is then "sweated" into a brass or iron tube. It is stated that such a joint can withstand a pressure of 670 atmospheres without leakage. Commercial glass tubing with thick walls, must be annealed to ensure the highest bursting strength. In cases in which the wall thickness was greater than the bore of the tube, the bursting strength was 1.3 times the tensile strength of the glass, or thereabouts, and to all intents and purposes independent of both the bore and the wall thickness.

PATENT.

Glass-making apparatus. P. T. Sievert, Dresden, Germany. Eng. Pat. 9853, April 26, 1909.

THE invention deals with machines for making hollow glass articles, and especially with apparatus for reheating previously-shaped glass bodies, carried by a frame attached to a body, before the final blowing in a mould (see Eng. Pat. 18,917 of 1904). In order to minimise the expense of having to provide different carrying-frames for the different shapes of objects made, the same vertically movable carrier is used for the different shapes, carrying-frames only of different design being attached to these carriers, either by mechanical means, or else by electromagnetic devices. The frames are also supported in such a way that the space between carrier and frame can be altered at will.—A. G. L.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

Calcareous asphaltum and paving mixtures; Analysis of ——. Prettnr. *Chem. Zeit.*, 1909, 33, 917—918, 926—927.

THE author's results show that utterly erroneous values may be obtained for the gypsum present in asphaltum, if the gypsum be determined in the ash obtained by burning off the organic matter. During the ignition the "organic" sulphur reacts with any calcium carbonate present, with formation of calcium sulphate and sulphide. To determine the gypsum actually present, the mineral matter should be extracted by means of a special reagent, prepared by gradually adding about 300 c.c. of ether to 200 c.c. of hydrochloric acid (sp. gr. 1.19), with continual shaking and cooling, until no more ether is taken up by the acid. 15 c.c. of this reagent are gradually added in 3 or 4 portions to 1 or 2 grms. of the sample of asphaltum, contained in a 150 c.c. flask, placed in an inclined position. The whole is then stirred for 8—10 minutes with a flattened glass rod, 5 c.c. of ether being added during the stirring; 10—15 c.c. of water are then added and the stirring continued until decomposition is complete, after which 40—50 c.c. of hot water are added, and evaporation of the ether is completed by immersing the flask in hot water. The flask is then cooled, the aqueous solution decanted through a filter, and the residue washed 2 or 3 times with very dilute hydrochloric acid. In the filtrate gypsum is determined as usual. To determine total sulphur, 0.5—1 gm. of the finely powdered sample is gently heated with 7 grms. of sodium peroxide in a loosely covered nickel crucible. As soon as the reaction is over, the crucible is strongly heated for 5 minutes. The contents are then dissolved in hot water, the excess of peroxide decomposed by boiling, and an excess of hydrochloric acid and barium chloride added. The silica present does not interfere with the estimation. To determine the organic matter, two portions of 1—2 grms. each are decomposed as for the determination of

gypsum. The aqueous liquid from one portion is decanted through a filter-paper as before, and flask, glass rod and filter are dried, after washing, at 110° C. By the aid of 6 or 7 portions of 2—3 c.c. each of chloroform, the organic matter is then completely transferred to a platinum crucible; the solution is evaporated by heating and directing a current of air against the crucible, and the residue weighed after drying at 105°—110° C. The organic matter is next incinerated; the difference in the weights corresponds to the total organic matter present. The aqueous solution from the second flask is decanted through an Albin filter-tube; the flask and filter are dried, and the soluble organic matter only is obtained by digesting the contents of the flask with successive small quantities of chloroform, which are decanted through the filter-tube. The solution so obtained is evaporated as before, and the residue incinerated, the difference in weight giving the organic matter soluble in chloroform. The lime in the ash should always be converted into calcium sulphate, as variable quantities of the latter are produced during the ignition of the organic matter. Some analyses of Continental samples of asphaltum are given in the paper.

—A. G. L.

Clays; Experiments with ——. Rohland. *Speichsal.*, 1909, 42, 469—470.

ON bringing air-dry clays into sudden contact with a liquid, the clays are disintegrated more or less completely, liquids with a low viscosity having much more action than liquids with high viscosity. The following liquids act with intensity decreasing in the order named: ether, water, benzene, chloroform. The nature of the organic substance which gives clays their peculiar taste and smell is unknown. The substance can, however, be removed from clays by shaking the latter with an aqueous solution of ferric saccharate (i.e., ferric hydroxide dissolved in a solution of sugar). Bonis has previously connected this substance with the ammonia contained in clays, the peculiar smell being first augmented on treating the clay with potassium hydroxide solution, and then disappearing when the ammonia has been expelled.—A. G. L.

Portland cement; Rise in temperature during the setting of ——. Hossbach. *Tonind. Zeit.*, 1909, 33, 1983—1990.

THE rise in temperature during setting was determined with two cements of normal composition, one a slow-setting, the other a quick-setting cement. Tests were made on the neat cements, on sand (3:1) mortars, and on the same sand mortars after keeping them for 24 hours and then again mixing them with water. The tests were made by placing the gauged samples in vessels of sheet zinc surrounded by non-conducting material, and noting the temperature, at first every 5 minutes, and afterwards every 10 minutes. For each sample four different vessels were used, the smallest holding 142 c.c., or about the volume used for a Vicat needle test, the next 1420 c.c., the third 14,200 c.c., and the largest 142,000 c.c. In every case there was a rise of temperature during the gauging; with the smallest sample, a fall in temperature to practically room temperature then occurred, followed by a second rise in temperature, whilst with the three larger samples the initial rise was continued, although at a slower rate at first, to the maximum temperature. With the largest sample of the neat quick-setting cement, the maximum temperature reached exceeded 100° C. It was shown that the fall in temperature observed with the smallest (142 c.c.) samples was due only to the rate of cooling exceeding the heating produced by the reaction, and was not a real fall. For this purpose, samples of the same size were placed in water-tight vessels, which were immersed in water, the temperature of which was kept 0.2—0.3° C. below that of the cement, by the gradual addition of hot water. In this way, the rise in temperature obtained was continuous from the initial rise to the maximum temperature; here also a period was observed during which the rise slackened. It was found that the time which elapsed before the maximum temperature was reached, varied considerably for the different sized samples and for different mixtures, and was generally quite different from the initial or final

setting-times as indicated by the Vicat needle. It was also found that the mortars which were gauged a second time after keeping, developed but little heat after the second gauging, and gave very poor tensile and compression tests; it follows from this that mortars should be used as soon as possible after gauging.—A. G. L.

Cements; Determination of free lime in —. R. Brandenburg. Chem.-Zeit., 1909, 33, 880.

For the determination of free lime in cements, the author recommends boiling with a saturated solution of ammonium bromide in absolute alcohol, and estimating the ammonia produced. Ammonium bromide was not decomposed on boiling its alcoholic solution either alone or in presence of calcium carbonate. The absolute alcohol was produced by first distilling in presence of quicklime and then allowing to stand in contact with "activated" aluminium until evolution of gas could no longer be observed.—A. S.

PATENTS.

Abrasive material; New — and the process of its manufacture. J. Brightmore, Tideswell, Derbyshire, Eng. Pat. 3546, Feb. 13, 1909.

BLACK basalt is heated to a high temperature for about four hours in a suitable kiln or furnace, and is then fluxed by adding to it powdered fluorspar and reheating for a further two hours. The mixture is cooled by spraying with water, crushed, and pulverised.—O. R.

Wood; Method of treating —. W. B. Chisholm, Charleston, S.C., U.S.A. Eng. Pat. 5908, Mar. 11, 1909.

A SOLUTION, claimed to contain free sulphur in solution, is obtained by boiling together 4 parts by weight of sulphur and 1 of lime with water. The red solution obtained is filtered or decanted, and the filtered solution, heated to its boiling-point is used for impregnating wood, preferably immediately after preparation. On cooling, sulphur and calcium salts are deposited in the pores of the wood. Sodium, potassium, or ammonium hydroxide may be substituted for the lime. If the wood is to be used below the surface of water, it is, in addition, painted over with a fused mixture obtained by melting 4 parts of sulphur with 1 of lime.—A. G. L.

Wood; Process for impregnating —. W. A. G. von Heidenstam and K. L. F. Friedemann. Fr. Pat. 339,712, Jan. 26, 1909. Under Int. Conv., Feb. 15, 1908.

WOOD is impregnated with an aqueous solution of compounds of the cresols with lime. The impregnated wood is then exposed to the action of the air, or of flue-gases, when the cresols are liberated within the wood, with simultaneous formation of calcium carbonate.—A. G. L.

Mastic for paving; Method of manufacturing a —. J. H. Amies, Assignor to The Amies Asphalt Co., Philadelphia, Pa. U.S. Pat. 929,813, Aug. 3, 1909.

A MIXTURE of a base such as calcium oxide or hydroxide with mineral, earthy or fibrous material is added to asphaltic, resinous, or other carbonaceous material and the whole mixed with moist sand, and, if necessary, water, to produce a granular and friable mastic. A volatile oil may be mixed with the mineral ingredients before adding the bituminous material.—A. G. L.

Refractory substances; Process relating to —. R. Tripmacher, Schweidnitz, Germany. U.S. Pat. 930,575, Aug. 10, 1909.

POWDERED refractory substances are agglomerated by treatment with a liquid consisting of a saccharine solution and a chromium compound (chromic acid) emulsified with naphtha. A boron compound (boric acid) and a fluoride may also be added.—A. G. L.

Refractory bricks; Method of producing — from lime, silica or similar materials. S. W. Berglund. Fr. Pat. 399,384, Feb. 11, 1909.

QUARTZ, preferably finely divided, is first heated to about 1500° C. It is next powdered as finely as possible, mixed

with 2—6 per cent. of lime, and treated as usual in making sand-lime bricks. It is claimed that the bricks obtained are very refractory and undergo no change in volume on heating.—A. G. L.

Porous material [from slate]; Method of manufacturing a —. H. Senn, Szczakowa, and D. Klüger, Trzebinia, Austria-Hungary. U.S. Pat. 930,801, Aug. 10, 1909.

SLATE containing about 10 per cent. of organic matter is calcined at about 1200° C., whereby the material swells and assumes a cellular structure.—A. G. L.

Stones of all kinds; Process for the uniform colouring of —. W. Tapolski. Ger. Pat. 212,874, May 24, 1908.

ALKALI salts or ammonium salts, preferably of organic acids, are added to the metallic salt solutions used for producing coloured precipitates in the stones, in order to facilitate their penetration.—A. S.

Hydraulic lime; Process of making artificial —. N. Lambert. Fr. Pat. 399,848, Feb. 23, 1909.

THE lime-dust from lime-kilns is mixed with materials containing silica, alumina, and alkali in proportions suitable for a hydraulic lime.—A. G. L.

Slag cement; Manufacture of —. J. G. A. Rhodin, Liverpool. Eng. Pat. 23,988, Nov. 9, 1908.

MOLTEN slag is disintegrated by being caused to impinge on to the surface of a rapidly rotating disc or table, enclosed in a chamber into which finely divided salts, such as ferrous sulphate, are forced by means of an atomiser spray. The minute globules of slag chemically combine with the dry salts, forming a cement clinker, which when cooled and ground, is readily hydrated.—F. R.

Cement; Method of making an acid-proof —. H. Kayser, Darmstadt, Germany. Eng. Pat. 24,718, Nov. 17, 1908.

PORTLAND cement is mixed with the residue obtained in working bauxite, which contains soluble silica, or with infusorial earth.—A. G. L.

Cement; Treatment of stony or earthy materials, particularly for the manufacture of —. F. L. Smidth and Co., Copenhagen, Denmark. Eng. Pat. 2599, Feb. 3, 1909. Under Int. Conv., Feb. 27, 1908.

CEMENT raw materials, etc., are first crushed, with the addition of a certain amount of water, in a ball-mill, preferably of the kind in which the pounding force of the balls is utilised in addition to the friction between the materials and the balls. The crushed material is delivered to a stationary sieve provided with centrifugally acting stirrers, which force the slimes through the sieve; these stirrers consist essentially of hollow arms for feeding the material, and flat wings for beating it against the sieve. The slimes are delivered directly to the rotary kiln, or, preferably, to a tube-mill, in which they are ground finely, whilst the coarse particles are returned to the ball-mill.—A. G. L.

Portland cement; Apparatus for burning —. T. A. Edison, Llewellyn Park, Orange, N.J. U.S. Pats. 930,946, 930,948, and 930,949, Aug. 10, 1909.

A ROTARY cement kiln is provided with means for introducing the cement material diametrically across the kiln and directly in the path of the products of combustion of gas from a producer connected to the lower end of the kiln. The gases emerge from the kiln into a settling chamber of such size as to greatly reduce their velocity, so as to allow the coarser particles of dust to settle. Opposing walls of this settling chamber are made of loose granular material and form filters on which the fine dust is deposited, the products of combustion being drawn through the filters by the action of controllable exhaust fans. The dust-free products of combustion may be led to a heat-absorbing device, e.g., a feed-water heater, a by-pass arrangement being provided by which the gases can be shunted, if desired.—(See also U.S. Pat. 930,947, page 973.)—A. G. L.

Concrete compound; Process of producing a fire-proof — S. von Medvecsky, Arad, Hungary. Eng. Pat. 27,902, July 29, 1908.

A FIREPROOF concrete suitable for making stoves, etc., is obtained by mixing 2.5 parts of sand with 1.5 parts of a mixture consisting of 1 part of kaolin, 0.34 of soapstone and 0.16 of pumice stone, ashes, or lava, and 0.5 parts of Portland or other cement. Water, preferably in the form of steam, is added, and the whole moulded. To produce a porous product, 0.05 part of sodium chloride, borax, or other salt, or of lime, is added to the above. Clay may be substituted for a part or the whole of the concrete mixture.—A. G. L.

Concrete or cementitious compounds; Process of, and apparatus for, making — L. M. Reed, Cleveland, Ohio. U.S. Pats. 930,085 and 930,086, Aug. 3, 1909.

THE process claimed consists in mixing sand with hydraulic Portland cement, and "showering" the dry mixture into a stationary body of liquid. The apparatus consists of a receptacle open at the top and closed at the bottom or holding liquid; of an inverted T-shaped bar rapidly moving to and fro across the receptacle and some distance above it; of screens placed between the path of the bar and the top of the tank; and of means whereby the constituent materials of the concrete mixture are fed into the path of the bar.—A. G. L.

Food; Process of impregnating — H. A. Mueller, Malmö, Sweden. Eng. Pat. 2534, Feb. 2, 1909. Under Int. Conv., Feb. 15, 1908.

EE Fr. Pat. 399,712, preceding.—A. G. L.

Lithographic stone; Manufacture of — artificially. T. M. Thom, Cheshunt, Assignor to The British Stone and Marble Co., Ltd., London. U.S. Pat. 927,822, July 13, 1909.

EE Eng. Pat. 15,964 of 1907; this J., 1908, 859.—T. F. B.

Cement, mortar, and concrete; Method of making — water-tight. P. Mecke, Stettin, Germany. U.S. Pat. 929,152, July 27, 1909.

EE Ger. Pat. 200,968 of 1908; this J., 1908, 1021.—T. F. B.

Cement; Rotary kiln for burning — F. J. Poths, Hamburg, Germany. U.S. Pat. 929,167, July 27, 1909.

EE Fr. Pat. 391,454 of 1908; this J., 1908, 1154.—T. F. B.

X.—METALS AND METALLURGY.

Nickel-steel for bridges. J. A. L. Waddell. Proc. Amer. Soc. Civil Eng., 1908, 34, 726—923. Proc. Inst. Civil Eng., 1908—1909, 176, [2], 9—10.

INVESTIGATIONS and experiments upon the relative value nickel- and carbon-steel for bridges were carried on over period of three years.

The first step was to ascertain the percentage of nickel which would give the best results. This is limited by the fact that, if high, the material becomes too refractory for shop-working. The best percentage was found to be 5. The allowance of impurities in the nickel steel was as follows:—Phosphorus, 0.03 per cent.; sulphur, 0.04 per cent.; silicon, 0.04 per cent. The allowance of manganese was 0.75 per cent. to 0.85 per cent. The results of the tests upon low nickel-steel were, as an average of eleven tests, 61,300 lb. per square inch for the elastic limit, and 130,300 lb. per square inch for the ultimate strength. For high nickel-steel these figures were 71,600 and 114,000 lb. per square inch, respectively. Impact tests showed that the resistance of nickel-steel was less than that of carbon-steel, the relative values being 87 and 73 to 100, for low and high nickel-steel. Other tests such as hammering, drifting, close-punching, shop-tooling, and corrosion tests were also made.

The author concludes that, at present prices, it would be more economical to use nickel-steel for all kinds of railway bridges, and the larger the bridge the greater the economy. It would also be possible to construct bridges of greater

span with nickel-steel. It is generally regarded that the limit of span for carbon-steel bridges is 2000 feet, but with nickel-steel this could be increased to 2600 feet.

Iron; Peroxidation of — in [copper] blast furnaces. A. Rizo-Patron. Eng. and Min. J., 1909, 88, 367—368.

THE unsatisfactory results obtained in attempting to smelt certain pyritic copper ores, in the raw state, is said to be due to the formation of iron peroxide, instead of protoxide, in the slag. The author describes the attempt made to smelt an ore consisting of grey copper ore, copper and iron pyrites and a very little blende, in a silicious gangue. No difficulty was found in smelting the ore after it had been partially roasted, a matte containing about 35 per cent. of copper being obtained together with a good fluid slag. When, however, the same ore was smelted in the raw state, it was found impossible to produce a fluid slag, although the composition of the pasty, semi-magnetic slag formed, closely resembled (on the assumption that the iron was present as ferrous oxide) that of the fluid slag obtained from the partially roasted ore. It was found that the iron in this particular ore was very readily converted into the magnetic oxide, Fe_3O_4 , even at the low temperature of roasting, so it is thought that the iron tends to become peroxidised by the furnace blast, with the formation of infusible ferric silicate. When partially roasted ore is fed into the furnace, the peroxides already existing are reduced in the upper part of the furnace, and they, with the sulphates, react with the remaining sulphides, preventing the formation of magnetic oxide of iron. Mixing raw ore with roasted ore has the same effect.

—F. R.

Copper smelting; Theory of — N. Juschewitsch. J. Russ. Phys.-Chem. Ges., 1909, 41, 469—472. Chem. Zentr., 1909, 2, 761.

EXPERIMENTS in an electric furnace in an atmosphere of nitrogen showed that the reaction: $\text{Cu}_2\text{O} + \text{FeS} = \text{Cu}_2\text{S} + \text{FeO}$, begins at $280^\circ\text{--}285^\circ\text{C}$. and proceeds rapidly to completion at 700°C . The reaction: $2\text{CuO} + \text{FeS} = 2\text{Cu} + \text{Fe} + \text{SO}_2$, will take place at 455°C ., but is not complete even at 770°C .; the highest yield attained was 96 per cent. In the reaction: $\text{Cu}_2\text{S} + \text{Fe} = \text{FeS} + 2\text{Cu}$, at 600°C ., scarcely 6 per cent. of the sulphur of the cuprous sulphide combined with the iron, whilst in the reverse reaction: $2\text{Cu} + \text{FeS} = \text{Cu}_2\text{S} + \text{Fe}$, at the same temperature, 26 per cent. of the sulphur of the ferrous sulphide combined with the copper in 6 hours.—A. S.

Bronzes; Method for the analysis of — by electrolysis. A. Fischer. Z. Elektrochem., 1909, 15, 591—595.

FOR the analysis of bronze, 0.5—0.6 gm. of the very fine filings is slightly warmed with a solution of 6 grms. of tartaric acid and 1 gm. of monochloroacetic acid, strong nitric acid, to a total quantity of 2—2.5 c.c., being added from time to time. In presence of monochloroacetic acid, the alloy dissolves more rapidly, and the stability of the resulting solution is increased. The solution is made just alkaline with sodium hydroxide, warmed to 90°C ., and acidified with 2 grms. of tartaric acid. Separation of the copper is then effected by Sand's electrolytic method (this J., 1907, 490; 1908, 963), the solution being heated to its boiling point; for the last traces of copper a cathode potential of 0.7—0.8 volt, determined with the mercurous sulphate electrode, instead of 0.45—0.55 volt, as recommended by Sand, is necessary. The deposition of the copper is complete in 20—30 minutes. The solution, free from copper, is concentrated to about 120 c.c., and then rendered ammoniacal and mixed with 5 grms. of very pure ammonium sulphate; about 16 c.c. of ammonium sulphide and 2—3 grms. of sodium sulphite, to reduce polysulphides, are added, and the liquid is gently boiled for 5 minutes, with vigorous stirring. The sulphides of lead, zinc, and iron, thus precipitated, are filtered off and dissolved in nitric acid; the lead is separated by a known method, the solution is evaporated with sulphuric acid, and the zinc, after precipitation of iron as hydroxide, is reduced from alkaline solution. The tin is obtained, quite pure, by electrolysis the solution of the sulpho-salt at $40^\circ\text{--}50^\circ\text{C}$., first for 5—10 minutes with a current of about 3 amp., without

stirring, and then at 5 amp., with the stirrer rotating at about 500 revolutions per min.; the tin is deposited on a platinum cathode, which has been coated first with copper and then with tin. During electrolysis, which is complete in 20–30 minutes, sodium sulphite is added, as required. The whole analysis takes about 5 hours.—F. SOPN.

Tin and gold production of the Federated Malay States.
Board of Trade J., Sept. 9, 1909. [T.R.]

THE following particulars of the production of tin in the Federated Malay States in 1907 and 1908 are extracted from the report on the mining industries of the States for 1908, published as a Supplement to the "Selangor Government Gazette" of 30th July:—

State.	1907.		1908.	
	Quantity.	Value.	Quantity.	Value.
	tons.	£	tons.	£
Perak	25,678	4,292,008	27,844	3,644,504
Selangor	16,304	2,725,123	16,818	2,201,270
Negri Sembilan ..	4,473	747,738	3,823	500,347
Pahang	1,976	330,267	2,352	307,897
	48,431	8,095,136	50,837	6,654,018

The fluctuation of local prices in 1908 was between 73·37 dols. (on 26th March) and 59·00 dols. (on 4th January), as compared with 97·25 dols. (on 29th April) and 57·75 dols. (on 18th December) per picul in 1907. The average price was 66·78 dols., as compared with 85·28 dols. in 1907. (Dollar = 2s. 4d.)

Exports of tin during the first six months of 1908 and 1909 amounted to 24,600 tons and 22,800 tons respectively.

The output of gold during 1908 was 14,886 ounces, as compared with 15,353 ounces in 1907, a decrease of 467 ounces. The amount for each State was as follows:—

	1907.	1908.
	ozs.	ozs.
Perak	1,032	1,234
Selangor	35	Nil
Negri Sembilan ..	Nil	Nil
Pahang	14,286	13,652
	15,353	14,886

The figures for Perak show the production, but those for Pahang the exports. In addition to the above, there were exported from Negri Sembilan about 100 ounces of gold won on Kanaboi Limited land, the fineness and value of which had not been ascertained. A certain amount of gold (probably 1,000 ounces) was also won by Malays, working in Ulu Pahang under individual licences, but was not exported.

Uranium mining at Joachimsthal. Engineering, Sept. 10, 1909. [T.R.]

THE two uranium mines belonging to the Saxon company are the *Gewerkschaft Hilfe Gottes-Zeche*, which started operations in 1852, and the *Gewerkschaft Sächs Edelleutstollen*, which commenced in 1856. The two lodes of the latter mine now being principally mined are worked by an adit 1000 metres long, partly driven, so it is said, at least 600 years ago. The lodes are of variable width, ranging from 3½ yards to 1 in., the pitch-blende occurring as detached lumps embedded in the mica-schist. Some of these lumps may weigh several pounds, but a large amount of the ore mined does not run above 3 or 4 per cent. of uranium oxide.

The dressing plant at the mine is of somewhat rough construction, but appears to give satisfactory results. In the case of the rich ore very little treatment is required, hand-picking being followed by grinding in a ball mill, the product assaying about 60 per cent. uranium oxide. The poorer ore goes to a crusher preparatory to being fed to a battery of wooden stamps, from which it is taken on to a series of wooden percussion tables. These tables, which

are made on the spot, are actuated by cams on a 3-diameter wooden driving-shaft. The ore from the tables assays on an average 55 per cent. uranium oxide.

The bulk of the ore from these two mines is sold to the factory of the Austrian Government, who are now utilising the old silver-smelter near the new railway station as uranium factory. Practically the only competitive uranium works to those at Joachimsthal are at Brunswick where the radium salts are to be extracted from the Cornish pitch-blende.

Up to the present, for a considerable number of years the market prices of uranium salts have been entirely in the hands of the Austrian Government, the output of Saxony having dwindled considerably. As America and Spain contribute only a few tons of very low-grade ore there are only the two producing districts of Joachimsthal and Cornwall to be considered. Statistics show that in 1906, Austria produced 16 metric tons of ore, valued £10,901, while the Cornish output in 1906 was 11 tons of a value not stated. In 1907 the Cornish figure was 10 tons, valued at £6500, and the advance statistics for 1908 show very similar figures.

PATENTS.

Iron or steel; Treatment of — for preventing oxidation or rusting. Coslett Anti-Rust Syndicate, Ltd., and T. W. Coslett, Birmingham. Eng. Pat. 15,628, July 2, 1908.

IRON or steel articles, on which a coating of phosphate of iron has been deposited (see this J., 1907, 207) are digested in a solution of chromic anhydride for periods depending on the strength and temperature of the solutions. Cold solutions of one-third to 2 per cent. require from 10 to 30 minutes, while hot solutions of one-sixth of 1 per cent. or less, only require 5 minutes.—F. R.

Coating of iron or steel with copper or other metal, such as silver or gold, which will readily alloy with copper. W. C. Clark, Geelong, Australia. Eng. Pat. 16,820, Aug. 1, 1908.

THE article to be coated is "pickled," if necessary, in mineral acid, and then immersed in a saturated solution of cupric sulphate for 10 minutes. It is then dried, heated and passed into a bath of molten copper, or other suitable metal, upon which floats a layer of flux consisting approximately of 15 parts of boric acid, 13 parts of hydrofluoric acid, 4 parts of potassium tartrate, and 4 parts of ammonium chloride, with or without the addition of borax, alum, nitre, silica or soda (sodium carbonate).—F. R.

Titaniferous iron ores; Process of treating —. W. Borchers, Aix-la-Chapelle, Germany. U.S. Pat. 930,344, Aug. 10, 1909.

TITANIFEROUS iron ore is first smelted with carbon, and the reduced crude iron drawn off. The slag, rich in titanium, is converted into a reducing agent by strongly heating it with carbon and is then mixed, at a temperature of about 2000° C., with subsequent charges of ore, which are thereby reduced to silicious iron free from titanium and a slag rich in titanium and poor in silicon.—F. R.

[Iron-tungsten] alloy for making projectiles, &c. J. C. Wyckoff. Fr. Pat. 399,666, Feb. 20, 1909.

THE alloy consists of 21–33 per cent. of tungsten and 79–67 of iron. It is claimed that its high specific gravity and great hardness confer high ballistic properties on the alloy.—A. G. L.

Iron and steel waste; Transformation of — into cast steel. Soc. Anon. des Acieries de Franco. Fr. Pat. 400,382, June 2, 1908.

THE waste is smelted in presence of coke, anthracite, or some such material, a hot or cold blast being employed and limestone, fluorspar or alkaline salts being added if necessary. By the carbonisation of the metal in this way, an intermediate product is obtained, which is particularly suitable for transformation into steel by the ordinary methods of refining. If desired, a certain quantity

ity of new or waste cast iron may be added in the preliminary smelting, the principle of the operation remaining the same.—C. A. W.

Steel; Carbonisation of — to an exact carbon content. C. A. Keller. Fr. Pat. 400,461, June 6, 1908.

A STRONGLY compressed prismatic block of agglomerated carbon is suspended within the furnace by means of a cable passing through an aperture in the roof and wound over a winch or some such lifting device. The block is suitably balanced and arranged so that it may be raised, or lowered through the floating slag into the mass of liquid metal. A dynamometer is attached to the cable, or to the lifting apparatus, so that, as the carbon dissolves, the loss in weight may be read off directly, at any moment. In this way, knowing the weight of metal in the furnace, the content of carbon may be exactly regulated.—C. A. W.

Tin; Apparatus for extracting — from tin plate waste. H. Brandenburg, Kempen on Rhine, Germany. Eng. Pat. 16,895. Aug. 11, 1908. Addition to Eng. Pat. 2322 of 1908.

A place of removable perforated containers arranged between T-irons mounted on a rotating spindle (see his J., 1908, 813), two concentric drums are arranged about one spindle and the annular space between the two drums is used to contain the tin-plate scrap, which is caused to rotate in the caustic alkali lye. Access to the annular space is provided by a portion of the outer drum opening by means of a hinge, or an end segment being removable.—F. R.

Terpene-oil; Apparatus for recovering — from water-bath. [Tinning metal articles.] V. Fornozini, New Britain, Conn. U.S. Pat. 929,204, July 27, 1909.

A oil bath adapted for dipping articles in the process of tinning is so combined with a water bath that the articles after treatment in the oil bath can be cooled in running water. The oil which thereby accumulates in the water is recovered by allowing it to overflow together with some water, in a wide and shallow flow, into a separating vat, from the bottom of which the water is siphoned off, whilst the oil collects on top and may be drawn off through a suitable outlet.—R. L.

Lead or other metal or alloy in a thread-like or finely divided form; Process of producing —. E. P. Richford, London. Eng. Pat. 22,092, Oct. 19, 1908.

LEAD in a finely divided thread-like form, for use as packing in secondary batteries, etc., is obtained by melting the metal in a closed vessel, provided near the bottom with a lateral discharge pipe having perforations on its upper side, through which the lead is extruded by pneumatic pressure. The container and discharge pipe are separately heated to ensure fluidity of the metal, and if necessary cold air or water may be applied to cool the filaments as they immerge.—F. R.

Steam from the heat contained in slags; Generation of —. C. Vautin, London. Eng. Pat. 3623, Feb. 13, 1909.

WET steam is caused to flow through a trapped inlet to an enclosed vessel containing water. The low-pressure steam thus produced is conveyed to a low-pressure turbine, passing on its way, the incoming wet steam, which heats and dries it; the disintegrated slag is continuously removed by a conveyor. In order to more effectually granulate the slag, a circulating pump is arranged to discharge a stream of water directly against the incoming molten slag.—F. R.

Aluminium; Flux for use in soldering — with ordinary tin and lead solder and copper bit. W. G. Jeffery, Charlton, Kent. Eng. Pat. 8272, April 6, 1909.

THE flux is made by heating to boiling a mixture of one part of sal-ammoniac, three parts of glycerin, and four parts of water. The soldering bit is tinned in the usual way with the aid of the flux and the solder dipped in the flux and melted on the point of the bit. The fluxed solder

softens the oxide which is readily removed by rubbing with the point of the bit, its place being immediately taken by the solder.—F. R.

Aluminium; Solder for —. Z. Tamassy, Assignor to Z. B. Csiky and E. Ots, Cleveland, Ohio. U.S. Pat. 931,523, Aug. 17, 1909.

A SOLDER for aluminium is made by fusing together 130 grains of antimony, half a pound of zinc, half a pound of tin, and 44 grains of salicylic acid.—F. R.

Aluminium alloy; Unoxidisable — for making bearings, lugs, tyres, etc. V. Etienne. Fr. Pat. 399,928, Feb. 26, 1909.

THE alloy consists of: Aluminium, 75 parts; cadmium, 12; copper, 6; tin, 5; and nickel, 2 parts. The proportions may be varied, and the nickel or tin omitted if the ductility of the alloy is to be increased.—A. G. L.

Argentiferous lead ores; Treatment of —. O. H. Picher, Joplin, Missouri. U.S. Pat. 920,388, May 4, 1909.

SULPHIDE ores, mixed with carbon, are treated at a comparatively low temperature, in open-hearth furnaces, in a combined oxidising and reducing atmosphere. The gaseous products of the furnace, together with the admixed fume, pass through a series of settling and cooling flues, in which the argentiferous dust collects, the practically non-argentiferous blue fume being carried over and subsequently caught by screens. The lead fume is strongly heated in a combined oxidising and reducing atmosphere for the production of sublimed white lead and pig lead.—F. R.

[Metallic] Coated metal objects; Process of producing —. J. F. Monnot, Assignor to Duplex Metals Co., New York. U.S. Pat. 929,777, Aug. 3, 1909.

COATED metal objects consisting of unlike metals inseparably united are produced by pouring one metal, heated much above its melting point, into a suitable mould containing a highly heated solid body of the other metal submerged in an inorganic "wiping" material. The molten metal displaces the "wiping" material and solidifies in contact with the solid body.—F. R.

Compound metal body and process of producing same. J. F. Monnot, Assignor to Duplex Metals Co., New York. U.S. Pat. 929,778, Aug. 3, 1909.

COMPOUND metals consisting of a metal of the light metal group, such as aluminium, inseparably united to a ferrous metal (iron) are produced by bringing a body of such ferrous metal into contact with a supermolten mass of metal belonging to neither group, such as copper, and then bringing the coating so formed into contact with a molten mass of aluminium, or the like, and causing a layer to solidify thereon.—F. R.

Furnace; Ore-roasting —. A. R. Willley, Denver, Colo., Assignor to J. Seep, Titusville, Pa. U.S. Pat. 930,254, Aug. 3, 1909.

THE furnace consists essentially of a vertical chamber in which two pipes are arranged to conduct air from a conduit situated near the bottom, and open to the outer air, up the entire length of the chamber, meeting the falling ore as it is charged, by means of a hopper, into the top of the chamber. Means are provided for introducing heat to the ore at the top of the furnace.—F. R.

Iron and steel; Process for rustproof coating —. Langbein-Pfahhauser-Werke Akt.-Ges., Leipzig-Sellerhausen, Germany. Eng. Pat. 26,521, Dec. 8, 1908. Under Int. Conv., Dec. 21, 1907.

SEE Fr. Pat. 395,409 of 1908; this J., 1909, 480.—T. F. B.

Analysis of bronzes by electrolysis. Fischer. See X.

Formation of butyric acid from, and fixation of nitrogen by alcohol, under the influence of the silent electric discharge. Löb. See XX.

PATENTS.

Ozone; Production of —. M. P. Otto, Paris. Eng. Pat. 16,542, Aug. 5, 1908. Under Int. Conv., Aug. 5, 1907.

THE apparatus consists of a number of interchangeable elements, grouped, by means of travelling supports, upon a common frame. Each element consists of two outer low-tension plates and a central high-tension plate

dielectrics being provided between the central and the outer plates. Both high and low tension plates are made hollow and cooled by circulating water through them. A modified form consists in substituting a single metal plate for the dielectrics applied to either the high or low tension plates, together with the corresponding plate. —F. R.

Electrodes for use in electrolysis. C. C. Connor, Belfast, and J. W. Stubbs and The Electrolytic Alkali Co., Ltd., Middlewich. Eng. Pat. 23,930, Nov. 9, 1908.

THE electrode is constructed of two separated straight metal bars, connected at intervals to cross-bars of carbon by means of lead or other metal castings. Removable distance pieces are placed between the metal bars, thus forming, with the latter, moulds round the cross-bars for casting the lead. The conductor bars are covered with an insulating material impervious to the electrolyte, and finally with Portland cement. The ends of the carbon nipples are furnished with carbon blocks.—B. N.

Depolarisers for electric batteries. G. Schauli, London. Eng. Pats. 24,355 and 24,356, July 9, 1908.

(1). PHLORIDZIN ($C_{21}H_{21}O_{10}$) is added, as a depolariser, to the active ingredients of the battery with a view to preventing the liberation or escape of gases. Phloridzin is stated to have the property of absorbing ammoniacal gases to about 14 per cent. (2). Metallic manganese is melted and heated strongly for about 5 hours in a plumbago crucible until it combines with a portion of the carbon of the crucible. On cooling or pouring into moulds, a mass of carbonised metallic manganese is obtained, together with a manganese oxide ("carbon-manganic oxide") in the form of a black powder. The latter forms the new depolariser.—J. W. H.

Batteries; Electric —. H. de Martis, London. Eng. Pat. 26,285, Aug. 17, 1908.

THE invention relates to the use of a separating medium between the plates or electrodes of secondary electric batteries. This consists of vegetable woven fabric, from which the foreign matter, such as fat, resin, wax, pectic acid or the like, has been extracted, thus leaving only the fibrous portion of the material. The extraction may be performed with an ammoniacal copper solution, alcohol, or ether, or by continuous boiling, preferably under pressure.—B. N.

Electrolyte. A. Van Winkle, Assignor to The Hanson and Van Winkle Co., Newark, N.J. U.S. Pat. 930,815, Aug. 10, 1909.

THE electrolyte comprises a solution containing zinc fluosilicate, another salt of zinc, a salt of aluminium, and a small quantity of gelatin previously dissolved. —B. N.

Storage-battery elements; Process of preparing —. D. P. Perry, Chicago, Ill., Assignor to W. Morrison, Chicago, and M. A. Lombard, Des Moines, Iowa. U.S. Pat. 931,081, Aug. 17, 1909.

COPPER and cadmium are precipitated together as "hydrates" from a nitric acid solution containing 1 part of copper and 2 parts of cadmium. The precipitate is washed, dried, and secured to a suitable support for forming an element of a storage battery.—J. W. H.

Electrolytes; Process of preparing alkaline — for storage batteries. D. P. Perry, Chicago, Ill., Assignor to W. Morrison, Chicago, and M. A. Lombard, Des Moines, Iowa. U.S. Pat. 931,082, Aug. 17, 1909.

THE battery is filled with an alkaline zincate solution and charged, when zinc is deposited on the positive element. The electrolyte is then replaced by a "purified alkaline solution" and the battery discharged. By this means a suitable alkaline zincate electrolyte is regenerated. —J. W. H.

ases; Apparatus for treating — by electricity. I. Moscicki, Fribourg-Gambach, Switzerland. U.S. Pat. 930,212, Aug. 3, 1909.

THE electric furnace comprises a furnace chamber, with means for supplying the untreated gases and removing the gases after treatment, so that a continuous flow takes place through the chamber. The gas is made to pass through an annular electrode, the latter having "an inward-projecting edge lying in a plane transverse to the flow of the gases," and a second electrode with a plate-like terminal is placed concentric with, and within arcing distance of, the annular electrode, the plate-like terminal being in the direction towards which the gases flow. Means are provided for starting the arc, and for imparting a angular movement to the circular arc formed between the adjacent edges of the electrodes. A magnetic field produced by suitable means, the flux of the lines of force cutting the circular arcing space through which the gases flow.—B. N.

ases; Apparatus for generating — by electric discharges in air. J. E. Mitchell, St. Louis, Mo. U.S. Pat. 932,161, Aug. 24, 1909.

THE apparatus comprises a chamber provided with two rotatable electrodes having circular contacting surfaces, and forming the terminals of an electric circuit. The contacting surface of one electrode is in the form of a complete circle, whilst the surface of the second is formed of two separate segments of a circle, so that as the latter rotated, it turns the circular electrode, and the circuit alternately closed and opened, with the intermediate reduction of arcs. Means are provided for holding the circular electrode in yielding relation to the contacts "the first electrode," and "for adjusting the pressure between the electrodes," whereby good contact is secured between the two surfaces. A blast of air is delivered in proximity to the electrodes, and the gases produced are led off through a suitable exit.—B. N.

urnace; Electric —. F. J. Tone, Niagara Falls, N.Y. U.S. Pat. 932,069, Aug. 24, 1909.

THE furnace has an arc reduction zone, and a receiving space below for the collection of the molten products, the two parts being separated by a hearth. The latter supports, and is practically impervious to, the charge, but is pervious to the molten products of reduction. The lower electrode consists of a resistance column, extending through the receiving space, and is adapted to heat the products of reduction.—B. N.

urnace; Electric —. G. C. Landis, York, Pa., Assignor to American Phosphorus Co., Camden, N.J. U.S. Pat. 932,296, Aug. 24, 1909.

THE furnace comprises a casing provided with a non-conducting lining, within which is a carbon lining forming working chamber. The casing is provided with two necks, the carbon lining extending into each neck. An inclined tapping opening extends laterally from the bottom of the working chamber through one of the necks, means being provided for closing the opening. A carbon terminal is embedded in the carbon lining, extending under the working chamber and laterally through the second neck of the casing, thus connecting it electrically to the carbon lining. A second electrode is supported within the chamber.—B. N.

urnace; Electric —. F. M. Becket, Niagara Falls, N.Y., Assignor to Electro Metallurgical Co., West Virginia. U.S. Pat. 932,368, Aug. 24, 1909.

THE furnace comprises a working chamber, with metallic electrodes extending into the same, and cooling jackets applied to the electrodes. The cooling jackets are adjusted longitudinally, for the purpose of regulating the cooling effect at the working ends of the electrodes.—B. N.

etrical resistances, fire-proof bodies, and constructional work; Composition applicable for use in —. W. A. Phillips, St. Louis, and F. R. Bacon, Milwaukee, U.S.A. Eng. Pat. 17,340, Aug. 18, 1908.

Iron; Pure electrolytic —. Z. Elektrochem., 1909, 15, 595—596.

THE Langbein-Pfanhauser-Werke Aktiengesellschaft of Leipzig is now producing on a commercial scale, plates and other articles of iron of at least 99.95 per cent. purity. The process which yields this pure iron is due to F. Fischer, and the iron is obtained electrolytically in a single operation, direct from the electrolytic bath, using merchant iron as anode. As would be expected, this iron is of quite extraordinary softness and ductility, and its electrical properties are just what experience of other irons of great purity and softness would lead one to predict. Its hardness, as measured by Brinell's method, is 92 before and 62 after annealing. On the same scale the hardness of steel is 300—500, of annealed copper 95, of gold 97, silver 91, and aluminium 52, so that the hardness of this electrolytic iron is far below that of pure silver and gold, and near to that of aluminium. On rolling out a $\frac{3}{16}$ -in. plate to one-fifth of that thickness the hardness rises to 175, but falls again to 60—62 on re-annealing. The iron is easily worked, can be cut with a knife or hammered out cold, and is easily welded. Articles shaped of it by the smith can be hardened throughout or only in parts and to any desired extent by making the parts to be hardened take up carbon from any of the usual hardening materials. Plates are at present being manufactured of all thicknesses from $\frac{1}{8}$ to $\frac{3}{16}$ -in. These plates appear to be specially adapted for the preparation of stereotypes, as the printing surface may be given any degree of hardness, whilst the ductility of the backing may be retained. Thin seamless tubes up to 1 inch are also being made, and one of the most interesting products of the factory is an armoured lead pipe of this diameter wholly encased in iron of 1 mm. thickness. It is said that the factory will shortly be turning out articles of almost all sizes and shapes, and at prices which will enable them to compete with existing manufactures quite apart from their properties, which would secure them the preference for special purposes.

Nickel; Electrochemical behaviour of —. A. Schweitzer. Z. Elektrochem., 1909, 15, 602—610.

FOERSTER (see this J., 1907, 643, 1014) has stated that the electrolytic separation of iron and nickel from solutions of their simple salts is retarded in a manner similar to that which has frequently been observed in the separation of metals from complex salts. Experiments by Mustad (Dissertation, Dresden, 1908) showed that in the case of iron, the cathode potential necessary for the separation of the metal at the ordinary temperature was considerably higher than the equilibrium-potential of iron as determined by Richards and Behr (this J., 1907, 326) and that it varied considerably with the current density used:

the variation of the separation-potential from the equilibrium-potential and its alteration with change of current density were less marked as the temperature was increased. The author has now made similar experiments with nickel in nickel chloride solution containing 0.5 per cent. of boric acid and in nickel sulphate solution containing sodium acetate in addition to boric acid. Just as in the case of iron, it was found that the potential necessary for the separation of the nickel rose with increase of the current density, and that the differences were less marked as the temperature was increased. For example, in nickel chloride solution, the separation-potentials (e_h) observed, with current-densities of $22 \cdot 10^{-4}$ and $182 \cdot 10^{-4}$ ampère per sq. cm. respectively, were:—at 16°C , 0.563 and 0.693 volt; at 52°C , 0.384 and 0.475 volt; at 75°C , 0.281 and 0.345 volt; and at 95°C , 0.241 and 0.275 volt. Conductivity measurements indicated that the high potential required for the separation of the nickel is not due to the formation of complex salts. The anodic (electrolytic solution) potential of nickel is affected even more strongly than the cathodic (electrolytic separation) potential by change of current density. Attempts to determine the equilibrium potential of nickel did not give conclusive results, but the values obtained, when taken in conjunction with those of Schoch (Amer. Chem. J., **41**, [3], 240) indicate that in $N/1$ nickel sulphate solution, the equilibrium-potential (e_h) of nickel lies between 0.20 and 0.33 volt.—A. S.

PATENTS.

Metals; Electro-deposition of —. J. J. N. Brachmann, Paris. Eng. Pat. 23,193, Oct. 30, 1908.

THE process relates to the electrolytic "metallisation" of articles which will not withstand the temperature of melted wax. The objects are first coated or impregnated by "steeping or injection with a mixture of ceresine (purified mineral wax), and paraffin or other analogous products, ordinarily derived from petroleum, lignite or other bituminous schists, dissolved in a suitable solvent." They are then covered with plumbago, to render the objects conductors of electricity, and the required metal is deposited directly on the articles, without an intermediate deposit of copper or the like.—B. N.

Metals; Electrolytic deposition of —. F. C. Mathers, Bloomington, Ind. U.S. Pat. 931,944, Aug. 21, 1909.

THE metal, or an alloy of the metal, is subjected as anode to an electric current, in a solution containing a perchlorate of the metal and free perchloric acid, the metal contained in the salt being deposited upon the cathode.—B. N.

Metals; Process for the electro-deposition of — by wet processes, dispensing with the preliminary scouring of the objects. A. Levy. Second Addition, dated Feb. 20, 1909, to Fr. Pat. 385,058, Feb. 25, 1907 (this J., 1908, 818 and 948).

THE deposition of metal is stopped, and the bath is transformed into a scouring bath with a soluble anode, by adding a quantity of a cyanide to the materials employed as the electrolyte described in the main patent.—B. N.

Ores [of refractory metals]; Method of reducing —. F. M. Rockett, Niagara Falls, N.Y. U.S. Pats. 930,027 and 930,028, Aug. 3, 1909.

THE ore is smelted in an electric furnace with a reducing agent containing silicon and boron, which are present in the necessary proportions to combine with the oxygen of the ore, whereby a metal or alloy, low in silicon and boron, is obtained. Or the ore is smelted with a boride, such as calcium boride, in an electric furnace, which is maintained at a temperature sufficient to practically eliminate boron from the reduced product, the slag being subsequently treated to recover the boron.—F. R.

[Copper] Ores; Process of treating —. P. L. T. Héroult, La Paz, France, Assignor to Soc. Electro-Metallurgique Française, Froges, France. U.S. Pat. 930,666, Aug. 10, 1909.

THE sulphide ore is fed into an electric arc furnace and gradually passed through a zone of fusion adjacent to

the arc. Sufficient oxygen or air is simultaneously injected into the ore, above the zone of fusion, to oxidise a large part of the sulphur and iron and leave only a black copper melt, with a slag consisting of iron and gangue.—F. R.

Magnesium; Electrolytic production of —. G. O. Seward and F. von Kugelgen, Holcombs Rock, Va., Assignors to Virginia Laboratory Co., New York. U.S. Pat. 931,092, Aug. 17, 1909.

TO a bath of magnesium chloride, in a state of fusion, an alkaline-earth chloride is added to increase its density, so that the electrolytically separated magnesium may float to the surface. Barium chloride or a mixture of barium and potassium chlorides is suitable for the purpose.—I. W. H.

Nickel and nickel alloys; Process for obtaining — from the natural nickeliferous iron-magnesium hydrosilicates known as garnierite. M. A. J. Roux and Soc. Le Nickel de la Nouvelle-Calédonie. Fr. Pat. 399,412, April 21, 1908.

GARNIERITE is first reduced by fusion with calcium carbide in an electric furnace. The powdered garnierite may be added to previously fused carbide, or the two substances, which may be agglomerated into briquettes, are fused together. If necessary, silicon, ferro-silicon, or boron, is added, so as to prevent the formation of metallic carbides. The melt obtained, which consists of silicides of nickel, iron, etc., together with metallic nickel, is then subjected to an oxidising process in the same or in a second electrical furnace. Air or oxygen is blown through the melt, to which peroxides of manganese, barium or calcium may also be added. The process is stopped when only nickel remains unoxidised.—A. G. L.

Metallic solutions; Electrolysis of — with insoluble anodes, and cathodes animated by a movement of displacement. F. Lacroix. Fr. Pat. 400,262, Feb. 26, 1909.

THE invention relates to the electrolysis of metallic solutions, particularly impure solutions, poor in copper, derived from ores containing iron. Insoluble anodes, preferably perforated, are employed, and are surrounded by convenient cylindrical cathodes, the latter or both electrodes being maintained in movement. Intense currents may thus be employed, yielding coherent and regular deposits. The deposits are produced with sufficient rapidity to practically suppress the solvent action of the iron salts on them, thus leaving these salts free to assist in the solution of the metal contained in the ore. Local currents between different parts of the cathode are also entirely suppressed by employing concentric electrodes.—B. N.

Electrolytic galvanising process. C. Bianco, Turin, Italy. Eng. Pat. 15,931, July 15, 1908.

—C. A. M.

Wax of the sugar cane and its technical isolation. A. Wijnberg. Dissertation, Amsterdam, 1909. Deutsche Zuckerind., 1909, 34, 629—630.

In the working-up of the sugar-cane by the ordinary lime-defecation process, a considerable quantity (1 per cent. and more on the weight of the cane) of "mud" is obtained, which at the present time has little or no value. The author has found that this mud contains a relatively large proportion (10—12 per cent. on the dry substance) of the so-called "cane-wax." The nature and colour of the wax vary considerably with the variety and cultural conditions of the sugar cane. From 5000 kilos. of the fresh mud produced in Java, there was obtained by extraction with benzene, a considerable quantity of the crude wax, which proved to be a complex mixture of different substances. About 70 per cent. of the crude wax consisted of fats (glycerides of oleic, linolic, palmitic and stearic acids), together with hydroxy-acids, resin-acids, lecithin, phytosterol, and aromatic and colouring matters. The remaining 30 per cent. consisted of a wax-like substance, apparently identical with that obtained by scraping the bark of the sugar-cane. It was, however, not an individual substance, as stated by earlier workers. It contained about 45 per cent. of myricylalcohol, about 35 per cent. of a non-primary, crystalline alcohol, $C_{33}H_{65}O$, and also at least one crystalline substance, poorer in oxygen, almost insoluble in hot alcohol, and of high melting point (88° — 90° C.). In the sugar factories it is the practice to store the mud in heaps. Under these conditions, a kind of fermentation takes place, the fatty substances being almost completely decomposed, whilst the more resistant wax-like substance remains more or less unaffected. From the "fermented" mud the wax can be isolated by re-crystallisation from petroleum spirit. It is best refined by dissolving in petroleum spirit and treating with fuller's earth or similar material. In this way, a white or pale yellow wax is obtained which resembles carnauba wax in its hardness, appearance, and high melting point (82° — 88° C.). For the technical preparation of the wax, the "fermented" mud is dried, first in the sun and finally by waste smoke gases or in a Huillard furnace, then broken up, and extracted with benzene. The residual mud, after extraction, is still available as a manure, and may also be treated for the extraction of the sugar contained in it. (See also Fr. Pat. 397,843; this J., 1909, 899.)—A. S.

Carnauba wax; Saponification of — R. Berg. Chem.-Zeit., 1909, 33, 885—887.

THE author points out that, in determining the saponification value of carnauba and other waxes which are markedly resistant to saponification, all the methods which have been suggested to accelerate and complete the saponification introduce errors into the test. In employing sodium alcoholate (Kossel and Obermüller) the products of saponification are not attacked, but saponification is not complete. Complete saponification is arrived at by using an alcohol of high boiling point as the solvent, as suggested by Einhorn and later used on carnauba wax by Radcliffe (this J., 1906, 158). The method is open to the serious objection, however, that during the six hours' heating which is necessary, the alkali acts upon the alcohol in a manner which is so irregular as not to be controllable by a blank experiment. Following the lines of the method suggested by Marcusson for saponifying

montan wax, in which benzene is used as the solvent, the author works as follows, replacing the benzene by xylene. To 4 gms. of wax dissolved in 20 c.c. of xylene, 50 c.c. of $N/2$ alcoholic potash are added, the acid value being determined in the usual way during the addition of the alkali. The flask is fitted with a reflux condenser and heated for two hours on a vigorously boiling water-bath, which results in complete saponification being effected. The soap which is produced separates in part, and to dissolve this, 100 c.c. or more of alcohol are added until a clear solution is obtained, when titration is proceeded with in the usual way. In the exceptional case of saponification not being complete after heating on the water-bath, a few minutes' boiling on a wire gauze over a flame, with or without the further addition of xylene, as may be considered necessary, is sufficient to complete the reaction.

—J. A.

Montan wax; Composition of — K. Eisenreich. Chem. Rev. Fett- u. Harz-Ind., 1909, 16, 211—213.

THE commercial sample of Schliemann's purified montan wax examined by the author melted at 77° C., and gave the following analytical values:—Acid value, 93.02; saponification value, 94.56; iodine value, 12.00; acetyl acid value, 93.01; acetyl value, 11.18, and unsaponifiable matter, 29.07 per cent. Assuming that no other acid was present, the acid value corresponded to 72.66 per cent. of free montanic acid in the wax. By repeated recrystallisation from petroleum spirit and ethyl acetate, a pure white montanic acid (m. pt. 82.5° C.) was obtained. This was separated by fractional precipitation with magnesium acetate from an alcoholic solution into six fractions, the first four of which melted at 83° C., the fifth at 82.5° C., and the residue at 81.5° C. Elementary analyses of the fractions and other methods are said to give results agreeing with Hell's formula for montanic acid, $C_{29}H_{58}O_2$. The unsaponifiable matter had a composition corresponding to the formula, $C_{42}H_{86}O$, but no alcoholic hydroxyl group could be identified in it (see also this J., 1909, 894).—C. A. M.

Grease from sewage sludge. Bechhold and Voss. See XVIII.B.

"Hydrocarbons with acid functions" [from petroleum]; Use of — as substitutes for fatty acids, oils, fats, and soaps. C. M. D. Bazin. Fr. Pat. 399,212, April 15, 1908.

It is stated that the "hydrocarbons with acid functions" obtained by treating petroleum with alkali and acidifying the resulting alkaline tar, may be used as substitutes for fatty acids for all technical purposes. Claim is also made for the use of amides, esters and salts of these acids for the same purpose. The acids form soluble soaps with alkalis, and give insoluble salts with alkaline-earth bases (notably alumina). As the latter do not become soft below 120° C. they can be advantageously used in the preparation of solid fats for sizing textile fabrics, etc.—C. A. M.

Fat; Process of extracting — from agricultural and industrial substances, and manufacture of the solvent used in the process. A. Guétan and H. Simenin. Fr. Pat. 400,105, May 20, 1908.

HOT or cold neutralised solutions of sulphonated liquid fatty acids are used for the extraction of fat both in the free state and in the form of calcium or aluminium soaps, etc., from industrial organic substances, such as bone, hides, etc. The solvent may be prepared by treating 10 parts of liquid fatty acids with 1 part of sulphuric acid (65° B.), agitating the mixture for 4 hours, decanting the sulphonated product, washing it with salt water, and neutralising it at a low temperature with a solution of caustic soda.—C. A. M.

Soap or other washing material: Manufacture of pulverised —, O. Lindemann, London. From Gebrüder Körting A. G., Lünden, Germany. Eng. Pat. 26,133, Dec. 3, 1908.

A DRIER soap powder than that made according to the process described in Eng. Pat. 25,276 of 1907 (this J., 1908, 345) may be prepared by forcing the liquid soap from a container through a pulverising apparatus and mixing it with superheated steam or highly heated air or gas as it escapes from the pulverising nozzle. The steam under a pressure of 1 or 2 atmospheres and at a temperature of about 300° C. issues from a chamber surrounding the nozzle. —W. P. S.

Soap or soap compound [for making cotton non-inflammable.] J. V. J. Hollingworth, Ashton-under-Lyne. Eng. Pat. 717, Jan. 12, 1909.

A SOAP to render cotton fabrics non-inflammable after washing is prepared by mixing a dry powdered soap (say, 180 parts) with sodium silicate (24 parts), and adding oleic acid previously saponified or made into a dry paste with potassium carbonate (8 parts), glycerin (7 parts) and sodium tungstate (4 parts). —C. A. M.

Soaps of every kind: Apparatus and process for making —, L. Rivière. Third Addition, dated Feb. 18, 1909, to Fr. Pat. 374,179, Jan. 12, 1907 (see this J., 1907, 769, 881; 1909, 317).

CLAIM is made for the use of sodium bisulphate (preferably that obtained as a by-product in the manufacture of nitric acid) for the liberation of fatty acids from insoluble and other soaps. It is stated that the fatty acids have a higher melting point and less colour than those liberated by a mineral acid. —C. A. M.

(I.)—PIGMENTS, PAINTS.

PATENTS.

Red lead, and apparatus for its manufacture. G. V. Barton, Runcorn. Eng. Pats. 13,458, June 24, 1908, 24,242, Nov. 11, 1908, and 26,259, Dec. 4, 1908.

MOLTEN metallic lead is converted into lead oxide by treatment with a blast of air and steam and continual stirring as described in Eng. Pat. 4660 of 1902 (this J., 1903, 150). To effect complete oxidation of the lead, the fumes from the furnace are carried to a sufficient height in a shaft of metal or other conducting material, which is kept at a red heat by gas flames or otherwise. The resulting lead oxide is free from metallic lead and is in such an extremely fine state of division that when converted into red lead it gives a product of greater brilliancy than can be obtained from ordinary litharge. The lead oxide furnace may be connected with a series of red-lead furnaces by means of branches radiating from the top of the shaft and each controlled by a valve, so that each red-lead furnace may be fed in succession. —C. A. M.

Coatings [for wood, metals, etc.]; Manufacture of fireproof and waterproof —, A. Levy, Amsterdam. Eng. Pat. 15,339, July 20, 1908.

MAGNESITE is calcined at a temperature of from 590° C. to 600° C., and to 100 parts of the calcined product are added 15 to 30 parts of dry magnesium chloride, 50 parts of calcium carbonate (powdered marble, chalk, etc.) and a pigment, preferably of mineral nature. The ingredients are thoroughly incorporated, and are mixed with the requisite quantity of water when required for use as fireproof and waterproof coating. If 10 to 20 parts of paper pulp, or cellulose, tramic fibre, etc., are added to the mixture, a product is obtained, which is especially suitable for decorating wall paper, cardboard, and the like. —O. R.

White lead; Process for making —, J. A. Erhslow, Los Angeles, Cal. U.S. Pat. 930,057, Aug. 3, 1909.

METALLIC lead in a fine state of division is made to pass alternately from a body of water to an atmosphere containing oxygen and carbon dioxide, the corrosion and attrition of the particles causing a scum of white lead to form upon the surface of the liquid. This scum is subsequently drawn off by suction, or otherwise, and dried. —C. A. M.

Ultramarine; Apparatus for the manufacture of artificial —, J. Luciani and V. Battesti. Fr. Pat. 399,211, April 15, 1908.

THE oxidising agents used in the manufacture of artificial ultramarine are placed in a perforated tube, which is then introduced into the centre of the cylinder containing the substances to be oxidised. The oxygen liberated by the heat from the stove surrounding the cylinder passes through the holes and effects rapid and uniform oxidation, so that the formation of gray products is completely prevented. The end of the perforated tube may also be connected with a supply of compressed oxygen, which may thus be made to permeate the mass at the required moment. —C. A. M.

Ultramarine; Process and apparatus for the manufacture of artificial —, J. Luciani. Fr. Pat. 400,103, May 19, 1908.

THE raw materials are heated together in such a way that heat is applied both at the centre and the outside of the mass, which is subsequently oxidised at the required moment by means of air introduced through longitudinal tubes. In the type of apparatus claimed, the reaction-vessel is conveniently constructed in the form of concentric cylinders, and the material is introduced into the space between the two walls. The gases of the furnace can thus pass through the central open space as well as over the exterior of the vessel. The end of the vessel is closed by a partition perforated with large openings for the introduction of the air tubes and with small openings for the escape of the gaseous products, and over this is fixed a cover which can be removed at the required moment for the oxidation. —C. A. M.

Printing inks and oil paints; Manufacture of —, F. G. Jagenburg. Fr. Pat. 399,604, Feb. 18, 1909. Under Int. Conv., Feb. 19, 1908.

AN aqueous solution of a dyestuff is incorporated with a thickening agent, composed of thickening substances (such as dry kaolin or hydrated aluminium silicate) and an oil (e.g. boiled linseed oil) or resin or resinous solution, or mixtures of these. Barium chloride or an analogous substance is then added, and the resulting precipitate (freed from water if desired) incorporated with a sicative. The process may be varied by adding the thickening agent to the precipitated pigment. Insoluble dyestuffs are first made into a paste with water and ground up with the thickening agent until the excess of water separates. Similarly, commercial pigments in the form of a slightly soluble paste are heated with water to the boiling point, and the thickening agent added to the liquid after cooling; after which the process is continued as described above.

—C. A. M.

Pigments; Method of increasing the technical effect of the means used to render — opaque, and of increasing the effect of filling materials for inflammable substances. G. Galy. Fr. Pat. 400,285, March 4, 1909.

THE wood flour or cork dust, etc., used for the purposes mentioned, is thoroughly incorporated by means of milling, etc., into a homogeneous mass, which may then be subjected to further treatment. Thus after the addition of fusible material (sulphur, celluloid) at a temperature lower than the ignition point of the wood, cork, etc., the mixture may be melted, cooled, reduced to fragments, and, if desired, again finely ground.—C. A. M.

Lead salts or oxides [red lead]; Process and apparatus for making —. G. V. Barton. Fr. Pat. 400,279, March 1, 1909.

SEE Eng. Pat. 13,458 of 1908; preceding.—T. F. B.

Azo dyestuff for manufacture of lakes. Fr. Pat. 399,132. See IV.

(B.)—RESINS, VARNISHES.

*Burmese varnish [sap of *Melanorrhæa Usitata*]; A chemical investigation of the constituents of —.* P. Sing. Indian Forest Records, 1909, 1, [IV.], 287—308.

BURMESE varnish is obtained from a deciduous tree, *Melanorrhæa Usitata* (Burmese, *thitsi*), occurring abundantly in Burma and Siam. The tree is closely allied to the Japanese lacquer tree, *Rhus vernicifera* (Japanese, *Urushi-noki*), and belongs to the same natural order, *Anacardiaceæ*. The sap is obtained by making a V-shaped incision in the stem and placing a bamboo cup to receive it. After 10 days, the flow of sap being very slow, the cup is emptied. The crude varnish obtained is purified by straining through coarse cotton cloth. Burmese varnish sets hard only in a cool moist atmosphere; it will not set by the action of heat, sunlight, or a dry atmosphere. It is a thick greyish fluid which on exposure to the air becomes first brown and finally jet black. The sp. gr. at 20° C. of a pure sample was 1.0016 (sp. gr. of pure Japanese lacquer at 20° C. = 1.0020). The method of chemical investigation was based on that used by Ishimatsu and also by Yoshida, when examining Japanese lacquer. A resinous extract (A) was made by treating the strained varnish with hot alcohol, and dried at 105° C. The residue was treated with dry ether and the extract dried and treated with hot alcohol, when a small quantity of fatty matter was obtained as residue, together with a further small quantity of resinous extract which was added to (A). The main residue was treated with water and the solution obtained diluted with more water and boiled, when a brownish precipitate (indicating albuminous matter) separated out and was filtered off. The filtrate containing the gummy constituents (B) was evaporated and dried until its weight was constant. The residue (C) which was insoluble in both hot alcohol and boiling water was dried at 100° C.

Examination of the constituents A, B, and C showed that the principal constituent of Burmese varnish is urushic acid ($C_{14}H_{18}O_2$), and that this and the other chief constituents are identical with those of Japanese lacquer.

Comparative analyses.	Burmese varnish.		Japanese lacquer.	
	I.	II.	I.	II.
A. Alcoholic extract (urushic acid)	86.24	83.24	85.15	80.00
B. Gummy matter	3.08	3.52	3.15	4.69
Oil matter	nil.	.53	?	?
C. Residue or diastatic matter	1.71	2.14	2.28	3.31
Moisture and other volatile matter	8.97	10.57	9.42	12.00
	100.00	100.00	100.00	100.00

The principles and conditions of use of Burmese and Japanese varnishes being the same, the author makes a number of suggestions for improving the Burmese lacquer

industry. Since rust attacks urushic acid, iron tools and vessels should be avoided or kept scrupulously clean. In collecting the sap, care should be taken to exclude dust. From Japanese practice it is known that the sap from the lower parts of a tree is the finest, and it would be better to collect it and use it separately for finishing coats. An inferior varnish can also be obtained from the branches of a felled tree by placing them partly in hot water and making incisions in their upper third parts which are out of the water. The juice before storing should be thoroughly stirred in shallow pans, to get rid of any volatile poisonous matter and to produce greater homogeneity. The air of the drying cellar should be kept moist by means of wet cloths. Sesame oil which is often added to Burmese varnish should be avoided and linseed oil used in its place.

With a natural varnish as fine as that of Japan, there seems no reason why the lacquer industry of Burma should not develop to a degree like that of Japan. (See this J., 1889, 906; 1894, 1071).—J. W. H.

Turpentine and rosin in the United States. Board of Trade J., Sept. 9, 1909. [T.R.]

A REPORT on the timber supply of the United States, issued by the Department of Agriculture, states that the production of naval stores in 1908 included more than 36 million gallons of turpentine and more than four million barrels of rosin, of which Florida and Georgia supplied two-thirds. About one-half of the product is exported. While the production of naval stores does not necessarily destroy the forests, the methods so far used, coupled with subsequent fires and wind storms, have resulted in the destruction of a great deal of saw timber.

PATENTS.

Wood; Method of treating — during distillation. H. W. Doughty, Amherst, Mass., Assignor to F. E. Waters, Baltimore, Md. U.S. Pat. 930,274, Aug. 3, 1909.

THE wood is pulped and the cellulose is hydrolysed by adding sulphuric acid to the retort during the heating to drive off the volatile oils. The acid solution is separated and the solid residue is treated with sodium hydroxide solution. The alkaline liquor obtained is filtered off and mixed with the acid solution obtained before, whereby the resinous acids are precipitated. The clear liquor is withdrawn and fermented, the alcohol produced being afterwards distilled off.—W. H. C.

Turpentine oil; Process for the manufacture of synthetic —. A. Poulverel. Fr. Pat. 400,180, May 23, 1908.

ROSIN oil is introduced gradually into a closed horizontal narrow tubular retort, charged with soda-lime and heated to about 400° C. After about 5—6 minutes, the retort is connected to a condenser and the products condensed. The distillate thus obtained is washed with concentrated sulphuric acid, then with caustic alkali, and afterwards with water. It is next treated with 0.5 per cent. of caustic soda lye or 3—5 per cent. of lime water, and distilled with steam. The product thus obtained is said to possess the same chemical and physical properties as natural turpentine oil.—A. S.

Dipping varnishes possessing covering power; Process for the preparation of —. H. Zwick. Ger. Pat. 211,573, May 26, 1907. Addition to Ger. Pat. 211,529, Feb. 10, 1907.

INSTEAD of the nitrocellulose used according to the main patent (see this J., 1909, 843), the cellulose esters of aliphatic acids, alone or mixed with nitrocellulose, are employed.—A. S.

(C.)—INDIA-RUBBER, &c.

Rubber from Southern India. Bull. Imp. Inst., 1909, 7, 163—166.

FIVE samples of rubber prepared from Ceara, Castilloa, and Para trees growing in the Government Experimental Gardens at Kullar and Burlar in the Nilgiri Hills, were examined. The results of the chemical examination,

and the commercial values (fine hard Para at 5s. 1d. per lb. and plantation Para biscuits at 5s. 3d.—5s. 9d. per lb.) are shown in the following table:—

	I.	II.	III.	IV.	V.
	per cent.	per cent.	per cent.	per cent.	per cent.
Moisture	2.8	1.5	0.2	0.8	0.4
Caoutchouc	80.2	62.7	86.1	92.0	91.5
Resin	6.2	32.0	12.8	2.6	3.9
Protein	9.5	0.9	0.5	3.0	3.7
Ash	1.3	2.29	0.4	1.6	0.5
Value, per lb. . .	5s. 6d.	3s. 2d.— 3s. 4d.	3s. 6d.— 3s. 8d.	5s.— 5s. 2d.	5s. 4d.— 5s. 5d.

Sample I. was Ceara rubber in the form of six biscuits of pale amber-coloured rubber of very good quality; it contained 76.5 per cent. of "soluble" and 6 per cent. of "insoluble" caoutchouc, reckoned on the dry rubber. No. II. was a rough sheet of dark brown Castilla rubber of inferior quality. No. III. consisted of rough sheets of Castilla rubber, varying in colour from light to dark brown. No. IV. consisted of biscuits of dark brown Para (*Hevea brasiliensis*) rubber, rather deficient in strength; it contained 88.8 per cent. of "soluble" and 4 per cent. of "insoluble" caoutchouc, reckoned on the dry rubber. No. V. consisted of two biscuits and three strips of Para rubber, rather uneven in colour, and of fair strength; it contained 90 per cent. of "soluble" and 1.9 per cent. of "insoluble" caoutchouc, reckoned on the dry rubber.—A. S.

Rubber; Direct determination of — in soft-rubber goods.
S. Axelrod. Chem.-Zeit., 1909, 33, 895.

IN replying to criticisms passed by Hinrichsen and others (this J., 1909, 843) upon his method for the direct determination of rubber in samples of hot-vulcanised rubber (this J., 1907, 1058), the author points out that his process was not designed to meet the case of hard rubber. Hence the error introduced by using the same factor, 314, for all cases can only be a small one, since the vulcanisation-coefficient of soft-rubber generally lies between 2.3 and 3 per cent., and, in an extreme case, if the coefficient were 4.4 per cent., the error due to this cause would only be 1.5 per cent. It is claimed that methods involving the use of a dried, weighed filter are quite usual in analytical practice, and easily carried out. Hydrobromic acid is not split off from the bromide if the drying be conducted at temperatures not exceeding 60° C. With the exception of the silicates the mineral matter in a vulcanised rubber sample is converted into bromides of the respective metals by the action of the bromine solution used, and the bromides are soluble in alcohol. Hence it is quite allowable to estimate the weight of actual vulcanised rubber bromide present in the precipitate from the bromine treatment, by subtracting from the total weight of the precipitate the weight of its ash. An exception occurs in the presence of lead, lead bromide not being soluble in the washing liquid. The appropriate treatment in this case is to moisten the bromide precipitate with sulphuric acid and a few drops of nitric acid, subsequently driving off the excess of acids and igniting. The error introduced by deducting the weight of lead sulphate thus obtained from the weight of the crude bromide is very small, seeing that litharge is rarely present in amounts exceeding 15 per cent. in rubber mixings. The error may, of course, be avoided altogether by estimating the lead oxide present. The author contends that the analytical error in the case of a mixing containing a maximum percentage of litharge, and having a vulcanisation coefficient as high as 4.5 per cent., is, by his method, as low as 3.48 per cent.—E. W. L.

Rubber goods; Analysis of —. F. Frank and E. Marckwald. Gummi-Zeit., 1909, 23, 1522—1524.

AXELROD'S tetrabromide method (this J., 1907, 1058) for the determination of rubber in rubber goods is subject, in certain cases, to errors as great as 10 per cent. This is not due, however, as stated by Hinrichsen (this J., 1909, 843) to the presence of mineral matter, but, as

pointed out by Harries and Rimpel (this J., 1909, 945), to the fact that a portion of the rubber, as bromine derivative, passes into solution in the mixed solvents employed. The authors criticise the method proposed by Hinrichsen (*loc. cit.*) for the determination of mineral matters. Employing three very different, typical mixings, they find that, working according to Hinrichsen's directions, the following difficulties are encountered:—(1), the organic matter is not completely dissolved, and some is held back on the filter with the mineral matter; (2), certain mineral constituents are partially or completely decomposed at the high temperatures employed, magnesium carbonate losing combined water and carbon dioxide, and golden sulphide (pentasulphide) of antimony being converted into trisulphide by loss of sulphur; (3), the solution of the vulcanised rubber in petroleum, when diluted with benzol, is exceedingly slow in clarifying by settling, and it is very difficult, sometimes impossible, to obtain a clear filtrate. By modifying the method in some of its details, the authors find it is possible to make it useful in cases where the method of dissolving in xylol in an autoclave (see this J., 1908, 989) is not available. They proceed as follows:—

The finely cut-up rubber sample is heated with heavy petroleum (b. pt. 230°—260° C.), or with paraffin oil of sp. gr. 0.86, for from 15 to 60 minutes. The solution is allowed to cool, and is then diluted with petroleum ether or light benzine, but not with benzol. Such diluted solutions are found to clarify in from two to ten hours. The solution is then filtered and the residue on the filter washed with the solvent used for dilution, dried, and weighed. The flask in which the solution was effected is also washed, dried, and weighed, to allow for any mineral matter not transferred to the filter. If antimony be present, the residue is washed first with ammonium sulphide, and the antimony estimated by difference, then with hot, dilute hydrochloric acid to remove all acid-soluble minerals, which are also estimated by difference. The final residue is ignited, and weighed again; the difference in weight obtained represents carbon black and organic matter not otherwise accounted for.—E. W. L.

Rubber crop of the Amazon Valley. Board of Trade J., Sept. 2, 1909. [T.R.]

THE following are the statistics of the rubber crops in the Amazon Valley for the seasons 1907-8 and 1908-9:—

	1907-8.		1908-9.	
	Rubber.	Caucho.	Rubber.	Caucho.
	metric tons.	metric tons.	metric tons.	metric tons.
Islands	8,346	—	8,944	—
Itaituba and Lower Amazon	1,199	126	1,542	275
Tocantins, Xingu, and Jary	—	679	—	729
Beni	867	227	1,045	488
Juruá	1,043	132	1,034	158
Purus	3,467	660	3,531	827
Manaos and Itacoatiara ..	13,336	4,154	13,031	4,204
Iquitos	1,540	964	935	1,327
Total	29,708	6,942	30,062	8,008
Grand total, rubber and caucho	36,650		38,070	

Rubber cultivation in the Malay Peninsula. Board of Trade J., Sept. 9, 1909. [T.R.]

THE progress of rubber cultivation in the Malay Peninsula continues to be rapid and successful. At the end of 1908 there were 37,440,020 trees, as compared with 27,558,440 a year before; 60,636 acres were planted during 1908, an increase of over 33 per cent. on the previous year, giving a total of 241,138 acres of rubber on the 31st December for the whole Peninsula. The output of dry rubber increased in 1908 by 56 per cent.; 3,539,922 lb., or 1,580 tons, being produced as against 2,278,870 lb., or 1,017 tons, in 1907. This was sold at an average price of about 4s. per lb.

The following figures show the amount of cultivated rubber exported from the Federated Malay States during the first six months of the years 1908 and 1909:—

	January—June, 1908.	January—June, 1909.
	lb.	lb.
Perak	189,633	364,890
Selangor	866,567	1,657,104
Negri Sembilan	325,958	441,247
Malacca	nil	nil
	1,382,158	2,463,241

Of the rubber exported from Selangor during the first six months of 1909, 25,030 lb. were produced in Perak and 177,522 lb. in Negri Sembilan.

PATENTS.

Rubber-like gum from its vegetable sources; Process of extracting — F. H. Hunkle, Roselle, N.J., Assignor to Continental Rubber Co., New Jersey. U.S. Pats. 931,120 and 931,121, Aug. 17, 1909.

1). THE vegetable matter is mechanically divided, immersed in fresh water until the woody fibre sinks, and the floating gum and bark removed and immersed in a fresh quantity of water until the bark sinks. The gum is then removed and consolidated. (2). The vegetable matter is softened by the action of steam, then mechanically divided, and immersed in water and subjected to the action of a series of hard-surfaced bodies moving independently in the water. The disintegrated material is left in the water until the heavier impurities settle, whereupon the floating gum is removed, subjected to the action of superheated steam under pressure, then compressed, and finally kneaded in presence of water in motion.—A. S.

Resins and gums; Manufacture of substitutes for — by the condensation of aldehydes and phenols. L. Helmi. First Addition, dated April 13, 1908, to Fr. Pat. 392,395, Sept. 23, 1907. (See Eng. Pat. 25,216, Nov. 13, 1907; this J., 1908, 412.)

CLAIM is made for the use of the salt of an amine (aniline hydrochloride or other aniline salt) as the condensing agent, and for the use of an acid to accelerate the process and to obtain a hard "resin."—C. A. M.

Para rubber; Manufacture of artificial — J. Blum and W. A. Carpenter. Fr. Pat. 399,345, Jan. 5, 1909.

A VEGETABLE substance, such as peat, is subjected to fermentation and simultaneously or subsequently treated with a reducing agent, so as to obtain a glutinous mass consisting of a hydrocarbon of the formula, $(C_5H_8)_x$. For this purpose the peat may be mixed with water and treated with the enzyme present in imperfectly formed caoutchouc or with an enzyme that will produce alcohols of a series higher than the olefine series, the fermentation being carried out at a temperature of about 60° C. (not exceeding 71° C.). The glutinous mass of hydrocarbon is next heated with water in which is suspended a nitrogenous substance (preferably the red substance resembling seed contained in red Upper Congo rubber), and to which mineral salts have been added, after which the mixture is cooled, and the layer of synthetical Para rubber removed from the surface, and purified by treatment with an alcoholic liquid.—C. A. M.

Caoutchouc; Process for obtaining pure — F. Boegel and A. Kiander. Fr. Pat. 399,459, Feb. 13, 1909.

THE crude material (e.g., inferior qualities of rubber) is freed from impurities by successive treatment with an alkaline solution, with a "hydrated compound of chlorine," and with acetone or formaldehyde.—C. A. M.

Goods of rubber, ebonite, or vulcanite; Method of manufacturing — O. C. Immisch, Finchley. U.S. Pat. 931,310, Aug. 17, 1909.

SEE Eng. Pat. 3659 of 1908; this J., 1909, 374.—T. F. B.

XIV.—TANNING, LEATHER, GLUE, SIZE.

Tannin; Determination of — by electrolytic means. M. Corridi. Collegium, 1909, 281—283.

EXPERIMENTS are recorded with the method of tannin estimation proposed by Metzger (this J., 1908, 458), in which an electric current is passed through the tannin infusion and the tannin thereby precipitated, the non-tannins being then determined by the evaporation of 50 c.c. of the filtrate. The author found that the results obtained by this method do not agree with those by the hide powder method on account of the precipitation by the electric current of gums and other non-tanning substances. He also experienced difficulties in carrying out exactly the precise method proposed by Metzger, especially in obtaining complete precipitation of the tannin in the time specified and also in filtering off the precipitate. Continuous and alternating currents, moreover, were found to yield different results.—H. G. B.

Sulphurous acid in commercial gelatin. W. Lange. Arb. Kais. Gesundh.-Amt, 1909, 32 144—157. Chem. Zentr., 1909, 2, 738—739.

OF 32 samples of gelatin examined, 22 contained quantities of up to 0.125 per cent., and 10 contained more than that quantity of sulphurous acid; the five highest values found were 0.216, 0.219, 0.247, 0.371, and 0.467 per cent. For the determination of the sulphurous acid, 10—20 grms. of the gelatin are swollen in 500 c.c. of water for 15 mins., then warmed until dissolved, and after addition of 2—3 grms. of tannin to prevent foaming, distilled with 20 c.c. of phosphoric acid of sp. gr. 1.15, in a slow current of carbon dioxide; a current of carbon dioxide is also passed through the apparatus before distillation in order to displace the air. From 200 to 250 c.c. of the solution are distilled, and the vapours are collected in a solution of iodine in potassium iodide; after filtering, the sulphuric acid produced by the oxidation of the sulphurous acid in the distillate is determined as barium sulphate. A small quantity of sulphur trioxide is produced in the distillation, which is not derived from the sulphurous acid, and this must be taken into consideration.

Dry gelatin is capable of absorbing 10.1 parts by volume of sulphur dioxide; swollen gelatin contains much less sulphurous acid than does dry gelatin after treatment with sulphur dioxide. The treated gelatin does not evolve sulphur dioxide when exposed to air saturated with aqueous vapour at the ordinary temperature, nor does any oxidation to sulphuric acid take place. The amount of sulphur dioxide is considerably diminished by steeping the gelatin in water, and still more, if the gelatin be immersed in 1 per cent. hydrochloric acid for half an hour before steeping in water. The sulphur dioxide appears to be present in the gelatin in the free state, since on treatment with iodine solution, oxidation to sulphuric acid proceeds continuously to the end, and not in stages as in the case of complex compounds such as acetaldehyde- and dextrose-sulphurous acid (see this J., 1904, 832).—A. S.

PATENTS.

Waterproof leatherboard, and process of preparing the same. E. S. Buffum, Newton, and W. W. Carter, Needham, Mass., U.S.A. Eng. Pat. 9383 of 1909; date of Application, Dec. 28, 1908. Under Int. Conv., Jan. 2, 1908. Addition to Eng. Pat. 28,219 of 1908.

A PULP is prepared containing fibres of tanned leather, with or without fibres of other materials. The chromic and tannic acids present are neutralised by the addition of caustic soda, sodium carbonate, etc., and casein, albumin, or gluten (5—10 per cent.) is then added. After incorporation of the above mixture in the beater for about an hour, a precipitant, such as alum or aluminium sulphate (8—13 per cent.) is added, and the beater run for a further period of about one hour. Should a black material be required, a soluble sulphide is added.—G. W. McD.

Tannage of ungrained hides [sub leather] ; Method of —. Soc. Anon. des Mat. Tannantes et Colorantes. First Addition, dated May 20, 1908, to Fr. Pat. 396,025, Jan. 13, 1908 (this J., 1909, 804).

THE hides are swollen in a formaldehyde bath, tanned with tanning extract in a drum, and after drying more or less completely, given a second tannage in another drum.

—A. S.

Hides and skins ; Means for tanning and depilating —. C. J. Glase, Boston. U.S. Pat. 934,858, Aug. 24, 1909.

PATENT.

Superphosphate reaction chambers ; Process and apparatus for emptying —. K. J. Beskow and M. Ekedahl. Fr. Pat. 399,907, Feb. 25, 1909.

WHEN the reaction is complete, the superphosphate is discharged by means of a series of scrapers or scoops, mounted on a vertical drum or other suitable device, which is rotated and capable of being moved as desired inside the chamber. The scoops attack the heap of superphosphate on the side, and carry the portions detached to the bottom of the chamber, where they are discharged through a suitable outlet.—A. S.

Beet juice ; Occurrence of optically-active non-sugar substances in —. J. Weisberg. Bull. Assoc. Chim. Sucrier, et Dist., 1909, 27, 77—83.

THE author maintains his conclusion that the diminution in the polarisation of beet juice after treatment by Herles' method (this J., 1908, 1168 ; 1909, 32) is not due to the precipitation or destruction by the lime of optically-active non-sugar substances, or to the influence of the large amount of basic lead acetate used (as maintained by Herzfeld and by Blan), but, in the main, at all events, to the precipitation of sugar as sucrate. This is brought about by the addition of the dry lime to the hot juice and subsequent heating of the liquid to the boiling point. The simultaneous addition of a large amount of normal lead acetate (forming with part of the lime a corresponding quantity of basic lead acetate) may also have an influence on the final polarisation, but does not prevent the precipitation of sugar as sucrate. Experiments described show that when the "calco-carbonic" purification of sound juice is properly carried out there is little or no diminution in the polarimetric readings. In the author's opinion the new method of Herles is unsuitable for the determination of sugar in beet-juice or diffusion juice.—C. A. M.

XVII.—BREWING, WINES, SPIRITS, &c.

Yeast ; Poison secreted by —. A. Fernbach. Compt. rend., 1909, 149, 437—439.

THE author has carried out a number of experiments on the yeast-poison discovered by Hayduck (this J., 1909, 48) to be present in yeast. It was found that, when dried not only at a high temperature (70 C.) but also at 37 C., ordinary pressed yeast yields a yeast-poison when it is subsequently extracted with 0.1 per cent. hydrochloric acid and the filtered extract rendered neutral to alizarin. Different yeasts are affected by this poison in widely differing degrees, Pombé yeast being comparatively slowly killed by it. Another yeast, which was very sensitive to the extract obtained from pressed yeast, was found to yield a poison having an intensely toxic action towards Pombé yeast. The toxic yeast extract is readily attacked by moulds, but acts as a strong antiseptic towards bacteria. Like certain other toxins it is capable of passing through porcelain filters and destroyed by heating to 100 C. It can be completely volatilised by distillation in a current of steam at a temperature not exceeding 40 C., and it can, indeed, be separated from fresh yeast by distilling the latter with a little water in a vacuum, the distillation residue being quite inactive. The distillate, which possesses an activity equal to, or greater than, that of the yeast extract, gives none of the reactions for aldehydes.—T. H. P.

Wine ; French regulations for the analysis of —. Z. öffentl. Chem., 1909, 15, 262—268.

THE French Minister of Agriculture and the Minister of Commerce and Industry have issued the following regulations for the analysis of wines. The wine should be examined by tasting, &c., immediately the bottle has been opened, and a microscopic examination of the sediment must be made either after the wine has stood for 12 hours or been submitted to centrifugal action ; special attention should be given to the presence of yeasts, acid-forming bacteria, &c.

Alcohol.—This is determined by distilling 200 c.c. of the wine after neutralisation ; about 135 c.c. of distillate are collected, and the specific gravity is taken after diluting to a volume of 200 c.c.

Extract (in vacuo).—Five c.c. of the wine are placed in a flat-bottomed glass basin 70 mm. in diameter and 25 mm. high ; the basin is then placed under the receiver of an air-pump, and a basin containing sulphuric acid is placed over the first basin. The air is exhausted as far as possible from the receiver and the evaporation is allowed to proceed for 4 days at a temperature of 15° C., the residue being then weighed.

Reducing sugars.—One hundred c.c. of the wine are treated with powdered sodium bicarbonate and a small quantity of 10 per cent. lead acetate solution, then diluted to a volume of 110 c.c., mixed, and filtered. The filtrate is treated with sodium bicarbonate and animal charcoal, filtered, and the sugars are then determined by titration against Fehling's solution, the sugar being expressed as dextrose. The decolorised wine may also be examined in the polarimeter.

Sucrose and dextrin.—Should the wine show a considerable dextro-rotation in the polarimeter, it must be tested for sucrose and dextrin. For this purpose the cupreducing power is taken after the wine has been heated for 15 minutes with the addition of 2.5 c.c. of 10 per cent. hydrochloric acid to each 100 c.c. of the wine; the inverted line is treated with sodium bicarbonate and lead acetate before the determination is carried out. The difference between the two sugar determinations multiplied by 0.95 gives the amount of sucrose. Should sucrose not be present, the solution is again examined in the polarimeter, the presence of dextrin being denoted by the dextro-rotation remaining practically unchanged.

Total acidity.—Five c.c. of the wine are heated for a moment to 86° C. to remove carbon dioxide, and then treated with *N*/20 sodium hydroxide solution, using either phenolphthalein or litmus paper as indicator. The titration may also be carried out with standardised lime-water, without an indicator, the end point of the titration being ascertained by the appearance of a turbidity and a dark opalescent precipitate. The total acidity is expressed in mms. of sulphuric acid per litre of wine.

Non-volatile acidity.—The residue obtained on evaporating the wine *in vacuo* is dissolved in warm water, and treated as described above.

Volatile acidity.—This is ascertained by subtracting the non-volatile from the total acidity.

Free and combined volatile acidity.—When a wine contains a large amount of mineral matter rich in alkali carbonates, the suspicion is raised that the wine has been treated with an alkali. If such be the case, the true amount of volatile acidity is not obtained as described above, a part of it being fixed by the alkali, and this acidity must be determined after the alkali salt has been decomposed by the addition of tartaric acid. Five c.c. of the wine are treated with 5 c.c. of *N*/10 tartaric acid solution (prepared with 25 per cent. alcohol), the mixture is evaporated *in vacuo* as described under "Extract," 5 c.c. of *N*/10 sodium hydroxide are added to the residue in order to neutralise the tartaric acid introduced, and the solution is then titrated. The acidity thus found subtracted from the total acidity gives the total volatile acidity. In the case of normal wines the figure obtained is but little higher (from 0.1 to 0.3) than when determined without the tartaric acid treatment.

Total tartaric acid.—Twenty c.c. of the wine are mixed with 1 c.c. of 10 per cent. potassium bromide solution, and 40 c.c. of a mixture of equal parts of ether and 90 per cent. alcohol. After the lapse of 3 days, the liquid is decanted through a small filter, the residue is washed with the ether-alcohol mixture, and then dissolved in water and titrated, using phenolphthalein as indicator.

Potash.—The procedure is the same as for the determination of the total tartaric acid, except that 10 per cent. tartaric acid solution (in 20 per cent. alcohol) is used as precipitant in place of potassium bromide. The residue must be thoroughly washed, and finally rinsed with a little 95 per cent. alcohol to remove any traces of free tartaric acid.

Ash.—Twenty-five or 50 c.c. of wine are evaporated in a platinum basin, the residue is gently ignited until thoroughly carbonised, and is then further ignited at a dull red heat until the carbon has all burnt away. Should the carbon not burn readily, the ash may be moistened with a few drops of water and the ignition continued.

Potassium sulphate.—This is determined in the usual way, the sulphuric acid being precipitated as barium sulphate.

Chlorides. (Denigès' method.)—Red wine. Fifty c.c. of the wine are boiled in a porcelain basin for about 10 minutes; 2 c.c. of pure nitric acid are then added and the mixture is stirred. The colour of the liquid turns red, then yellow, and a coloured flocculent sediment is formed. Should these changes not take place within 1 minute, the mixture is again heated and a further quantity of 1 c.c. of nitric acid is added. Twenty c.c. of *N*/10 silver nitrate solution are next added, the mixture is cooled, transferred to a 200 c.c. flask, and diluted to be marked with water. The solution is mixed, filtered, and to 100 c.c. of the filtrate are added 15 c.c. of ammonia, 10 drops of 20 per cent. potassium iodide solution, and

10 c.c. of potassium cyanide solution, the titre of which exactly corresponds with the *N*/10 silver nitrate solution. The solution is then titrated with *N*/10 silver nitrate solution, the end point of the titration being taken when the solution becomes turbid and appears fluorescent. The number of c.c. of silver nitrate solution required multiplied by 0.234 gives grms. of sodium chloride per litre of wine.

White wine. Fifty c.c. of the wine are evaporated to a volume of 25 c.c., the nitric acid is added, and then, immediately, the silver nitrate solution. After cooling, the mixture is diluted to a volume of 200 c.c., and the determination carried out as described under red wine.

Citric acid. (Denigès' method.)—Ten c.c. of the wine are mixed with 1 gm. of lead peroxide, 2 c.c. of mercury sulphate solution (containing 5 grms. of mercuric oxide, 20 c.c. of concentrated sulphuric acid and 100 c.c. of water) are added, and the mixture is filtered. Five c.c. of the filtrate are placed in a test-tube, heated to boiling, and 1 drop of 1 per cent. potassium permanganate solution is added. When the solution has become decolorised, another drop of permanganate is added, and so on, until 10 drops have been added. Normal wines show a feeble turbidity; wines containing 0.1 gm. of citric acid per litre give a strong turbidity, and a precipitate forms if 0.4 gm. per litre be present. The actual quantity present may be ascertained by comparison with solutions containing known amounts of citric acid.

Foreign colouring matters.—The wine when rendered ammoniacal and shaken with amyl alcohol must not yield any colour to the latter, nor must it dye wool darker than a faint dirty red tint.

A further test for colouring matters consists in treating the wine with an excess of 10 per cent. mercuric acetate solution, then adding a slight excess of magnesia, boiling the mixture, and filtering. The filtrate should remain colourless when acidified with sulphuric acid.

Free mineral acids.—If the quantity of sulphuric acid (sulphate) in the ash of the wine is appreciably smaller than the quantity of total sulphuric acid, it is probable that free sulphuric acid is present. Free hydrochloric acid may be detected and determined in the distillate from the wine.

Sulphurous acid.—One hundred c.c. of the wine are acidified with phosphoric acid and distilled in an atmosphere of carbon dioxide in the usual way. The distillate is collected in a receiver containing iodine solution, and the resulting sulphuric acid is determined gravimetrically and calculated into sulphurous acid.

Salicylic acid, boric acid, hydrofluoric acid, and saccharin.—These are determined by the usual methods.—W. P. S.

Alcoholic liquors: Study of the action of hydrogen peroxide upon —. A. C. Chauvin. *Monit. Scient.*, 1909, 23, 567—570.

HAVING accidentally found that addition of a small quantity of hydrogen peroxide improves the flavour of a brandy and removes any musty odour that may be present, the author has systematically studied the influence of this reagent upon rum, and promises to continue his observations with other varieties of potable spirit. Rum was treated in nearly filled bottles with 1—5 per cent. of hydrogen peroxide for 10 and 30 days. The specific gravity and esters were slightly increased, the alcoholic strength, extract, furfural, and higher alcohols were reduced more or less, while the aldehydes were enormously increased, rising from 146 to 1256 per hundred thousand, the maximum figures being yielded after 10 days. The volatile acidity was increased.—R. L. S.

PATENTS.

Amylaceous materials: Process of treating — to facilitate their disintegration, saccharification, or cooking. A. Boidin. *Fr. Pat.* 399,987, April 8, 1908.

IN preparing raw grain or tubers for saccharification, the cell-membranes protect the starch granules from the action of the heat and water, so that a prolonged digestion is necessary for the complete gelatinisation of the starch. According to the present process, advantage is taken of the extremely powerful solvent action, both on proteins

and cellulose, of cultures of the bacteria which are obtained from the surface of the raw grains themselves. The liquefying bacteria are cultivated in suitable media for 3—4 days and the raw amylaceous material, whole or crushed, is steeped in the liquid at a temperature of 50° C. for 3 hours. The operation is ended when the material can be crushed between the fingers. The disintegration of the cell membranes is accompanied by a modification of the starch, which, after this treatment, no longer possesses the property of forming a paste with hot water. Consequently a very short digestion of the material under pressure is sufficient to yield a mobile solution of starch, which is ready for saccharification by the "amylase" process or otherwise.—J. F. B.

Liquefying diastase and diastatic extracts and meals; Preparation of —. H. J. B. Bombart. Fr. Pat. 399,792, Feb. 17, 1909.

A DIASTATIC preparation, which possesses only liquefying properties towards starch paste, is obtained by making an infusion of malted barley at a temperature of 75°—80° C., the final temperature being 80° C. An extract of soluble starch is prepared by the action of this diastase on plain or mixed farinaceous substances or starch in presence of water at 80° C. Diastatic meals are also prepared by mixing the diastase and starchy materials in the dry state, the proportions being 80 parts of starch to the diastase from 20 parts of dry malt.—J. F. B.

Brewing; Process of —. P. Landouzy. Fr. Pat. 399,181, Feb. 6, 1909.

For brewing purposes, the malt is first ground in a mill, and the grist and meal are separated from the bran by sifting and grading, with or without the help of a blast of air. The grist and meal are brewed together, and the mash is clarified in a filter or other suitable apparatus; the bran is not used in the process.—J. F. B.

Wine, beer, cider, perry, and other beverages; Sterilisation and improvement of — by means of mercury vapour lamps. J. Courmont and T. Nogier. Fr. Pat. 400,003, Mar. 1, 1909.

THE liquid to be sterilised is submitted to the action of the rays emitted by mercury-vapour lamps. The lamps may be suspended above the surface of the liquid or immersed in it.—W. P. S.

Wine, brandy, or alcohol; Process for developing a mature flavour in —. J. Roussel. Fr. Pat. 400,256, May 26, 1908.

THE wine, or other alcoholic liquid, is placed in a closed vessel where it is agitated with a quantity of added yeast. From 100 to 1000 grms. of moist yeast are used with every 100 litres of wine, and the mixing is continued for from 8 to 12 hours. The yeast is then removed by filtration; in the case of brandy or alcohol, the liquid may be re-distilled. The bouquet produced is dependent on the kind of yeast employed and on the duration of the mixing operation.—W. P. S.

Mares, pulps, etc.; Apparatus for the continuous distillation of —. A. and M. Garnier. Fr. Pat. 400,282, Mar. 3, 1909.

THE apparatus consists of a number of superposed inclined tubes which are connected alternately to a similar set of tubes inclined in the opposite direction, so that a lengthy continuous passage is afforded for the pulp. This is introduced at the end of the uppermost tube and forced through the apparatus by means of helical conveyors fitted in the tubes. Steam is admitted into the lowest tube and escapes, together with the alcoholic vapours, through a dome placed on the uppermost tube. The conveyors in the lower tubes are caused to move more slowly than those in the upper tubes and the steamed residue leaves the end of the bottom tube through a counterpoised valve.—W. P. S.

Wood; Apparatus for converting — into fermentable sugars and other products. Comp. Indus. des Alcools de l'Ardeche, Paris. Eng. Pat. 26,619, Dec. 8, 1901. Under Int. Conv., June 9, 1908.

Treating wood during distillation. U.S. Pat. 930,274. S. XVIII.

XVIII.—FOODS; SANITATION; WATER PURIFICATION, & DISINFECTANTS.

(A.)—FOODS.

Milk-sugar {lactose} in milk; Determination of —. Michaelis and Rona's "iron method." K. Oppenheim. Chem.-Zeit., 1909, 33, 927—928.

MICHAELIS and Rona's method (Biochem. Zeits., 1907, 329; 1908, 13, 121; 14, 476; 1909, 16, 60) for determining sugar in serum, etc., was applied to milk as follows: 10 c.c. of the milk were diluted with 13 c.c. of distilled water, after which 7 c.c. of colloidal ferric hydroxide solution were added drop by drop with continual shaking. The liquid was filtered through dry filter-paper, and the filtrate polarised in a delicate Schmidt and Haensch polarimeter. The results obtained agreed within about 0.3 per cent. with the obtained gravimetrically, the polarimeter results being uniformly higher. Good agreement with the calculated value was also obtained when known quantities of lactose were added to samples of milk containing known amount of sugar.—A. G. L.

African food grains; Some —. Bull. Imp. Inst., 1909, 7, 145—154.

Maize from S. Nigeria.—Several samples were examined but were mostly damaged by weevils. If preventive measures against weevils were organised, and steps taken to eliminate inferior varieties of the grain, it is probable that exports of maize from S. Nigeria could be largely increased, the local "white maize" being of fine quality. *Guinea corn (Sorghum vulgare) from N. Nigeria.*—One sample each of red and white Guinea corn ("red dari" and "white dari") were examined and were valued at 24s. and 26s. respectively per 480 lb. (Nov., 1907).

Rice from N. Nigeria.—The single sample examined consisted of large, partially cleaned, rather dark-coloured grains; it was valued at 9s. 6d. per cwt., quay terms (Nov., 1907), and considered to be equal to average Bengal rice.

Millet from S. Nigeria.—Samples of brown and grey millet were valued at £4 13s. 4d. and £5 2s. 8d. respectively per ton c.i.f. London (July, 1908).

"Tamba" millet from N. Nigeria.—The sample consisted of very small, round, reddish-brown seeds, with thin hard coats. The seeds contained 75 per cent. (by difference) of starch and only 5.3 per cent. of proteins; they would probably be saleable as a cattle-food at about £4 10s. per ton c.i.f. The grain is used in Nigeria for the manufacture of an intoxicant called "tamba."

Bobu (Ehusini corucana) grain from Uganda.—A sample of the small, round, reddish-brown grains, of which 10 weighed 6.25 grms., was valued at £4 10s. to £5 per ton c.i.f. delivered weights in London (Oct., 1908); it was classed as a small millet.

"Bambarra groundnuts" from N. Nigeria.—The sample consisted of pale buff-coloured seeds, with black spots round the hilum. The seeds, which are derived from the leguminous plant, *Peanutia subterranea*, contain 6.2 per cent. of fat and 16 per cent. of proteins, and whilst used as a cattle-food, could not compete with beans, peas, lentils, cottonseed cake, etc.

Seeds of Hibiscus subdariffa from N. Nigeria.—The seeds are of a dark greyish-brown colour, and have a faint musk-like odour. They contain 19.8 per cent. of fat and 26.8 per cent. of proteins, but would not be of much

service as a cattle-food, owing to the large content of indigestible "crude fibre" (15.5 per cent.), and the hard nature of the seed-coat.—A. S.

sulphurous acid in commercial gelatin. Lange. See XIV.

Determining mineral constituents in plants. Garbarini. See XXIII. Org. Quant.

Pure Food Act (1908): New South Wales. (See this J., 1909, 902.) [T.R.]

THE following are some of the standards and regulations laid down in the Act:—

Guarantee.—The forms of guarantee are prescribed which have to be given by individuals and companies, and packed goods may not be sold without a reference to the guarantee.

Colouring and flavouring.—The presence of colouring-matters and flavourings foreign to the food or drug must be indicated in one of three forms: "artificially coloured," "artificially flavoured," "artificially coloured and flavoured." The size of the printing type is indicated. The regulation does not apply to butter and cheese mixed with harmless vegetable colouring-matter.

Preservatives.—The regulation dealing with the use of preservatives forbids the use of preservatives other than salt, sugar, spices, wood-smoke, vinegar, and acetic acid, except where specifically allowed, and then the quantity and name of the preservative has to be indicated on the package in letters of a certain size.

Dietetic essences.—Essence of lemon must contain not less than 5 per cent. of lemon oil, for which the standard is an optical rotation at 25° C. of not less than +60° in 99-mm. tube," and "4 parts per cent. by weight of citral." Terpeneless essence of lemon must contain "not less than 0.2 part per cent. by weight of citral derived from oil of lemon." There are directions reserving the use of the words "vanilla" and "vanillin" to the natural products unless associated with the word "substitute." The vanilla essence must contain "not less than two-twentieths of one part per centum of vanillin."

Cocoa, if a mixture with starch, must be labelled with the proportion of starch present. The added alkali in soluble cocoa must not be more than 3 per cent., estimated as potassium carbonate.

Vinegar is defined as "the liquid derived from alcoholic and acetous fermentations." A 4-per-cent. standard is adopted, and mineral acids, lead, arsenic, and copper must be absent. Other varieties of vinegar must be so labelled. Vinegar substitutes must be so labelled.

Cream of tartar.—The standard is 95 per cent., and not more than 2 per cent. of sulphates, calculated as calcium sulphate. The baking-powder standard is the same as that in force in Victoria.

Edible oils and fats.—The sp. gr. of olive oil is 0.916 to 0.918 at 60° F., refractive index from 1.4660 to 1.4680, saponification-value between 185 and 195, iodine-number of less than 70 or more than 90. There must be no red colour with the Halphen test, and the clajdin test must yield a yellowish-white mass and a colourless liquid. Cocoa oil must conform to the olive-oil standard.

Castor oil is to have a sp. gr. of from 0.960 to 0.970, a refractive index of 1.4799, a saponification-value of from 83 to 188, and it must dissolve completely in absolute alcohol and in glacial acetic acid. The size of the lettering on the label is prescribed, and the words "castor oil" have to be followed by the words "for human consumption."

Arsenic-limit.—No food may contain more than a hundred-and-fiftieth part of a grain of arsenious oxide in the pint or pound.

Malt extract must contain not less than 70 per cent. of solids derived from malt, and is to conform to the characters and tests of the "British Pharmaceutical Codex"; but bakers' malt extract is only standardised in regard to the solids. Liquid malt extract is to contain not less than 50 per cent. of solids from malt, and malt and it is to contain 15 per cent. of cod-liver oil. Artificial syrups and cordials may contain not more than 1½ grain of sulphur dioxide to the pint.

Oils: Art of "improving" the odour of vegetable —; and modified cottonseed oil. J. H. Filbert, Baltimore, Md. U.S. Pats. 929,845 and 930,280, Aug. 3, 1909.

(1.) THE vegetable oil is heated with animal crackling at a temperature lower than that at which the oil would burn, and subsequently separated from the animal tissue. The odour of hog's lard, etc., may thus be imparted to the oil. (2.) The oil is impregnated with the "essence of heated animal tissue" in such a way that on heating the product the odour of heated animal matter will predominate.—C. A. M.

Lard substitutes: Art of improving the odour of —; and animal fat product and process of making the same. J. H. Filbert, Baltimore, Md. U.S. Pats. 929,925 and 929,926, Aug. 3, 1909.

(1.) A LARD substitute, consisting of beef fat and cottonseed oil, is flavoured by combining it with "the essence of heated animal tissue." (2.) Animal fat is melted and mixed with hog crackling, the latter being removed when the fat has absorbed the characteristic odour of the crackling.—W. P. S.

Fluids: [Electrical] process for sterilising —. C. B. Bartley, Pittsburg, Pa. U.S. Pat. 930,023, Aug. 3, 1909.

THE liquid to be sterilised is subjected to the action of a direct current of electricity passing between terminals immersed in the liquid; at the same time it is subjected to a disruptive discharge between an immersed terminal and a terminal placed outside the liquid.—W. P. S.

Gelose or extract of marine alga: Manufacture of — as a basis for foods and pharmaceutical preparations. C. de La Guéronnière. Fr. Pat. 399,432, Feb. 12, 1909.

MARINE algae, e.g., a mixture of 75 per cent. of agar-agar and 25 per cent. of *Fucus crispus*, are dried and deprived of their woody portions. They are then washed with sterilised water containing 10 per cent. of salt and 1 gm. of hydrochloric acid per 10 litres. The algae are dried in the oven and ground to a powder. The powder obtained is mixed with 0.5–3 per cent. of roasted wheat flour or potato starch, and is then ready for the particular purpose for which it is required, e.g., soups, confectionery, pharmaceutical preparations, etc. It is used in proportions of 2–5 grms. per litre of water or milk.—J. F. B.

Vinegar from skimmed milk: Process for obtaining —. Cie. Franç. des Produits Lactés. Fr. Pat. 399,991, Feb. 26, 1909.

WHEY is submitted to the action of a ferment in the presence of an organic acid, such as citric acid, in order to invert the lactose. The solution is then fermented and the dilute alcoholic solution is separated into two portions. To one portion is added a quantity of alcohol and a culture of *Mycoderma aceti* which has been grown in a lactose medium. When acetic fermentation has taken place, quantities of this mother liquor are added to the other portion of the dilute alcoholic solution, and acetic fermentation is allowed to proceed.—W. P. S.

(B.)—SANITATION: WATER PURIFICATION.

Sewage-sludge: Recovery of grease from —. Beechhold and Voss. *Gesundh.-Ing.*, 1908, 31, 742—744. *Proc. Inst. Civil Eng.*, 1908—1909, 176, [2], 79—80.

For the recovery of grease from sewage sludge, the authors state that it is not necessary to dry the sludge, and that it may be treated while still in the wet state with an acid, preferably sulphuric acid. By this means the colloids are broken up and rendered more suitable for the subsequent operation of removing the fat. Since the organic matters in sludge are readily attacked by micro-organisms, it is necessary to undertake the process with fresh sludge, which, in accordance with the situation from which it is derived, may contain from 3.38 to 26.79 per cent. of fat. Calculations are given to show the value of the grease which might be furnished by the sewage of the 60 million inhabitants of Germany; this the authors estimate to be worth £3,759,000 per annum. A description is given of certain experiments conducted on a commercial scale with 66 gallons of sludge in each case, to which enough 60 per cent. sulphuric acid was added to render the whole mass acid. This was then heated with a steam coil in a lead-lined tank to a temperature of 60° to 70° C. and mixed with the requisite volume of benzine to dissolve the fatty matters. The mixture was run off into the extractor and stirred continuously, and when thoroughly incorporated, the stirring was stopped, the temperature lowered, and the substance was allowed to settle, when the dissolved grease was drawn off. As the mean of five tests, the above volume of sludge yielded 26.8 lb. of raw fat. It is stated that as the outcome of their practical experiments the authors are convinced that a rational process of fat-extraction from sewage would prove commercially valuable, while the residual sludge would be better adapted for use as a manure.

Purifying effluents from sulphite wood pulp mills.

PATENTS.

Sewage sludge: Treatment of —. J. Grossmann, Manchester. *Eng. Pat.* 16,397, Aug. 4, 1908.

For the purpose of removing fatty acids and grease from the sludge, and producing a manurial residue, the following treatment is adopted. The sludge is dried to a suitable consistence and is then mixed with sulphuric acid. This mixture is then subjected to distillation by superheated steam, and the fatty acids and grease are separated from the distillate. The distillation is carried out in a horizontal vessel, heated externally, provided with a central hollow spindle carrying agitating arms. The superheated steam passes into the hollow spindle and out through perforations in the arms into the material which is being treated. (See also *Eng. Pat.* 19,922 of 1906; this J., 1907, 1077.)—G. W. McD.

Water, sewage, or other foul liquids: Process for the purification of — and means therefor. J. W. Liversedge, Leigh-on-Sea, Essex. *Eng. Pat.* 17,244, Aug. 17, 1908.

The water or sewage is conducted through a pipe to a central tank which may be divided into compartments; the flow of the water is regulated by a valve placed on the pipe. After sedimentation has taken place, the liquid passes through perforations in the walls of the tank and percolates through filtering and aerating material built so as to form a zone or bed round the central tank. The bed has sloping sides and a channel is provided at its foot. The liquid flows into the channel and comes into contact with a similar filter-bed placed outside the first. This arrangement of filter-beds and channels is repeated, to any desired extent, depending only on the dimensions of the walled tank which contains the whole. Each channel is provided with valves and is connected with a main outlet; these valves may be utilised to produce a reverse flow of the liquid for cleansing purposes or for conducting sediment to the central chamber, which is provided with a sludge outlet. Chemicals may be added to the water or sewage while it is in the central chamber.

—W. P. S.

Water: Method and apparatus for the purification of — by centrifugal force. H. Guillery. *Fr. Pat.* 399,713, Jan. 26, 1909.

Water containing matter in suspension is given a centrifugal motion, in an apparatus somewhat similar to a turbine, with the result that the suspended matter is removed.—G. W. McD.

(C.)—DISINFECTANTS.

PATENTS.

Disinfectants: Process for making —. H. Schneider. First Addition, dated Feb. 3, 1909, to *Fr. Pat.* 377,141, April 25, 1907 (this J., 1907, 1026).

DISINFECTANTS similar to those described in the original patent may be prepared by mixing 375 grms. of anhydrous oxalic acid with 750 grms. of phenol at a temperature of about 40° C. The mixture is thoroughly agitated until a sudden rise in the temperature takes place, and the resulting dry product is then pressed into the form of tablets for use. Alkali carbonates may be added to the solid product, or to its aqueous solution, in sufficient quantity to neutralise the oxalic acid portion of the phenolic ester.—W. P. S.

Wool flocks and similar materials: Process for the disinfection and antiseptic impregnation of — for mattresses. W. Waess. *Fr. Pat.* 399,138, Feb. 5, 1909. Under Int. Conv., Feb. 5, 1908.

THE wool is moistened with a 5 per cent. solution of carbolic acid, and allowed to stand for several days. The moistened material is then moved about in a drum, fitted with rotating arms, and heated to 80°—100° C. After drying in a current of air, it is impregnated with a solution of carbolic acid ("carbonic acid" in the claim) which has been emulsified with 2 per cent. of birch tar oil by means of ammonia. On air-drying, a thin film of the tar oil containing phenol is left, and in order to disguise any unpleasant odour, amyl acetate is added.

—G. W. McD.

XIX.—PAPER, PASTEBOARD, &c.

Sulphite wood pulp mills: Purification of effluents from —. P. Klason, Papierfabrikant, 1909, 7, Fest- und Auslandsheft, 26—31, 627—629, 671—672, 701—703, 795—800.

For the disposal of the waste lyes from sulphite pulp mills the correct principle consists in collecting them, with or without the wash-waters, in large reservoirs where they are cooled and aerated. They should then be discharged continuously and regularly into a river of sufficient volume. The main points to be considered are the proportion of water to organic matter and the quantity of oxygen dissolved in the water. If, on account of periods of drought, the volume of the river is restricted, large reservoirs should be provided for the storage of the lyes until the weather changes. According to the author's experience, no ill results whatever will occur from the continuous discharge into a river which ensures a thousand-fold dilution of the lyes, corresponding to the introduction of 100 mgrms. of foreign matters per litre. A flow of 1 cub. metre per second will deal with the by-products from the manufacture of 7½ tons of air-dry cellulose per 24 hours. The average volume of a river may be calculated approximately as 40—60 per cent. of the rainfall over the area drained by it. A reservoir capable of storing the lye and wash-waters for a week should be provided, and designed with a capacity equal to 70 times the weight of daily output of cellulose. The lye, diluted and infected with an equal volume of river water, will undergo a fermentation in the course of 7 days' storage, which will materially diminish the amount of organic matters ultimately discharged into the river. The auto-purification of river-water polluted with sulphite lyes may be divided into three stages. The first is a rapid fermentation of some of the organic matters by organisms

urished by the proteins, phosphates and salts extracted from the wood. The oxygen of the water is rapidly consumed and the carbonic acid increases. When the supply of oxygen fails, the organisms respire at the expense of the organic solids in solution, and powerful reducing processes supervene; this stage is the most noxious, and since the nitrogenous nutrition is limited, it extends over a longer period than the first stage. The final stage consists in a slow restoration of the natural condition of the matter by the action of chlorophyll-bearing algae under the influence of light. Experiments made by the author showed that water, at rest and at a constant temperature, solves atmospheric oxygen only slowly, but that variations of temperature act in the same way as mechanical agitation and cause a rapid aëration. The injuries to wood caused by sulphite lyes are principally indirect, brought about by the general deoxidation of the water; in resin and, in soft waters, the free acid also brings about certain objectionable results; the harm caused by fibres in suspension is practically negligible. Wood contains about 53 per cent. of cellulose, but yields only about 45 per cent. of pulp; the difference may be apportioned as follows: 4 per cent. dissolved by chemical hydrolysis; 1 per cent. sorted out in the cleaning and straining operations, and 1 per cent. discharged with the wash waters. Thus the effluents may be estimated to contain, in suspension, about 2 per cent. of the cellulose output of the mill; only about one-fourth of this suspended matter consists of true fibres, readily removed by sedimentation; the remainder consists of thin-walled parenchyma cells which do not settle out on standing.—J. F. B.

Sulphite-cellulose waste lyes and furfural-sulphurous acid. W. Kerp and P. Wöhler. *Arbb. Kais. Gesundh.-Amt.* 1909, 32, 120—143. *Chem. Zentr.*, 1909, 2, 710—711.

THE sulphur present in sulphite-cellulose waste lyes in the form of sulphurous acid (free and combined) amounts to about one-fifth to one-third of the total sulphur. The proportion of sulphurous acid in the lyes which can be exactly titrated with iodine increases with the dilution of the lye, and on continued titration with iodine, the reaction proceeds in stages; these features are characteristic of the behaviour of sulphurous acid compounds of aldehydes, i.e. combined sulphurous acid may therefore be considered to be present in the form of sulphurous acid compounds of the aldehydic constituents of the lyes, *viz.*, furfural, millin, xylose, mannose, galactose, and levulose. The lyes also contain a substance which, when the lyes are heated, acts as an oxygen-carrier and exerts an oxidising action on the sulphurous acid. The so-called calcium dithionates must be regarded as a mixture of different substances. The reaction constant of the composition of sodium-furfural sulphite in aqueous solution is 0.72×10^{-3} . In neutral solutions equilibrium is attained almost instantaneously, but less rapidly in acid solutions, although the amount of decomposition is considerably greater in the latter case. Combination of sulphurous acid and furfural takes place only at the aldehyde grouping, not at the double linkage, furfural having in this respect as a saturated aldehyde.—A. S.

Celluloid; Products of the explosion and combustion of —. B. Pfyfl and P. Rasenack. *Arbb. Kais. Gesundh.-Amt.* 1909, 32, 1—34. *Chem. Zentr.*, 1909, 2, 763—764.

IN the past few years there have been numerous fires in celluloid factories, and in nearly all instances, cases of poisoning by the fire-gases have occurred. The authors consider that the chief sources of danger are the products of explosion of celluloid, formed at a relatively low temperature. Two series of experiments were carried out. In the first, celluloid was heated until explosion (*i.e.*, sudden evolution of gas) took place, in a tube filled with carbon dioxide, nitrogen, or air at atmospheric pressure, in a vacuum over mercury; whilst in the second the celluloid was burned with, as far as possible, avoidance of explosion. The products of explosion of celluloid, with exclusion of air, consisted chiefly of carbon dioxide and carbon monoxide, nitrogen, nitric oxide, hydrogen cyanide, acrolein, and camphor; oxides of nitrogen other than

nitric oxide were not formed, nor were hydrocarbons and hydrogen. 100 grms. of celluloid yielded 17—18 litres of gas, stable at the ordinary temperature, and consisting of 4—7 litres of carbon monoxide, 7—9 litres of nitric oxide, 3—4 litres of carbon dioxide, and 0.5 litre of nitrogen. 100 grms. of celluloid yielded 0.7 gram of hydrogen cyanide, excluding a small quantity fixed by the acrolein. By explosion of celluloid in presence of air, nitrogen peroxide was formed in place of nitric oxide, and this reacted with the acrolein to form strongly reducing compounds, probably hydroxylamine derivatives. In presence of a sufficient quantity of air, and with small quantities of celluloid, the products of explosion were identical with those of complete combustion (carbon dioxide, water, and nitrogen); no hydrogen cyanide or carbon monoxide was produced on burning 1—2 grms. of celluloid. On burning celluloid with a restricted supply of air, larger quantities of hydrogen cyanide were produced than in the explosion of celluloid, 100 grms. of celluloid yielding about 1.2 grms. of hydrogen cyanide.—A. S.

PATENTS.

Wood pulp; Process for the preparation of — by means of oxides of nitrogen. J. E. Hedén. *Ger. Pat.* 212,838, July 14, 1908.

By the treatment of wood with oxides of nitrogen, oxalic and picric acids are said to be produced in addition to cellulose. According to the present patent, the wood is disposed in towers or other suitable chambers, and is subjected to the action of oxides of nitrogen and of water or dilute nitric acid, passing through the apparatus in opposite directions. It is stated that in this way, the wood pulp (cellulose) is obtained directly in one operation. The strong nitric acid, saturated with oxalic and picric acids, which is discharged at one end of the apparatus, is distilled to remove the nitric acid, and the oxalic and picric acids are recovered from the residue by crystallisation.—A. S.

Fibre; Method of soaking sheet —. I. W. Marshall, Yorklin, Del. *U.S. Pat.* 930,205, Aug. 3, 1909.

AFTER coating one side and the edges of the sheets of fibre with an adhesive waterproofing composition, the sheets are soaked in water to remove the chemicals contained in them.—G. W. McD.

Celluloid; Manufacture of plastic materials, as substitutes for —. S. Assadas. First Addition, dated May 8, 1908, to *Fr. Pat.* 387,537, May 8, 1907 (this J., 1908, 873).

A LITRE of the solvent used for moistening 1 kilo. of powdered nitrated paper, in order to render it non-inflammable, contains colophony (25—200 grms.), stannous chloride (200—400 grms.), ammonium chloride (5—50 grms.), and carbon tetrachloride (5—50 grms.). An alternative solution contains colophony (25—200 grms.), and either ammonium magnesium phosphate or magnesium phosphate (150—400 c.c.) in the "nascent state."—G. W. McD.

XX. FINE CHEMICALS, ALKALOIDS, ESSENTIAL OILS, & EXTRACTS.

Aconite. F. O. Taylor. J. Ind. and Eng. Chem., 1909, 1, 549-567.

THE author gives a critical review of the literature on aconite and the valuation of its preparations. It may be taken as established that the root contains three alkaloids, viz., aconitine (acetylbenzoylaconine), benzoylaconine, and aconine. Dunstan and Cash have shown that aconine and, to a lesser degree, benzoylaconine act as antidotes to aconitine, and methods for the determination of the total alkaloids can give no accurate indication of the therapeutical value of aconite preparations. The best chemical method of assay is that based upon the determination of the ether-soluble alkaloid, but it is pointed out that besides aconitine, benzoylaconine is soluble in ether, and aconine is not completely insoluble. In the author's opinion no chemical method of assay has yet been devised which will give satisfactory results. For the standardisation of aconite preparations on the basis of the therapeutically available aconitine, the Squibb test is recommended as being simple, rapid, and superior in accuracy to chemical methods. The test is as follows:—Dilute the fluid extract (other preparations in proportion) so that 0.1 minim is contained in 1 fluid drachm of solution. Rinse out the mouth well to free the surfaces from mucus and saliva, and hold the 1 drachm of solution in the anterior part of the mouth for exactly one minute, and then discharge it. A distinct aconite (tingling) sensation should be perceived within 10–15 minutes. The proportions recommended by Squibb correspond to 1 part of fluid extract to 600 of water. In laboratory practice the author recommends dilutions of 1 in 700 for the fluid extract of the drug, 1 in 100 for the fluid extract of the leaves, 1 in 3000 for the extract of the root, and 1 in 500,000 for aconitine.—A. S.

Hydrolysis of glucosides by emulsin; Influence of quinol (hydroquinone), gallic acid and tannin on the —. A. Fichtenholz. J. Pharm. Chim., 1909, 30, 199-204.

QUINOL, gallic acid, and tannin all exert a retarding action on the hydrolysis of glucosides by emulsin. The action however is not uniform; it varies both with these compounds and with different glucosides. Thus, quinol has a very powerful retarding influence on the hydrolysis of arbutin, but its action is insignificant in the case of gentiopierin and of amygdalin. Gallic acid entirely arrests the hydrolysis of arbutin by emulsin, and almost entirely that of aucubin; other glucosides showed partial and variable progress of hydrolysis in presence of gallic acid. Tannin also varies in its action with different glucosides. It does not entirely arrest the hydrolysis of arbutin.—J. O. B.

Glycyrrhizic acid in other plants [besides Glycyrrhiza glabra]; Occurrence of —. A. Tschirch and S. Gauchmann. Z. allgem. österr. Apoth.-Ver., 1909, 47, 385–386, 393–394.

THE authors have found glycyrrhizic acid to be present in two plants besides *Glycyrrhiza glabra*. Small fragments of the root of *Periandra dulcis* Mart., from Brazil, were extracted with water, the extract boiled and filtered. The clear liquid was treated with dilute sulphuric acid, the precipitate collected, washed, and drained on porous earthenware. It was dissolved in warm alcohol, cooled, and more alcohol added, producing a precipitate. After standing, the liquid was filtered, and evaporated to dryness. The residue was taken up with alcohol, an equal volume of ether added, the liquid filtered, and again evaporated to dryness. The residue, which was glycyrrhizic acid, was a yellow powder, with a sweet taste. It dissolved in hot water, the solution forming a jelly on cooling. When purified through the potassium salt, and crystallised from hot dilute alcohol, glycyrrhizic acid, $C_{42}H_{62}O_{16}$, formed colourless crystals, melting at 195° C. when dried. The acid agreed in its properties with that obtained from *Glycyrrhiza glabra* (Arch. Pharm.,

1907, 97). *Cortex Monsia* obtained from *Pradosia lactescens* Radlk., which grows in Rio de Janeiro, was also found to contain this acid. The powdered bark was extracted with 70 per cent. alcohol, the alcohol distilled off and taken up with water. The clear aqueous liquid was treated with lead acetate, and the precipitate collected and washed. The precipitate was suspended in dilute alcohol (1:4), and decomposed by means of hydrogen sulphide. The filtered liquid was evaporated taken up with alcohol, filtered, and ether added. After standing, the clear liquid was evaporated to dryness dissolved in hot dilute alcohol, and treated with hide powder to remove tannic acid. On filtering and evaporating to dryness, the residue was found to consist of glycyrrhizic acid.—F. SIBB.

Vanilla in Hawaii. J. G. Smith. Brit. and Col. Druggist, 1909, 56, 208.

THE vanilla plant begins to flower during its second or third year, and continues flower production until seven or eight years old. Cultivation consists in keeping down the weeds and underbrush in the plantation. The vanilla plant only bears pods when the flowers are hand-pollinated. This is a delicate operation not difficult to learn. The pods mature in from six to eight months, becoming hard, thick, and greenish-yellow. They are gathered before ripe. After gathering, the green pods are spread out and exposed to the air for 24 hours, being roughly assorted into grades according to size. After being graded the pods are sweated between the folds of woollen blankets exposed to the heat of direct sunshine. During the period of fermentation the pods turn dark brown, become soft and leathery, and sweat freely. The pods are manipulated for several days until the proper degree of colour and aroma have developed. After fermentation they are dried in the sun for a few hours, and finally in cloth-covered trays, in the shade, with gentle heat. When fully dried—that is, when the pods no longer lose weight, but are still moist and pliable to the touch—they are packed tightly in tin boxes and are again manipulated in bulk for one or two months. When completely cured the pods are sorted to size and colour, tied in bundles, and these packages packed in tin-lined boxes which are soldered when full. The yield per acre in Hawaii has been estimated at about 13,000 pods, producing about 120 lb. of finished vanilla beans, fully cured and ready for the market. The industry is a very profitable one for persons having sufficient means who will give this industry their personal supervision. The price of the vanilla bean depends as much upon the outward appearance of the finished product as upon its actual quality, as indicated by aroma and flavour. Care is therefore necessary at every stage in the growth and fermentation of the crop. Five acres of vanilla in bearing should yield from 8400 to 8500 worth of beans per acre per annum, after the third year. There are vanilla plantations in the Kona district on the island of Hawaii, and in the Kona district of Oahu near Honolulu. Much land is still available which is quite suitable for the cultivation of this crop.

Petitgrain oil; Adulterated —. [Addition of ethyl tartrate and oleic acid]. E. J. Parry. Chem. and Drugg., 1909, 75, 410–411.

TWO samples of petitgrain oil adulterated by the addition of an ethyl tartrate, probably diethyl tartrate, are reported on. They had the following characters:—(A) Sp. gr. 0.908 at 15° C.; $[\alpha]_D^{20} = +8^\circ$; $n_D^{20} = 1.4622$; apparent esters, 48 per cent. (B) Sp. gr. 0.902 at 15° C.; $[\alpha]_D^{20} = +7^\circ$; $n_D^{20} = 1.4635$; apparent esters, 47 per cent. The odour of both was abnormal. When boiled under a reflux condenser, turbidity, increasing to a deposit, was observed. The amount of volatile acids obtained by distillation after saponification was equivalent to only 25 per cent. of the esters found to be present. The non-volatile acid was identified as tartaric acid.

TWO other samples were found to be sophisticated with free oleic acid. These had respectively the following characters:—Sp. gr. at 15° C., 0.904 and 0.9035; $[\alpha]_D^{20} =$

+2°30' and +2°; $n_D^{20}=1.4588$ and 1.4559; apparent esters, 43 and 46 per cent.; acid value, 10 and 15 per cent. The addition of aqueous potassium hydroxide solution rendered these oils semi-solid. This adulteration does not seriously affect the solubility.—J. O. B.

Bergamot; Essential oil of —. [*Adulteration with esters*]. J. C. Umney. *Chem. and Drugg.*, 1909, 75, 411.

THE prevailing high price of bergamot oil has induced a considerable amount of skilful adulteration. For this purpose, orange oil is employed together with sufficient of some foreign ester, to bring the "ester value" of the mixture up to the normal figure. In 1895, the author found the characters of genuine bergamot oil to be:—Sp. gr., 0.882–0.886 at 15° C.; $[a]_D$ not exceeding +15°; residue, not more than 6 per cent. when evaporated on the water-bath; esters, as linalyl acetate, not less than 38 per cent.; solubility in 80 per cent. alcohol, 1:2. Samples of guaranteed "pure" oil recently met with had the following characters: Sp. gr. at 15° C., 0.887; $[a]_D=+19°$ to +22°; esters, 41 to 45.5 per cent.; non-volatile residue, 4.4 to 4.5 per cent. Notwithstanding the normal ester value, the odour of these oils was poor when compared with authentic oil containing 40 per cent. of natural linalyl acetate. The optical rotation of these samples is abnormally high, and the residues low. The residue of normal bergamot oil rarely falls below 5.1 per cent. They proved to contain added terpineol acetate. After saponification, the characteristic lilac-like odour of terpineol was readily detected. These oils were probably mixtures of orange and bergamot oils with added terpineol acetate.

Terpineol acetate readily lends itself to this purpose. Its odour is weak, but pleasant; sp. gr., about 0.960; optically inactive; b. pt., 220–225° C. Commercial samples contained approximately 90 per cent. of the ester. It is now being supplied by manufacturers abroad, with instructions for mixing. Ethyl citrate, ethyl benzoate, and benzyl benzoate are also being offered for similar purposes. Genuine bergamot oil of the present season is found to differ very slightly in optical activity from the samples examined in 1905, the rotatory power ($[a]_D=+17°$) being somewhat higher; the other characters are normal.—J. O. B.

Citronellol and cinnamic aldehyde; Compounds of sulphurous acid with —. W. Kerp and P. Wöhler. *Arch. Kais. Gesundh.-Amt*, 1909, 32, 99–119. *Chem. Zentr.*, 1909, 2, 708–710.

THE authors' experiments were carried out with the addition-compounds of sodium bisulphite and citronellal and cinnamic aldehyde respectively, the sodium salts of citronellal-hydro-, and dihydro-sulphonic acid, $C_{10}H_{17}(HSO_3Na).COH$ and $C_{10}H_{17}(HSO_3Na).CHOH.SO_3Na$, the sodium salt of cinnamic aldehyde-dihydrosulphonic acid, $C_6H_5.CH(SO_3Na).CH_2.CH(OH).SO_3Na$, and phenyl-alphopropionic acid, $C_6H_5.CH(SO_3H).CH_2.COOH$, the addition-compound of sulphurous acid and cinnamic acid see this J., 1899, 169). In aqueous solutions of salts of the normal bisulphite addition-compounds of citronellal and cinnamic aldehyde, the complex anion decomposes into the aldehyde and bisulphite-ions, and the latter then unite with the unaltered complex anion, with formation of the corresponding aldehyde-dihydrosulphonic acid anion. The first reaction proceeds very rapidly in comparison with the second. The dihydrosulphonic acids of citronellal and cinnamic aldehyde, and citronellalhydro-sulphonic acid are much more stable than the addition-compounds of sulphurous acid and the aldehydes. Sodium phenylsulphopropionate is still more stable, yielding no sulphur dioxide even when warmed with sulphuric acid. The dihydrosulphonic acids of citronellal and cinnamic aldehyde are comparable with acetaldehyde-sulphurous acid, with respect to pharmacological action (see this J., 904, 832); citronellal-hydrosulphonic acid and phenyl-alphopropionic acid behave as inert sulphonic acids.

—A. S.

Chemical constitution and pharmacological or physiological action [of medicines]; Relation between —. R. Lüders. *Z. öffentl. Chem.*, 1909, 15, 282–288, 302–311.

THE author gives a summary of the leading facts already known concerning the relation between the chemical constitution and the physiological behaviour of substances used in medicine. Blake in 1839 (*Comptes rend.*, 1839; *Roy. Soc. Proc.*, 1841; *Ben.*, 14, 394; *Amer. J. Science and Arts*, VII., 1874, March) examined the action of metallic salts and found that the higher the valency of an element, the greater is the number of organs which its compounds can affect. Where one element forms compounds which are divided into two isomorphous groups, a member of one group will differ from a member of the other group in its action. For instance, ferric chloride is a haemostatic, whilst ferrous salts have no such action. Blake also found that within isomorphous groups, the toxicity increased with the atomic weight. Botkin (*Centralbl. f. med. Wiss.*, 1885, [48], discovered that solutions of sodium chloride when injected into the blood produced no effect, but that chlorides of other metals raised the blood-pressure. Bonchardat and Cooper observed that the effect of salts of potassium on the blood-pressure was greater than that of salts of rubidium and cesium. However the anti-epileptic properties of the bromides of the potassium group increase with the atomic weight, cesium bromide having the strongest effect. Calcium and strontium salts are almost innocuous compared with barium salts. Uranium is an eminently poisonous metal. According to Priestley (*Phil. Trans. Roy. Soc.*, 166; *J. Anat. and Phys.*, 11) the meta- and pyro-salts of vanadic and phosphoric acids are toxic, whilst the ortho-salts are not so. The organic compounds of arsenic, antimony, and phosphorus are less poisonous than the salts of these elements, and have, consequently, proved of therapeutic use. Krönig and Paul (this J., 1900, 1033) have shown that the activity of metallic salts, especially the salts of mercury, is dependent on the degree of dissociation. Mercuric cyanide and thiocyanate are less germicidal than mercuric chloride. The germicidal action of acids depends on the concentration of the hydrogen ions. With regard to carbon compounds, Richardson (*Med. Times and Gazz.*, Sept.-Oct., 1871) ascertained that the hydrocarbons of the methane series act as anaesthetics, and in large quantities produce cessation of the pulse and death. Schmiedeberg (*Arch. exp. Pathol. u. Pharmacol.*, 20, 201) stated that highly poisonous atom-groupings lose some of their toxicity when more or less substituted by hydrocarbons of the fatty series, for example trimethylarsine is less toxic than arsine. Conversely the activity of hydrocarbons is diminished or even destroyed by combination with other atoms or atom-groupings. Methylamine has similar properties to those of ammonia, but causes no narcosis. The methylation of alkaloids having different actions, produces substances which all paralyse the motor nerve-endings. The introduction of hydroxyl groupings lowers the activity of the fatty hydrocarbons. Hexyl alcohol is a strong narcotic, whilst mannitol is almost a food. Ammonia produces spasms of the throat, but methylamine, whilst equally irritating to the mucous membranes, is less poisonous. If an acid radicle is introduced, inactive substances are produced, such as acetamide. The presence of a nitro- or nitroso-grouping increases the toxicity of aliphatic or aromatic compounds when attached directly to a carbon atom. The nitrites, e.g., ethyl nitrite, lower the blood-pressure and accelerate the pulse. The toxicity of the cyanogen group is diminished by the introduction of alkyl groupings. Formaldehyde has a characteristic irritating and antiseptic action, but with acetaldehyde, propionaldehyde, etc., the action of the alkyl grouping becomes manifest, and after causing some irritation they bring about anaesthesia. The latter action disappears with the introduction of hydroxyl groupings, sugar, for instance, showing no anaesthetic action. Ketones show narcotic action and lowering of the blood-pressure in a smaller degree, and their activity appears to increase with the molecular weight. The introduction of sulphonic

or carboxyl groupings lessens the physiological action; phenolsulphonic acid is less active than phenol. Sulphur compounds become less toxic when the sulphur itself is attached to alkyl groupings. Chlorine and bromine, when introduced into compounds, increase the hypnotic effect, whilst iodine increases the antiseptic action. But iodine when substituted in the side-chain, forms potassium iodide in the body. Of ortho-, meta-, and para-substituted compounds, the latter are generally the most poisonous. The arrangement of the atoms in a group affects the physiological action. *Penicillium glaucum* attacks *d*-tartaric acid, but not *l*-tartaric acid. For higher organisms, *l*-tartaric acid is the most poisonous, coming next is *d*-tartaric acid, and finally racemic acid. *d*-Cocaine produces a shorter anaesthesia than *l*-cocaine, and *l*-nicotine is twice as poisonous as *d*-nicotine. The ammonium bases of alkaloids generally have a curare-like action. Of the two optical isomerides of suprarenine, the laevo modification alone has any therapeutic action. As to the connection between taste of substances and their constitution, the increase of the hydroxyl groupings in the aliphatic series increases the sweet taste, as in glycerol and the sugars for instance. E. Fischer (Ber., 35, 2660) found that *α*-amino-butyric acid had a sweet taste, whilst the *β*-acid tasted less sweet, and the *γ*-acid was insipid. All the antipyretics are derived from one of three substances: quinoline, aniline, and pyrazolone, each of which lowers the body-temperature. Quinine in addition decreases the rate of metabolism, as shown by a lessened output of nitrogen. The tasteless derivatives of quinine, aristoquine and euquinine, are antipyretic, but larger doses are required in malaria. Aniline cannot be used as an antipyretic, as it poisons the blood. This undesirable property disappears in acetanilide (antifebrin), which is a more rapid antipyretic than quinine, but is not a specific for malaria, and has less effect on the metabolism. Phenacetin is the least dangerous febrifuge. Antipyrine and pyramidone are stronger antipyretics than quinine, and do not decrease the metabolism, yet their action is not exactly the same as that of phenacetin. The hypnotics can be divided into four groups. The first includes chloral, trichloroisopropyl alcohol (isopral), and a condensation product of chloral and amylene hydrate known as dermid. These produce sleep, but may have a bad effect on the heart. The second group of hypnotics comprises sulphonal and its homologues, which have the drawback of being insoluble, and possess a tendency to cumulative action. Aldehydes containing no halogen such as paraldehyde and amylene hydrate, belong to the third group. The most important group of hypnotics consists of derivatives of urea, for example, methylpropylurethane (hedonal), diethylmalonylurea (veronal), and others. The sodium compounds of some of these are soluble, and can therefore be injected subcutaneously. Meyer has stated (Arch. f. exp. Path. u. Pharm., 1899, 42, 190) that the narcotic action of hypnotics depends on their ability to dissolve fats. If one of the hydroxyl groupings of morphine be replaced by a methoxyl grouping, codeine is produced, which is less narcotic and analgesic than morphine, and is more stable in the organism. Diacetylmorphine (heroin) differs from morphine in its effects. Substitutes for cocaine to be of use, must contain benzoyl-, ester-, and amine-groupings. This is shown in such local anaesthetics as the hydrochloride of benzoyltetramethyldiaminoethylisopropylalcohol (alypine), the hydrochloride of *p*-aminobenzoyldiethylaminoethanol (novocaine), and others. Organic arsenic compounds have been much used in medicine in recent years. Sodium *p*-aminophenylarsonate (atoxyl), acts upon trypanosomes, but has other actions upon the body which are deleterious. The acetyl derivative (arsacetin) has been used more often, but is still associated with harmful reactions. All the arsenic compounds which exert a destructive action on trypanosomes, have an amino-grouping in the para-position. Ehrlich (Biol. Zentralbl., 6, 214) has found that certain dyestuffs are taken up by definitive organs, "methylene blue" being absorbed by living nerve fibres.—F. SHON.

Ether: Purification of — G. Garbarini. Bull. Assoc. Chim. Sucr. et Dist., 1909, 26, 1165—1168.

On exposure to air, ether acquires oxidising properties.

The author has made experiments with a view to removing the oxidation product contained in ether that has been exposed to air, and has found that a dry preparation of ferrous hydroxide is a suitable reagent for this purpose. The reagent is prepared as follows:—Equimolecular proportions of crystallised ferrous sulphate and finely powdered calcium oxide are intimately mixed; interaction is insured by the presence of the water of crystallisation of the iron salt. If there is a deficiency of this water, the reaction is retarded or even prevented altogether, and to remedy this, 15—20 c.c. of water per 20 kilos. of the mixture are added. The mass acquires a greenish colour which gradually deepens, and much heat is liberated. The product is shaped into the form of a cone and covered with powdered calcium oxide. Directly the ferrous hydroxide shows a sign of oxidising to the ferric state, the preparation (20 kilos.) is added in small quantities to the ether (10,000 litres). The mixing is effected in a special drum of 10,000 litres capacity. The interior of the drum is provided with 4 stops which carry iron chains, whereby intimate admixture of the materials is insured on rotating the drum; the iron chains are padded to prevent too violent contact with the drum. As a rule, with an occasional rotation of the drum, a contact of 24 hours duration is enough. The ether passes from the drum to a filter and thence to a receiver.—L. E.

Butyric acid from alcohol: Formation of — under the influence of the silent electric discharge. W. Löb. Biochem. Zeits., 1909, 20, 126—135.

DURING the action of the silent discharge on moist methane, moist acetylene (with and without nitrogen), aqueous alcohol, and other substances, the author has observed an odour of butyric acid. In confirmation of this, he has now proved that by the action of the silent discharge on aqueous ethyl alcohol vapour, butyric acid (or rather, its ethyl ester) is formed, this being the only higher fatty acid produced. The author has already shown that the alcohol decomposes primarily into hydrogen and acetaldehyde. The fact that butyric acid is derivable from acetaldehyde through aldol, renders it easily understood that all substances which yield acetaldehyde under the action of the silent discharge, can form more or less butyric acid; acetaldehyde itself is formed from, and decomposes into, methane and carbon monoxide, so that, given the condition requisite for even the transient existence of these two substances, a synthesis of butyric acid is possible. Thus, in the decomposition of moist methane by the silent discharge, $\text{CH}_4 + \text{H}_2\text{O} \rightleftharpoons \text{CO} + 3\text{H}_2$, this condition is realised. With regard to the decomposition of alcohol, it cannot be decided whether the aldehyde first formed yields butyric acid directly, or decomposes into methane and carbon dioxide which then react to form this acid. The fact, however, that in all systems in which, by the action of the silent discharge, the possibility of acetaldehyde-formation exists, butyric acid is also formed, proves the genetic relation of the two reactions. If carbon monoxide and methane constitute the primary materials for the synthesis of butyric acid, the synthesis of this acid, like that of the carbohydrates, may be effected from carbon dioxide and water, the only obstacles being of an experimental kind. This synthesis is shown by the following scheme:

Each of these reactions singly, is practicable. The author also points out that acetylene, derived from methane by removal of hydrogen, may be an intermediate product of the decomposition of alcohol by the silent discharge, the acetylene taking up water to form acetaldehyde. He also discusses the relations connecting the reactions effected electrically, with the fundamental biological reaction, the decomposition of moist carbon dioxide, and points out that when the introduction of nitrogen into simple organic compounds is explained, natural organic chemistry will be derivable from this simplest of biological reactions.—L. E.

Nitrogen; Fixation of — by alcohol under the influence of the silent electric discharge. W. Löb. *Biochem. Zeits.*, 1909, 20, 136—142.

BERTHELOT has previously investigated the fixation of nitrogen by alcohol and other organic substances under the influence of an electric discharge (this J., 1898, 464). The author points out, however, that with regard to alcohol and the other substances examined by himself, the conditions are not those assumed by Berthelot. Thus, as a result of decomposition, a number of substances is formed and this fact has necessitated various preliminary investigations, *e.g.*, the influence of the silent discharge on moist nitrogen and moist nitric oxide (this J., 1908, 945). The author has now examined the influence of the silent discharge on the fixation of nitrogen by alcohol of concentration ranging from 50 to 100 per cent. A special form of apparatus was used, and the discharging tube was cooled by cooling tubes placed in the solutions of salt serving as electrodes. In spite of the fact that the temperature of these solutions did not exceed 20° C., the discharging tube always contained sufficient alcohol vapour. The nitrogen is not fixed as such, but first forms ammonia with the hydrogen which is produced. Hence, the alcohol is decomposed into acetaldehyde and hydrogen. The aldehyde is decomposed into methane and carbon monoxide, with the result that formaldehyde is produced, and, by combination of formaldehyde and ammonia, hexamethylenetetramine is obtained. Formic acid and ammonium formate, and ammonium butyrate (see preceding abstract) are also obtained. The author also considers it probable that an amino-acid can be prepared from the simplest primary substances and has observed indications of its occurrence, but his results do not permit of a definite conclusion on this point. If the reaction

can be carried to the further stage,

by means of ammonia and with the co-operation of oxygen, a direct synthesis of glycocoll from the constituents of atmospheric air would be practicable.—L. E.

Iodine exports from Japan. Brit. & Col. Drug., Sept. 4, 1909. [T.R.]

EXPORTS of iodine from Japan during late years have been as follows:—

	Cwt.	Value.
		£
1902.....	35	1,483
1903.....	263	10,117
1904.....	612	26,880
1905.....	535	26,629
1906.....	196	7,896
1907.....	305	10,182

The fall in exports which took place in 1906 was occasioned by the reduction in price made by the European iodine syndicate, which tried to free the market from Japanese competition. About half Japan's iodine exports come to England.

Solubility of silver iodide in sodium iodide solutions. Krym. See VII.

Ammonium phosphate; its volumetric determination. Wilkie. See VII.

Determining iodides and free iodine. Bugarszky and Horvath. See XXIII., Inorg. Quant.

PATENTS.

Organic substances; Reduction of —. F. Bedford, and C. E. Williams, Sleaford. Eng. Pat. 9112, April 27, 1908.

THE authors have improved the process for reducing organic substances described in Eng. Pat. 2520 of 1907

(this J., 1908, 296) by carrying out the reduction under diminished pressure and immediately distilling off the product of reduction under diminished pressure.—J. C. C.

o-Diorydiphenylethanolmethylamine and process of making same. F. Stolz and F. Flaecher, Höchst on Maine, Germany, Assignor to H. A. Metz and Co., New York. U.S. Pat. 930,703, Aug. 10, 1909.

THE hydrochloride of methylaminoacetocatechol (see Eng. Pat. 26,480 of 1903; this J., 1904, 1043) is dissolved in water, and the solution, slightly acidified, is reduced by means of sodium amalgam or other suitable reducing agent, and the impurities are extracted from the solution by means of ether; the solution is then concentrated, filtered, again extracted with ether, and finally treated with ammonia to precipitate the *o*-dihydroxydiphenylethanolmethylamine. The new product melts at about 208° C., is sparingly soluble in water, alcohol, or ether, stable when dry, optically inactive, and possesses astringent and hæmostatic properties.—T. F. B.

Guaiacol-5-sulphonic acid [$\text{OH} : \text{OCH}_3 : \text{SO}_3\text{H} = 1 : 2 : 5$] and its salts; *Process for preparing* —. F. Hoffmann-La Roche und Co. Ger. Pat. 212,389, April 12, 1908.

ACIDYL derivatives of guaiacol are sulphonated, with or without addition of dehydrating agents; the resulting acetylguaiacol-5-sulphonic acid solution is saponified and neutralised, and the resulting guaiacol-5-sulphonic acid isolated as such or in the form of its salts.—T. F. B.

Bromoacetylsalicylic acids; Process for preparing —. Chem. Fabr. von Heyden A.-G. Ger. Pat. 212,422, May 26, 1907.

BROMOACIDYL derivatives of salicylic acid are prepared by the action of the chlorides, bromides, or anhydrides of brominated fatty acids on salicylic acid or its salts, preferably in presence of a basic substance, such as dimethylaniline. Tribromoacetylsalicylic acid has a much more powerful physiological action than the corresponding quantity of acetylsalicylic acid. The new compounds are generally of value for treating the complaints for which acetylsalicylic acid is applied.—T. F. B.

Alkylthiosalicylic acids and their alkyl esters; Process for preparing — substituted in the benzene nucleus. Farbwerke vorm. Meister, Lucius, und Brüning. Ger. Pat. 212,434, Jan. 29, 1907. Addition to Ger. Pat. 203,882, Aug. 23, 1906 (see this J., 1908, 1223).

DERIVATIVES of *o*-diazobenzoic acid (substituted in the benzene nucleus) are treated with a xanthogenate, and the resulting substituted benzoic acid *o*-xanthogenic esters treated with alkylating agents in presence of alkali, when they are converted into substituted alkylthiosalicylic acids or their esters. (See also this J., 1909, 854.)—T. F. B.

Organic liquids; Apparatus for removing water from —. Farbenfabr. vorm. F. Bayer und Co. Ger. Pat. 212,854, April 5, 1908.

THIS apparatus is for use in processes, such as esterification, where water is formed and may return to the apparatus together with the condensed solvent. It consists of a reflux condenser, *a*, connected with a horizontal tube in the lower side of which is a small well, *b*, into which the mixture of condensed water and solvent falls, whence it passes to the separator, *c*; when this is full, the water may be removed by means of the stop-cock, and the solvent returned to the apparatus.—T. F. B.

Products containing iodine; Process for obtaining —, and products obtained thereby. J. Hertkorn, Berlin. Eng. Pat. 17,220, Aug. 15, 1908.

SEE U.S. Pat. 901,709 of 1908; this J., 1908, 1176.—T. F. B.

Cumpher; Process of making —. C. Glaser, Baltimore, Md. Re-issue No. 13,001, Aug. 3, 1909, of U.S. Pat. 864,162, Aug. 27, 1907.

Gelose or extract of marine algae for foods and pharmaceutical preparations. Fr. Pat. 399,432. See XVIII.A.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Silver iodide-gelatin emulsion and plates; Preparation and development of —. R. Jahr. Internat. Congr. Appl. Photography, Dresden, 1909. Chem.-Zeit., 1909, 33, 845.

THE following process is given for the preparation of a fine-grained silver iodide photographic emulsion:—33 grms. of potassium iodide and 15 grms. of gelatin are dissolved in 200 c.c. of water, a solution of 30 grms. of silver nitrate in 200 c.c. of water is added, and ammonia is passed through the solution until the precipitate dissolves. The red emulsion is heated for an hour at 55° C., allowed to set, and washed. After standing 24 hours, it is treated with chrome alum and spread on plates. Its sensitiveness can be increased by heating to 80° C. The plates seem to be better suited for physical than for chemical development.—T. F. B.

Silver subhalides; Action of hydrogen peroxide on —. A. P. H. Trivelli. Internat. Congr. Appl. Photography Dresden, 1909. Chem.-Zeit., 1909, 33, 844.

Pure silver bromide is inactive towards hydrogen peroxide whilst colloidal silver decomposes it into water and oxygen. The absorption compound of silver and silver bromide is converted by hydrogen peroxide into a mixture of silver oxide and bromide. The red photohalide is decolorised, being oxidised to silver oxide and bromide the blue photohalide is converted into the red, and the green into the blue by means of hydrogen peroxide. The double compounds of sodium thiosulphate and silver thiosulphate, obtained by the action of sodium thiosulphate on the photohalides, were analysed, with the result that the green photohalide was found to contain the most silver, and the red the least. It is thus concluded that the photobromides are the subhalides; there is a definite relation between their molecular weights and absorption spectra.—T. F. B.

Dyestuffs; Sensitiveness of — to light. A. F. von Hübl. Wiener Mitt., 1909, 268. Chem. Zeit., 1909, 33, Rep., 436.

DYE STUFFS which alone are tolerably fast to light, become very sensitive to light when present in films prepared from gelatin to which glycerin has been added. This is especially the case with Methylene Blue, Phenosafranine, and "Scarlet"; addition of glycerin has less effect in the case of Crystal Violet and Rose Bengal, and no influence at all on Patent Blue, Fast Red, and Tartrazine. The sensitiveness to light of films coloured with Methylene Blue, is increased 500—1000 times by addition of glycerin (3 c.c. to 10 grms. of gelatin). By addition of certain other substances, *e.g.*, arsenates, the sensitiveness is still further increased, complete bleaching being produced in a few minutes on exposure to sunlight. The bleached films soon recover their original colour when kept in the dark; almost instantaneously when moistened with water. The sensitising action of glycerin is completely destroyed by addition of copper sulphate (1—2 grms. to 10 grms. of gelatin).—A. S.

PATENTS.

Pigment prints; Production of —. W. Triepel, Berlin. Eng. Pat. 7000, Mar. 23, 1909.

A PIECE of pigmented paper, somewhat larger than the silver print to be reproduced, is soaked in water until it lies flat, the silver print, preferably after it has been hardened by alum solution, being likewise thoroughly soaked. The pigmented paper is then impregnated with a solution containing soluble bichromates and ferriocyanides of certain metals, the ferriocyanides and monochromates of which are slightly soluble or insoluble in water. Such metals are particularly iron, and the rare earth metals, such as cerium, didymium, lanthanum, and the like. Or the haloid salts of these metals may be used in conjunction with the bichromates and ferriocyanides of alkali metals. In addition to the above-mentioned salts, other salts of these metals, or of uranium, vanadium, molybdenum, etc., especially such as have a tanning effect on gelatin, may be added to the impregnating bath, and preferably in conjunction with an organic acid, such as acetic acid, and in the presence of a liquid, such as alcohol or glycerol, which increases the absorbing power of the gelatin. The pigmented paper is thoroughly saturated with one of the above impregnating solutions, and brought into contact with the wet silver print for five minutes, after which it is developed in the usual way.—O. R.

Photographic chromated glue images on metal, porcelain, glass, and other impermeable substances; Process for producing —. A. Hans. Ger. Pat. 212,764, May 20, 1908.

SOLUTIONS of glue containing a bichromate and a suitable colouring matter, prepared in the usual manner, are applied by means of a colour spray or atomiser, to the

surface of the metal, glass, etc., to be treated. This surface must be heated to such a temperature that the drops of solution mingle and dry rapidly, so as to produce an even coating, but too high a temperature must be avoided, as it reduces the solubility of the film. After exposing under a negative in the usual manner, the picture is developed by means of water, also applied by an atomiser.—T. F. B.

Film for cinematography; Sensitive —. Soc. Anon. des Plaques et Papiers Photographiques A. Lumière et ses fils. Fr. Pat. 400,385, June 3, 1908.

SEE Eng. Pat. 16,114 of 1908; this J., 1909, 491.—T. F. B.

Pyrophorous substances [flash-lights, etc.]. Eng. Pat. 27,341. See II.

XXII.—EXPLOSIVES, MATCHES, &c.

Cotton; Nitration of —. O. Guttmann. Z. angew. Chem., 1909, 22, 1717.

THE author has made experiments during a period of two years with samples of cotton, from English and German sources, the history of which was known, from their obtaining from the cotton-spinning works to the finished, and in some cases, stored nitrocellulose. Some of the samples of cotton were unbleached, others had been strongly bleached with bleaching powder; and some were highly contaminated with dust, etc. The results obtained confirm those of Piest (this J., 1909, 746), namely that the stronger the degree of bleaching of the cotton, that is, the higher the content of oxycellulose, the more difficult it is to stabilise the nitrocellulose obtained therefrom, and the more soluble is the nitro-derivative in ether-alcohol; and in addition, the lower is the viscosity of the solution.—A. S.

PATENTS.

Gelatin dynamite; Machine for packing —. T. W. Bacchus, Woodbury, N.J., Assignor to The E. I. du Pont de Nemours Powder Co., Wilmington, Del. U.S. Pat. 929,815, Aug. 3, 1909.

THE explosive is fed by means of a worm, from a hopper, through a die-plate containing several holes, furnished with nozzles. A carrier, containing empty cartridge cases, mounted on a rotating table, receives the cartridges issuing from the die.—G. W. McD.

Dynamite heater. A. H. Vannauker, Hazleton, Pa. U.S. Pat. 929,902, Aug. 3, 1909.

THE heating apparatus consists essentially of a vessel similar to a water oven. The trays stop short, both of the back and sides of the oven, and are turned up at right angles so as to prevent the cartridges actually coming in contact with the inside of the oven.—G. W. McD.

Nitroglycerin; Compound for eliminating noxious fumes when exploding —. F. P. Bettanin, Bessemer, Mich. U.S. Pat. 930,030, Aug. 3, 1909.

THE explosive consists of dynamite, potassium chlorate, and pine oil.—G. W. McD.

Powder and explosives; Use of silicates, silicic acids, or their derivatives in —. F. Chailly. First Addition, dated, Feb. 20, 1909, to Fr. Pat. 381,311, Aug. 20, 1907 (this J., 1908, 140).

LAIM is made for the use, as ingredients of explosives, of all metals (excluding aluminium) in a finely divided condition, and all minerals and also emery in the same condition. It is said that such additions render explosives less sensitive to moisture and increase their power.

—G. W. McD.

Nitro-explosives; Apparatus for detecting the spontaneous decomposition of —. J. C. E. Bouchaud-Praceig. First Addition, dated May 4, 1908, to Fr. Pat. 388,142, May 22, 1907 (this J., 1908, 961).

THE explosive is contained in a hermetically sealed case. A capillary tube passes through the lid almost to the bottom of the case and is connected, outside, with a tube containing a reagent sensitive to oxides of nitrogen. This tube is closed by an indiarubber ball which expands and contracts according to variations of temperature and pressure. There is thus a certain amount of movement of the air in the case through the tube containing the indicator, and hence any deterioration, and consequent evolution of oxides of nitrogen, is said to be readily detected.—G. W. McD.

Igniting compositions [matches]; Manufacture of —. H. Schmitz, Paris. Eng. Pat. 9992, Apr. 27, 1909.

THIS is a process for rendering yellow phosphorus more effective as an igniting material and consists in adding the phosphorus to a hot solution of potassium perchlorate and continuously stirring the mixture as it cooks. The potassium perchlorate crystallises out and an intimate mixture of the crystals and the phosphorus is obtained. The phosphorus thus treated does not volatilise to any great extent when exposed to air, and the addition of Venice turpentine still further decreases the volatilisation. The mixture may be heated to a temperature of 75 C., without ignition taking place.—W. P. S.

Matches; Igniting composition for —. L. Stange, Aachen, Assignor to The Chemical Industrial Synd., Ltd., London. U.S. Pat. 930,570, Aug. 10, 1909.

SEE Eng. Pat. 16,453 of 1906; this J., 1907, 353.—T. F. B.

XXIII.—ANALYTICAL CHEMISTRY.

APPARATUS, &c.

PATENTS.

Calorimeter. C. J. Emerson, Providence, R.I. U.S. Pat. 931,189, Aug. 17, 1909.

THE patent relates to a bomb calorimeter having an electrical ignition device. The bomb is supported on an insulating stand in the calorimeter vessel, and the ignition circuit comprises the calorimeter vessel, a contact-pin passing through a porcelain plug in the base of the bomb, a fuse wire passing through the fuel in the fuel-pan, and the body of the bomb itself.—A. T. L.

Gas; Apparatus for analysing —. H. N. Cheney, and H. L. von R. Nickerson, Boston, Mass. U.S. Pat. 922,086, May 18, 1909.

THE apparatus, which is suitable for the rapid determination of carbon dioxide in combustible gases at frequent intervals, comprises an absorption chamber, 12, charged with potash, connected to an inclined graduated tube, 15, and a sample chamber, 25, open at 26, the two chambers being immersed in water. In carrying out the analysis, the gas enters the sample chamber by way of the cock, 23, pipes, 22¹ and 22, stop-cock, 18, and pipe, 24, whilst a passage, 30, in the stop-cock, 18, permits the escape from the absorption chamber of gases from the previous test. The stop-cock, 18, is now turned through 180° and the sample of gas passes through the passage, 30, in the stop-cock into the absorption chamber and forces the potash into the graduated tube, 15, whilst the gas supply from the cock, 23, passes to waste at 27. The volume of gas analysed depends upon the height to which

the liquid rises in the tube, 15, but the latter is calibrated so as to indicate the percentage of carbon dioxide in the sample tested.—A. T. L.

Industrial gases; Continuous automatic registering apparatus for the analysis of — by absorption. C. Andorff. Ger. Pat. 211,389, Aug. 17, 1907.

A DEFINITE volume of the gaseous mixture to be analysed is sucked into a measuring vessel by an automatic mercury pump, and then forced into an absorption vessel connected with a second mercury pump. The unabsorbed gas is next forced by the second pump into a measuring vessel, whilst simultaneously another portion of the gaseous mixture to be analysed is sucked into the apparatus. —A. S.

INORGANIC—QUANTITATIVE.

Aluminium, chromium, and iron; New quantitative precipitation method for —. E. Schirm. Chem.-Zeit., 1909, 33, 877–878.

WHEN aluminium, chromium, and iron are separated as hydroxides by means of ammonia, the precipitate is very voluminous, cannot be easily washed, shows a great tendency to carry down other substances present in the solution, and frequently passes through the filter in the colloidal condition. By precipitating with a mixture of potassium iodide and iodate (see Stock, this J., 1900, 276), a much denser precipitate is obtained, but the method is not generally applicable. The author has found that by using ammonium nitrite as a precipitant in a boiling solution, the precipitate of hydroxides obtained is of good quality, and the method is as generally applicable as precipitation with ammonia. The solution, containing from 0.1 to 0.2 gm. of the metals, is treated with ammonia so long as no precipitate forms and is then diluted to about 250 c.c. Twenty c.c. of a 6 per cent. solution of ammonium nitrite are next added, and the whole boiled vigorously till the odour of oxides of nitrogen is no longer perceptible. After allowing to stand for $\frac{1}{4}$ – $\frac{1}{2}$ hour on the water-bath, the precipitate is washed with hot water, first by decantation and then on the filter, dried, ignited, and weighed. If the original solution contains more than 1 per cent. of ammonium salts per 250 c.c., then in consequence of hydrolytic

dissociation and the small amount of free acid thus produced, the precipitation is not quite complete. In such cases, after expelling the oxides of nitrogen, the solution is rendered faintly ammoniacal.—A. S.

Zinc, copper, and cobalt; Determination of — by means of ammonia. W. Vaubel. Z. angew. Chem., 1909, 22, 1716–1717.

THE author states that zinc, copper, and cobalt can be precipitated quantitatively with ammonia if the solution be first carefully neutralised with sodium hydroxide or carbonate, and excess of ammonia be avoided. The acid solution containing the salt of the metal is first treated carefully with sodium hydroxide or carbonate until neutral to litmus paper. Then in the case of zinc salts a drop of phenolphthalein solution is added, followed by ammonia until a red colour is produced. The whole is then heated to boiling until precipitation is complete. In the case of cobalt salts, the coloration is somewhat difficult to recognise, but good results can be obtained with care, and a slight excess of ammonia is not injurious. With copper salts, ammonia is added until the deep blue colour of cuprammonium compounds first makes its appearance. On heating, the complex salts are decomposed, and the copper separates in the form of the brown oxide.—A. S.

Sulphur in animal charcoal; Determination of total —. E. Selvatici. Bull. Assoc. Chim. Sucri. et Dist., 1909, 26, 1164.

FOR determining sulphur in animal charcoal, the author recommends the following method, whereby precipitation of barium phosphate with the barium sulphate is avoided:—The sample (0.5–1 gm.) is heated with sodium carbonate and potassium nitrate, at first gently, and then gradually to fusion, and kept in this state for about 15 minutes. After cooling, the material is extracted with boiling water, filtered, and washed until no longer alkaline. The filtrate is treated with hydrochloric acid, heated until all carbon dioxide has been driven off, evaporated to dryness to remove nitric acid, taken up with water, and filtered to remove silica. The filtrate is precipitated with magnesia mixture (55 grms. of crystallised magnesium chloride and 105 grms. of ammonium chloride dissolved in water and made up to 1 litre) and ammonia, the filtrate from this precipitate being acidified with hydrochloric acid and precipitated with barium chloride.—L. E.

Iodides and free iodine; Determination of —. S. Bugarszky and B. Horvath. Z. anorg. Chem., 1909, 63, 184–196.

BROMINE, in aqueous solution, reacts with iodine according to the equation: $I_2 + 5Br_2 + 6H_2O \rightarrow 2HIO_3 + 10HBr$, and the reaction may, under proper conditions, be utilised for the determination of iodine or iodides. A quantity of solution, containing not more than 12 mgrms. of iodine, is taken and, if alkaline, is rendered feebly acid by means of sulphuric acid, so that the acidity is less than $N/100$; 50 c.c. of saturated bromine water are added and then water to 100 c.c. The flask is kept for 1 hour in a boiling water-bath, and the contents are then transferred to a larger flask, and the bromine is boiled off as rapidly as possible (5 minutes vigorous boiling should suffice). After cooling, 1–2 grms. of potassium iodide are added and 5 c.c. of 2N sulphuric or hydrochloric acid, and, after 2–3 minutes, the separated iodine is titrated with thiosulphate, $1/6$ of the iodine found representing that originally present. Chlorides and bromides, even in very large excess, in no way interfere with the accuracy of the method, but if bromine water, made from commercial bromine, be used for the determination, its iodine content must be ascertained by a blank experiment. The method is suitable for the determination of iodine in waters, and previous softening or removal of organic matter is unnecessary. The presence of ammonium salts, nitrates, and nitrites does not affect the results, but if manganese or iron salts be present, the titration with thiosulphate should be performed rapidly.—F. SOBX.

ORGANIC—QUANTITATIVE.

Mineral constituents in plants [Sugar beets, etc.]: Determination of —. H. Pellet. Bull. Assoc. Chim. Sucri. et Dist., 1909, 26, 1145—1148.

VUAFLART has shown that in the incineration of vegetable substances, appreciable losses of phosphorus, sulphur, potassium, and chlorine, occur, and has therefore recommended wet methods of analysis (Bull. Assoc. Chim. Sucri. et Dist., 1908, 26, 448—455). The author, however, uses a method for determining phosphoric acid in the sugar beet and many other plants, in which the sample is first carbonised and then extracted; the evaporated extract is added to the residue from the extraction, and on igniting the whole, the normal ash of the sample is obtained and no phosphoric acid is lost. The accuracy of this method is now confirmed by Vuafart. Of course, if the material contains much organic phosphorus, means must be taken to insure that the whole of the phosphorus is converted into phosphates, but beetroot, wheat, and sugarcane, do not contain sufficient organic phosphorus to affect the results obtained by carbonisation and extraction. The same observation applies to sulphur. Vuafart has admitted that ignition with sulphuric acid is preferable to the wet method for the determination of potassium. The author considers that for the determination of this constituent, the method of carbonisation and extraction is quite as applicable as that of ignition with sulphuric acid, and the former method gives satisfactory results for lime and magnesia. Save in very special cases, he will therefore continue to use this method.—L. E.

XXIV.—SCIENTIFIC & TECHNICAL NOTES.

Carbon dioxide: Absorption of — by charcoal. A. E. M. Geddes. Ann. der Physik, 1909, [4], 29, 797—808. Chem. Zentr., 1909, 2, 592.

COCOANUT charcoal was treated with carbon dioxide of less than 1 atmosphere pressure in a quartz vessel con-

nected with a pressure gauge, at the temperatures, 14°, 31°, and 35° C. respectively, until equilibrium was attained. The quantity of gas absorbed was calculated from the reduction of pressure, the volume of the apparatus being known. Equilibrium was reached from both sides, but the results were not concordant, the whole of the absorbed gas not being evolved again on reducing the pressure. The results obtained at all three temperatures may be represented by the equation: $v = ap^n$, where v is the volume of gas in c.c. absorbed by 1 c.c. of charcoal at the pressure, p , and a and n are constants. The value of n increases (0.498—0.588) and that of a decreases (1.356—0.629) with rising temperature.—A. S.

Radio-active parent substances: Chemistry of the —. D. Strömholm and T. Svedberg. Z. anorg. Chem., 1909, 63, 197—206. (See this J., 1909, 259.)

AN extension of the authors' work to the actinium group of radio-active elements shows that actinium X is isomorphous with barium and lead; it is precipitated with barium salts as oxalate and sulphate, but not with lead salts as sulphide or iodide; it, therefore, undoubtedly belongs to the alkaline-earth group. Actinium itself is isomorphous with lanthanum, and radio-actinium with thorium. The isomorphy of thorium 2 (*loc. cit.*) is uncertain. A quantitative comparison has been made for the three radio-active alkaline-earth metals, thorium X, actinium X, and radium, of the ratios of distribution of their salts between a solid and a liquid solvent (thorium nitrate crystals and the corresponding mother liquor); the same value was obtained for all three elements, and at very different concentrations. Striking analogies are pointed out between the radio-active elements of the thorium, actinium, and radium groups.—F. Sodn.

Fractional distillation: The theory of —. W. K. Lewis. J. Ind. and Eng. Chem., 1909, 1, 522—533.

A MATHEMATICAL article on the fractional distillation of binary mixtures.—A. S.

Trade Report.

Port of London dues. Draft Schedule of maximum rates.

THE following list is extracted from the draft schedule prepared by the Port of London Authority. Unless otherwise stated, the rates are per ton:—Acids: Acetic 3s.; Boric, 2s.; Carbolic, liquid or solid, 8d.; Hydrochloric, 1s.; Nitric, 1s. 6d.; Oxalic, 3s.; Sulphuric, 1s.; Tartaric, 2s.; Alizarin, 1s.; Alkali, 5d.; Alum, alum rock, alumina, 1s.; Alum cake, 6d.; Alumite, 3s.; Ammon. carb., nitrate, and muriate, 1s.; Ammonium sulphate, 6d.; Other ammonium salts, n.o.r., 1s.; Ammoniacal liquor, 1s.; Aniline, salts of, or colours, 3s.; Anthracene, 1s.; Antimony regulus, 1s.; Antimony ore, 8d.; Arsenic, 3s.; Ashes, black, 6d.; Pearl and pot ashes, 1s.; Barium oxide, chloride, nitrate, 6d.; Bark for medicinal purposes, 3s.; Bark for tanners, 1s.; Barytes, 2s.; Bauxite, 6d.; Bleaching powder, 5d.; Boraxite, 1s.; Borax, 3s.; Brimstone or sulphur, 4d.; Calcium carbide, 3s.; Chemicals, n.o.r., 3s.; Chloral hydrate, 3s.; Colloidion, 3s.; Copper sulphate, 2s.; Copperas, green, 1s.; Creosote salts, 6d.; Cutch, 1s.; Disinfecting fluid and powder, 3s.; Divi-divi, 1s.; Dyestuffs, n.o.r., 1s.; Dyes from coal tar, 3s.; Dyewood roots, 1s.; Extracts to be used in medicine or for dyeing purposes, n.o.r., 1s.; Extracts of dyewood and of bark for dyeing purposes and all extracts for tanning (description to be stated), 1s.; Galls, 3s.; Gambia pods, 1s.; Gambier, 1s.; Gelatin, 3s.; Glucose, 1s.; Ghee, 1s. 6d.; Glycerin, 2s.; Gums, n.o.r., 2s.; Indianrubber, 5s.; Iodine, crude, 3s.; prepared, per £1 sterling, 1d.; Indigo, 5s.; Kieselguhr and infusorial earth, 1s.; Lime, acetate, 1s.; Lime, borate, 1s.; Lime, gas or spent, 4d.; Lime, muriate, 1s.; Lime, phosphate, 6d.; Magnesium carbonate, 3s.; Magnesium borate, 1s.;

N.O.R.=not otherwise rated.

Manganese oxide, 6d.; Mercury, 6s. 8d.; Methylated spirits, 2s.; Myrobalans, 1s.; Naphthalene, 1s.; Nitre cake, 4d.; Orchella, 2s.; Paris white, 1s.; Petroleum burning oils and spirit, and petroleum lubricating oils, naphtha, benzoline, &c., 1s.; Phosphorus, 3s.; Potash salts, 1s. 6d. to 2s.; Quinine, sulphate of, 4d. cwt.; Quinine, residuum, 3s.; Rosin, 3d.; Saccharin, 1s. 1b.; Sal ammoniac, 1s.; Saltpetre, 1s.; Sheep dip or wash, 1s.; Sumac, 2s.; Soap of all kinds, 10d.; Soda salts, 6d. to 2s.; Soy, 2s. 6d.; Spirits, brandy, 100 gals., 1s.; Other spirits, 100 gals., 1s.; Spirits, in bottles, 1 doz. qts., 1d.; Starch, 1s.; Stearine, 2s.; Strontia, 1s. 6d.; Tallow, 2s.; Tar, coal, 1s.; Tar, Stockholm, 8d.; Tartar, cream of, 2s.; Tartar, crystals and lees, 1s.; Turmeric, 1s.; Turpentine, 1s.; Vaseline, 2s. 6d.; Verdigris, 3s.; Wax, paraffin, 1s.; Wax, other descriptions, 3s.; Zinc salts, 2s. to 3s.

Oil is classified under three headings, Class I. at 1s. per ton, Class II. at 2s. per ton, and Class III. at 4d. per cwt., and include the following items:—(1) Bone, castor, coconut, copra, corn, cottonseed, creosote, fusel, gas, linseed, naphtha (coal tar), naphtha (wood), palm, palm nut, rapeseed, refuse for soap, rosin, soap, tar (not otherwise rated), turpentine, wood naphtha; (2) aniline, chemical; (3) camphor, coal tar. Oil cans and drums (empty) are chargeable at 1s. 6d. per ton, and oilseed cake at 8d. per ton.

Appended to these tables of maximum port rates is an alphabetical list of articles not separately rated with reference in each case to some entry in the tariff in accordance with which the charge shall be made. The following are examples:—

Chemicals not otherwise rated.—Acetone, albumen, calcium chloride, potassium iodide, and other potash salts. *Medicines not otherwise rated.*—Citric acid, citrate of magnesia, nareotine, nicotine. *Dye-stuffs not otherwise rated.*—Gallic acid. *Drugs not otherwise rated.*—Alcohol, citrate of lime, malt extract, Epsom salts, Venice turpentine.

German chemical imports and exports. For. Off. Ann. Ser., No. 4325.

The following table shows the imports and exports of chemical products into and from Germany during the years 1907-08:—

Foreign trade.	Year.	Import.		Export.	
		tons.	£	tons.	£
Total of chemical and pharmaceutical products.....	1907	1,358,774	15,034,750	2,800,205	28,592,350
	1908	1,413,550	15,101,000	2,801,933	27,300,050
Of which—					
(a) Chemical base stuffs, acids, salts and other combinations of chemical base stuffs not otherwise mentioned ..	1907	880,071	9,382,000	2,019,334	9,825,050
	1908	904,970	9,712,300	2,074,005	9,998,300
(b) Dyes and dyeing materials	1907	66,258	967,200	186,496	11,826,909
	1908	62,626	893,650	171,560	10,696,700
(c) Varnishes, lacquers, cements	1907	2,857	191,850	3,602	209,600
	1908	2,411	160,800	3,853	224,350
(d) Ether, alcohol, volatile oils, perfumes, cosmetics	1907	37,300	2,012,350	9,464	1,136,650
	1908	40,421	1,950,400	8,846	1,021,150
(e) Artificial manures	1907	327,072	1,008,850	539,878	1,325,450
	1908	353,436	1,017,450	503,228	1,257,000
(f) Explosives, ammunition, and combustibles	1907	1,403	88,400	13,741	1,630,550
	1908	1,101	75,750	11,784	2,629,650
(g) Chemical and pharmaceutical products not otherwise mentioned	1907	43,214	1,384,450	27,691	2,861,650
	1908	49,115	1,291,250	28,658	

Books Received.

BULLETIN OF THE IMPERIAL INSTITUTE. Vol. VII., No. 2. Price 1s.

This issue contains the results of investigations as to various African food grains, Nigerian cotton, East African sisal hemp, rubber from Southern India, recent discoveries of graphite in British African Colonies; also notes on the occurrence and utilisation of tungsten ores, on peppermint oil, on the tussur silkworm in India, on cocoa cultivation in German Colonies, &c. (See pp. 978, 981, 993, 998).

TRADE AND COMMERCE OF THE CONSULAR DISTRICT OF FRANKFORT, APRIL, 1908, TO APRIL, 1909. For. Off. Ann. Series, No. 4325. Wyman and Sons, Fetter Lane, E.C. Price 8s.

This book includes a lengthy report on the chemical industry of Germany; it deals with the subject generally, and also under the following special headings:—Alkalis, acids, &c.; Bromine; Kali; Manures; Dyes; Nitrogenous products out of atmospheric nitrogen; Tanning extracts; Pharmaceutical industry.

NEW CUSTOMS TARIFF OF THE UNITED STATES OF AMERICA. [Cd. 4856.] Wyman and Sons, Fetter Lane, E.C. Price 10½d.

This is a copy of the Act of Congress, approved Aug. 5, 1909, entitled "An Act to provide revenue, equalise duties, and encourage the industries of the United States, and for other purposes," to the dutiable list of which have been added, as far as possible, the former rates of duty on the articles specified in the new tariff.

DIE THEORIE DER FAERBUNG DER NATUERLICHEN ERDOELE UND DEREN NOTWENDIGE KONSEQUENZEN. Von M. A. RAKUSIN. Verlag für Fachliteratur Ges.m.b.H. Berlin. 1909. Price M.2.

PAMPHLET containing 29 pages of subject matter, including a bibliography. The text is subdivided as follows:—I. Theoretical and experimental. II. Conclusions: (1). Chemical-geological consequences. (2). Probable nature and constitution of the dark-coloured substance of petroleum. (3). Relations between the polarimetry of petroleum and the microscopy and ultra-microscopy of the same. (4). Relations between the polarimetry of petroleum and the spectroscopy of the same. III. Final considerations.

METAL CORROSION AND PROTECTION. References to Books and Magazine Articles. Reprinted from the Monthly Bulletin, July, 1909. [Carnegie Library of Pittsburgh.] Second Edition. Carnegie Library, Pittsburgh, U.S.A. 1909.

PAMPHLET containing 64 pages of bibliographic references to articles and books on the above subject. The classification is as follows:—I. CORROSION. (i). General and theoretical. (ii). Corrosion by electrolysis. (iii). Corro-

sion by salt-water. (iv). Corrosion by vapours. (v). Boiler corrosion. (vi). Pipe corrosion. (vii). Corrosion of structural work. II. PROTECTION AGAINST CORROSION. (i). General. (ii). Cement and concrete. (iii). Enamels and lacquers. (iv). Galvanising and tinning. (v). Magnetic oxide. (vi). Paint. (vii). Paper.

THE LEAD AND ZINC PIGMENTS. By CLIFFORD DYER HOLLEY, Ph.D. First Edition. John Wiley and Sons, New York, U.S. America. Price \$3.00 net. Chapman and Hall, Limited. London. 1909. Price 12s. 6d.

Svo volume, containing 313 pages of subject matter, with 85 illustrations, and an appendix with 14 tables,

and the alphabetical index. The subject matter is classified according to the following scheme:—I. White lead in ancient times. II. Development of the white lead industry in the United States. III. Brands, production, and prices of white lead. IV. Modern application of the Dutch process in the United States. V. The Carter process. VI. The mild process (Rowley). VII. Matheson process. VIII. The sublimed lead pigments. IX. White lead manufacture in Europe. X. Properties of white lead. XI. Lead poisoning. XII. Manufacture of zinc oxide. XIII. Properties and uses of zinc oxide. XIV. Manufacture of leaded zinc. XV. Zinc-lead white. XVI. The oxides of lead. XVII. The lead chromates. XVIII. Lithopone. XIX. Physical properties of white lead. XX. Practical tests. XXI. Art of grinding white lead, pastes and paints. XXII. Analysis of commercially pure white leads. XXIII. Analysis of the zinc pigments. XXIV. Analysis of white lead and paints in oil. XXV. Estimation of water in white leads and paints. XXVI. Qualitative analysis of combination white leads and pastes. XXVII. Laboratory equipment and manipulation.

Patent List.

Where a complete Specification accompanies an Application, an asterisk is affixed. The dates given are (i) in the case of Applications for Patents, the dates of Application, and (ii) in the case of Complete Specifications Accepted, those of the Official Journals in which acceptances of the Complete Specifications are advertised. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

I.—PLANT, APPARATUS, AND MACHINERY.

APPLICATIONS.

- 19,990. Leask. Cooling apparatus or apparatus for treating gases with liquids. Sept. 1.
20,140. Sheard. Filtering apparatus.* Sept. 2.
20,244. Farago. Leaching crystalloids from vegetable and other organic substances in presence of sulphurous acid.* Sept. 3.
20,245. Brun. Linseed preparations for steam generators. [Fr. Appl., Sept. 4, 1908. Addition to No. 25,987 of 1906.]* Sept. 3.
20,254. Moore. *See under II.*
20,305. Deroy. *See under XIV.*
20,380. Farago. Concentrating solutions without heating them.* Sept. 6.
20,462. Suzuki. Evaporators.* Sept. 7.
20,715. Petitpierre. Apparatus for raising liquids. Sept. 10.
20,822. Matter. Concentrating apparatus.* Sept. 11.

COMPLETE SPECIFICATIONS ACCEPTED.

- 19,525 (1908). Smith. Continuous kiln. Sept. 8.
24,328 (1908). Clark (Fellner und Ziegler). Supporting inclined rotary drums. Sept. 8.
27,466 (1908). Hallett. Separating air or other gas from liquids. Sept. 8.
2049 (1909). Fawcett, Preston, and Co., and Shield. Evaporating apparatus. Sept. 15.
8876 (1909). Senn and Klüger. *See under IX.*
11,988 (1909). Draper. Apparatus for separating substances of different specific gravities. Sept. 8.
13,859 (1909). Aktiebolaget Separator. Centrifugal separators. Sept. 8.

II.—FUEL, GAS, AND LIGHT.

APPLICATIONS.

- 19,859. Evans. Smokeless steam fuel. Aug. 30.
19,924. Lumsden. Gas producers. Aug. 31.
19,959. Koppers. Obtaining by-products in dry distillation or gasification of fuel. [Ger. Appl., Sept. 1, 1908.]* Aug. 31.
20,010. Cobbett, de Fazi, and Clausen. Manufacture of filaments for incandescence electric lamps. Sept. 1.
20,158. Tozer. Distilling or carbonising coal and other carbonaceous material.* Sept. 3.
20,237. Simpson. Manufacture and purification of coke. Sept. 3.
20,254. Moore. Retort for making coke and for treating other materials. Sept. 4.
20,304. Fichet and Heurtey. Gas generators. [Fr. Appl., Sept. 23, 1908.]* Sept. 4.
20,309. Glover and West. Distilling coal in vertical retorts. Sept. 4.
22,419. Higgins and Kemp. Motor fuel. Sept. 7.
20,447. Fabry. Recovering the by-products of coal-gas, &c. Sept. 7.
20,492. Duchanoy, Bousquet, and Davicion. Gas producers.* Sept. 7.
20,504. Simonin. Utilisation of the waste of the purification of illuminating gas.* Sept. 7.
20,592. Tully. Retort furnaces for the destructive distillation of coal. Sept. 8.
20,631. Riedel. Extraction of nitrogen and carbonic acid from combustion gases. [Ger. Appl., Sept. 9, 1908.]* Sept. 9.

COMPLETE SPECIFICATIONS ACCEPTED.

- 14,167 (1908). Parker. Apparatus for the destructive distillation of coal. Sept. 15.
18,829 (1908). Rodhe. *See under XXIII.*
26,719 (1908). Fletcher. Apparatus for compressing gas or air for lighting or heating. Sept. 8.
28,462 (1908). Neilson. *See under X.*

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

APPLICATION.

- 19,959. Koppers. *See under II.*

COMPLETE SPECIFICATIONS ACCEPTED.

- 16,617 and 24,209 (1908). Hood and Salamon. Treatment of mineral and vegetable oils. Sept. 15.

IV.—COLOURING MATTERS AND DYESTUFFS.

APPLICATIONS.

- 20,029. Bloxam (Act.-Ges. f. Anilinfabr.). Manufacture of dyestuffs of the safranine series. Sept. 1.
20,127. Soc. Chem. Industry in Basle. Manufacture of orange sulphurised vat dyestuffs of the anthracene series. [Addition to No. 7583 of 1908.]* Sept. 2.
20,649 and 20,650. Chem. Werks formerly Sandoz. Manufacture of substantive disazo dyestuffs. [Ger. Appls., Jan. 2, and July 16, 1909.]* Sept. 9.

COMPLETE SPECIFICATIONS ACCEPTED.

- 2386 (1909). Johnson (Badische Anilin und Soda Fabrik). Manufacture of halogenated indigo. Sept. 8.

2608 (1909). Bloxam (Act.-Ges. f. Anilinfabr.). Manufacture of a monoazo dyestuff especially adapted for making lakes. Sept. 8.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

APPLICATIONS.

19,926. Wooster. Treatment of fabrics for use as belting, fire or garden hose, &c.* Aug. 31.

20,305. Deroy. *See under XIV.*

20,312. Imray (Soc. Chem. Ind. in Basle). Obtaining fast grey prints and vat dyeings.* Sept. 4.

20,645. Palmer. Imparting lustre to yarns, fabric, &c.* Sept. 9.

20,728. Bernhardt. Preserving silk-finish and similar effects on textile goods. [Ger. Appl., July 17, 1909.]* Sept. 10.

COMPLETE SPECIFICATIONS ACCEPTED.

1594 (1909). Murray. Apparatus for supplying liquid to wool fibre. Sept. 15.

4683 (1909). Ellis (Heberlein et Cie.). Apparatus for mercerising textile fabrics. Sept. 15.

VII.—ACIDS, ALKALIS, AND SALTS.

APPLICATIONS.

19,794. Peek. Recovery of ammonia from crude ammoniacal liquors. Aug. 30.

19,920. Carulla. Manufacture of sodium sulphate, hydrogen, and iron oxide. Aug. 31.

20,062. McKechnie and Beasley. Separation of iron and other metallic oxides from solutions, ores, or residues. Sept. 2.

20,289. Moeller. Manufacture and distribution of ozone. Sept. 4.

20,290. Moeller. Production of ozone.* Sept. 4.

20,291. Moeller. Apparatus for bringing ozonised air or ozonised oxygen into contact with liquids. Sept. 4.

20,401. Chem. Fabr. Griesheim-Elektron. Manufacture of sulphuric acid. [Ger. Appl., Sept. 21, 1908.]* Sept. 6.

20,562. Spurge. Apparatus for making ozone. Sept. 8.

20,568. Rollin and Hedworth Barium Co. Manufacture of barium or other compounds.

20,631. Riedel. *See under II.*

20,673. McKechnie and Beasley. Separating iron or other oxides from complex solutions, ores, &c. Sept. 10.

COMPLETE SPECIFICATIONS ACCEPTED.

18,356 (1908). Keogh and Douglas. Manufacture of fusible compounds of aluminium, and recovering aluminium therefrom. Sept. 8.

20,402 (1908). Thom and Pryor. Manufacture of lime and carbonic acid gas. Sept. 15.

3732 (1909). Sinding-Larsen. Manufacture of silicon nitride and metals from metallic silicides. Sept. 15.

11,123 (1909). Friedrich et Cie. Preparation of sodium sulphite and ammonium chloride. Sept. 8.

VIII.—GLASS, POTTERY, AND ENAMELS.

APPLICATIONS.

20,400. Garros. Apparatus for making ceramic ware, glassware, enamelling metals, &c. [Fr. Appl., Sept. 3, 1908.]* Sept. 6.

COMPLETE SPECIFICATIONS ACCEPTED.

18,482 (1908). Solon and Campbell. Purifying the slip or like material used in making china, earthenware, and like goods. Sept. 15.

20,393 (1908). Royer. Glass melting furnaces or ovens. Sept. 15.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

DR. JAMES T. CONROY IN THE CHAIR.

THE OCCURRENCE OF MOULDINESS IN PAPER PULP.

BY CLAYTON BEADLE AND HENRY P. STEVENS, M.A., PH.D.

Abstract.

The authors called attention to the occurrence of mould both in paper and in wood fibres prepared for paper making, and gave the features observed and the proportions of furfural and water extract obtained.

BY-PRODUCTS OF COTTON SEED AND THEIR UTILISATION.

BY CLAYTON BEADLE AND HENRY P. STEVENS, M.A., PH.D.

Introduction.—This communication deals with products of cotton seed which hitherto have been regarded as waste materials. The subject matter is treated under two heads:—(A) The utilisation of cotton separated from the seed hulls as a paper-making material; and (B) the utilisation of the hulls themselves as a foodstuff for cattle. Under "A." is given a description of the physical and commercial qualities of the cotton as mechanically separated from the cotton seed hulls of different seeds by the Minck and the De Segundo separating machines (British Patent 12,718, 1906; this J., 1906, 16). Under "B." is discussed generally the feeding qualities and composition of the hulls and their various ingredients, with particular reference to a process of our own for hydrolysing the cellulose and thereby increasing its digestive qualities (British Patent 14,588, 1904).

In the United States there are produced per annum a million tons of hulls capable of yielding 100,000 tons of cotton by mechanical separation, and employed usefully in the manufacture of high-grade papers.

Before proceeding under these headings, a brief reference to a section of the cotton seed (Fig. 1, reproduced by permission) will serve to show from what part of the seed the different products referred to later, are derived. Having once made this reference we will, however, refer to these products under the names by which they are commonly known in the crushing mills.

The husk of the seed, or spermoderm (S), when ground, is commonly known as "ground hulls," or "hull meal"; while the kernel, or cotyledon (C), after expression of the oil, is known as "kernel meal" or "decorticated cake." The two when ground together and pressed for oil constitute "undecorticated cake." The latter is the form produced in this country; "decorticated" cake is the form produced in America.

"Cotton-seed hulls" consist of spermoderm (S) and the hairs (h). These hairs are the cotton fibres that have escaped the ginning and delinting; they frequently have trumpet-shaped attachment ends, and being very short, unripe, and immature, are of no use for textile purposes.

When the cotton is removed from the "cotton-seed hulls" by mechanical separation, described later, each fibre is plucked as it were from the epidermis (ep). When a more drastic separation is effected, in addition to the cotton, the epidermal cells (ep) come away as well as the layers of the inner brown coat (a, b, and c). When cotton-seed hulls as a whole are treated chemically, as has been attempted for the manufacture of paper pulp, the bleached

Cotton seed. Cross section. S spermoderm consists of ep epidermis with h hair, br outer brown coat with R raphe, w colourless cells, pal palisade cells, and a, b, and c layers of inner brown coat; N perisperm; E endosperm; C cotyledon with aep outer epidermis and iep inner epidermis, s resin cavity surrounded by z mucilage cells; al aleurone grains; k crystal cells; g procambium bundles. $\times 160$. (Winton).

residue consists of palisade cells (pal) in addition to the cotton fibre. These cells are useless for paper, and their presence, as will be hereafter seen, renders the cotton useless for explosives. When cotton-seed hulls are hydrolysed, the cellulose of the cotton fibre (h) and palisade cells (pal) have both to be acted upon in order to break them down to a digestive meal, but in cases where the cotton is previously removed by mechanical separation, then, of course, only the palisade cells are acted upon.

"Cotton-seed hulls" constitute therefore the residue after the decortication of the seed for the removal of the kernel; this product (see table) in the United States alone is produced to the extent of nearly one million tons per annum, with a possible augmentation to nearly double this quantity if the whole of the seed produced could be crushed and submitted to the decortication process.

The returns of United States crushing mills (1907).

Number of active establishments	786
Quantity of seed produced	4,952,402 tons
Quantity of seed crushed	2,564,873 tons
Per cent. of seed crushed to quantity produced	51.8 per cent.
Hulls produced	926,705 tons
Linters	128,243,639 lbs.

The hulls appear to show a diminishing proportion to the seed crushed. In 1895 the proportion of hulls was about 50 per cent. on seed. In 1901 the ordinary proportion was about 45 per cent. of hulls, and 1905 and 1907 the computed average was 36.2 per cent., the diminution being due no doubt to the more complete separation of the "meats" and increased delinting, and to more complete cleansing of the seed. The amount of cotton fibre wasted in the hulls is also a diminishing quantity. In 1887 about 10 tons of hulls from Upland

seed was shipped to this country for experiment, from this we procured a yield of 25 per cent. of cotton. In 1896 the fibre on ginned Upland cotton-seed averaged about 10 per cent., the amount removed by linters 1.1 per cent., and the hulls produced 50 per cent.; thus the actual amount of cotton left in the hulls was, according to this figure, 17.8 per cent. At the present time, the linters (as above) equal 2.2 per cent. on seed or 6.3 per cent. on hulls, leaving only 12 per cent. to 14 per cent. of cotton in hulls. After allowing for further possible improvements there would remain in any event a final residue

As will be seen, the Brazilian cotton-seed hulls yield a far higher percentage of cotton than the U.S.A., namely 25 per cent. as against a possible 10 or 12 per cent.

Three main products were eventually separated from the cotton-seed hulls, namely husk, cotton and meal, in the following proportions:—Husk, 65 per cent.; meal, 7 per cent.; cotton, 25 per cent.; loss due to dust and moisture, 3 per cent.

The following table gives some idea of the ingredients capable of being separated and their composition by analysis:—

	Moisture.	Ash.	Woody fibre.	Oil (ether extract).	Protein.	Carbo-hydrates.	Food units.
	Per cent.	Per cent.	Per cent.	Per cent.	Per cent.	Per cent.	
Separated husk	12.75	2.31	32.35	0.5	3.16	48.93	58
Separated kernel meal containing inner brown coat	10.0	6.1	27.0	7.2	20.6	29.1	99
Gritty meal consisting of fine particles of husk (supermodern)	10.0	2.0	38.0	2.6	2.7	41.8	60
Meal, of chocolate colour, derived from inner brown coat of husk	10.0	6.6	39.0	8.8	10.8	24.8	74
Separated cotton containing dust	7.29	1.52	55.4	3.28	9.7	27.71	48
Separated fibre deprived of dust	7.3	1.5	77.0	2.6	3.5	8.1	23

of not less than 10 per cent. of pure cotton on the weight of the hulls, which, on one million tons of hulls, would be equal to one hundred thousand tons of cotton per annum.

The computed yields of cotton from U.S.A. cotton-seed hulls we summarised as follows:—1887, 25 per cent.; 1896, 18 per cent.; 1907, 13 per cent.; lowest possible minimum, 10 per cent.

During the last 20 years many attempts have been made to use cotton-seed hulls for the manufacture of paper, but without marked success. To completely remove the encrusting matter from the hulls by boiling and bleaching is far too expensive, as was proved by one of us when in 1887 some tons were shipped over and converted into paper. The best results were achieved by boiling in soda to loosen the husk; the cotton was then floated off when agitated in a hollander with a large quantity of water, and an imperfect separation effected before bleaching. This could only be accomplished when raw materials were far more expensive than at present, and before cotton-seed hulls had any market value. Considerable quantities were so treated in this country, special hollanders being equipped for the purpose. Beyond this many processes have been proposed and patented and much money has been wasted, but without yielding any practical results.

Papermaking section.—Dry mechanical separation of cotton from the hulls, as now accomplished by the Minck and de Segundo machines, has put a different complexion on the problem. One form of the Minck mill consists of a fixed vertical cylinder with a fluted lining provided in the centre with a vertical shaft from which project a number of arms or beaters. The agitation produced by these arms, as the material is fed into the top, by some means or other brings about a complete separation of the cotton from the husk, but without reducing the size of the husk particles. The husk being heavy and deprived of its woolly coating, passes to the bottom and discharges through a grating, the cotton is winnowed upwards into a cyclone or other form of "condenser," from whence it is discharged to a baling machine. The other ingredients of the seed if present can be collected at convenient stages by settlement from the air draught. A constant supply of cotton-seed hulls is kept up by mechanical means to each mill, and the separated ingredients automatically removed. The various factors of rate of rotation, diameter of the mill, number and forms of beaters, and rate of speed, which could only be arrived at after much careful study, not only affect the output of the mill, power consumption and the thoroughness of the separation, but they also determine the physical character of the fibre produced; a point of considerable importance to paper-makers.

In November, 1906, from a store containing 2000 tons of cotton-seed hulls from Brazilian seed, were selected bales to represent the average of the bulk. The first trial gave 24.6 per cent. and the second 26.0 per cent. of cotton fibre on the weight of the hulls, the rest being separated husk, with a slight loss for dust and moisture.

The analysis of cotton deprived of dust as now produced agrees fairly closely with published analyses given for raw lint cotton determined in a similar manner.

We have devised a simple method of determining the amount of husk in cotton-seed hulls and other products containing the husk. We convert the cotton fibre into hydrocellulose, dry off in presence of fumes of ammonia and shake in a nest of sieves. The disintegration of the cotton is accomplished without reducing the husk. Not only is a separation effected, but an idea is obtained of the size of the husk particles, points of importance to paper-makers. The following table gives results obtained by this process:—

	Size of husk.	Husk.	Raw Cotton.
		Per cent.	Per cent.
Cotton-seed hulls	Coarse, unbroken.	75	25
Fibrous residue after grinding and sifting to remove loose hulls, ..	Ditto.	58	42
Cotton as originally separated from hulls by mechanical process	Coarse and fine.	11	89
Cotton as separated in 1907....	Very fine.	0.7	99.3
Cotton as separated in 1908....	Ditto.	0.4	99.6

After proving on a small scale the paper-making qualities of the separated fibre and determining how best to treat it, some tons were converted into paper in the best rag mills. After several trials it was found that the cotton could go direct from the bales into the rag boilers and behaved much like rags, but without requiring the preliminary processes of cutting, dusting, etc.; furthermore, the process known as "breaking-in" was dispensed with as the fibres were already short enough.

Full details as to the mode of treatment and physical qualities of the paper* produced have already been published. The points established are, that it is unnecessary to start from staple cotton (i.e. long fibres), as in rags, in order to produce a good strong paper. Furthermore, the strength of the paper depends more upon the hydration of the cotton than upon the length of the fibre. The trumpet-shaped ends of these fibres apparently assist in giving felting qualities, and as has been confirmed in Germany when beaten, these ends become frayed with formation of fibrillae. The paper produced is equal to a good quality "rag" paper and can be made "all cotton," which can hardly be guaranteed with any form of rags which contains also some linens. There is, as can be appreciated by the paper-maker, less consumption of power in beating, as there is no reduction in length of fibre needed as with rags. The function of the beating operation is rather to bruise, brush-out and hydrate.

With rags, the process of "breaking-in," which is here avoided, may absorb nearly as much power as the beating operation proper.

The actual amount of bleached fibre or cellulose contained in the dust-free Brazilian separated cotton, is 80 per cent. to 82 per cent., *i.e.*, the same as lint cotton, with which it agrees in composition. In large scale working we have obtained as high as 75 per cent. yield of paper, but the average is rather lower than this, and can never reach the actual amount of cellulose present, by reason of the loss of some fine fibres during the washing operation. This yield, however, is satisfactory in comparison with rags.

The following table gives the length of cotton fibres obtained from the cotton-seed hulls of Brazilian seed when prepared for different purposes. The results are the mean of 40 measurements in each case.

	mm.
1. Separated to produce "free" working	3.34
2. Separated to produce "wet" working	2.62
3. Separated to produce "wet" working	2.70
4. The foregoing after conversion to half-stuff	1.93
5. The foregoing after conversion into writing paper	0.83
6. Separated to produce "wet" stuff (another consignment) ..	2.27
7. The above beaten to bruise fibres only, <i>i.e.</i> , for strong stuff ..	2.29
8. The above beaten to somewhat reduce length of fibres, <i>i.e.</i> , for fairly thick writing paper	1.65

We have considered so far only the character of fibre separated from United States and Brazilian seed. The hulls from Indian seed, after mechanical separation, gave a fibre which on boiling and bleaching showed a yield only of 38 per cent. to 40 per cent. of bleached cotton; the consumption of soda on the weight of the raw fibre was found to be 7.3 per cent., and the consumption of bleach 14.0 per cent. These figures represent respectively 18 per cent. to 20 per cent. soda and 35 per cent. to 40 per cent. of bleach on bleached product as against the figures of 9 per cent. soda, and 10 per cent. bleach for cotton separated from Brazilian seed. The separated cotton of Indian seed is thus much inferior, in cost of treatment and yield, to that of Brazilian seed.

The raw product Indian separated cotton was found to contain albuminoids, 3.28 per cent.; oil, 5.60 per cent.; ash, 5.67 per cent. Both the ash and oil were high, but on chemical treatment the product yielded a very clean product, although there was considerable difficulty in bleaching, and a high consumption of bleach as compared with the Brazilian separated wool. The average of 40 measurements for length of the raw material showed 1.10 mm. The bleached fibres averaged 1.66 mm.

The figure for length of raw fibre is only about a third of that for Brazilian seed, and that for the bleached fibre only about one-half. The difference in the length of the raw and bleached fibres in the case of the Indian product is due to the fact that many of the very short fibres are washed away, and this can hardly be prevented unless a very fine wire gauze is used on the washing drum. The notoriously dirty condition of Indian seed, is, however, largely the cause of low yield. The mechanical separation of the cotton from the Indian seed is therefore not likely to be as remunerative as that from the Brazilian seed or the United States Upland seed.

Having regard to the freedom of separated Brazilian cotton from husk and the fineness of the husk particles, it has been proved, as was anticipated, suitable for nitration. The actual amount of husk is 0.4 per cent. in the unboiled product; this comes down to about 0.2 per cent. by chemical treatment, breaking up into individual palisade cells when beaten, which nearly all pass through the wire of the wash drum.

The imperfectly separated product which, on chemical treatment, still contains quantities of bleached husk behaves differently from normal cotton when nitrated, but the fibre produced from the properly separated product gives identical results, though it differs structurally from the ripe and mature fibre as used for textile purposes.

Sir Frederic Nathan (this J., 1909, 28, 179), speaking in regard to short fibre from the cotton-seed, inferred that the husk left after chemical treatment produced some non-resistant cellulose, and the final product in consequence gave gum-cotton low in nitrogen, and with a high percentage soluble in ether alcohol. This statement probably refers to the product containing some

5 per cent. of husk cellulose or over. Products containing various proportions from 1 per cent. to 50 per cent. of husk cellulose, as also palisade cells pure and simple, were nitrated by us, and whilst we found the above remarks to hold true of those samples containing residues of the husk, we could not detect any difference between the product as now mechanically separated and afterwards chemically treated, and the ordinary cotton fibre as used for nitration.

Chemically the palisade cells are unsuitable for nitration as we have repeatedly proved. They differ essentially from cotton in consisting of hemi-cellulose. If used in quantity for explosives they produce autoxidation, rendering the explosive unstable. When nitrated alone they give a low yield and behave quite differently from ordinary cotton.

The separated cotton, after boiling with excess of soda under pressure of 8 atmospheres for 8 hours and bleaching, contains from 0.2 per cent. to 0.09 per cent. matter extractable by ether. A sample of this product, only partially purified chemically, was submitted to Dr. Eric Drabble, of the Liverpool Institute of Tropical Research, who made some tests to determine its absorption qualities as a surgical dressing according to methods employed by him.* In water-holding capacity it was found equal to that of defatted "super" cotton wool, superior to non-defatted "super" cotton wool, commercial best cotton wool, and only slightly inferior to defatted "best" cotton wool. The absorption value when measured as rate of rise of water when packed in a tube after 1 hour, is equal to "best" cotton wool, superior to wood wool wadding, wool wool, gauze, but inferior to "super" cotton wool, defatted gauze, and commercial cellulose.

The volumes occupied by 10 grams are as follows:—

Under pressure of—		
50 grams per sq. cm.	87.45 c.c.	Greater bulk than cotton gauze, less than wood wools, cotton wool, and commercial cellulose.
25 grams per sq. cm.	90.63 c.c.	Greater bulk than cotton gauze, less than others.
12½ grams per sq. cm.	95.4 c.c.	Same bulk as cotton gauze, but less than others.
Contraction on saturation at—		
50 grams per sq. cm.	18.4%	Much less than most dressings, only inferior to bleached ramie and surgeons' tow.
25 grams per sq. cm.	16.5%	
12 grams per sq. cm.	15.7%	Less than all except surgeons' tow, defatted cotton gauze, and wood wool.

Dr. Drabble sums up by observing that the material in question came out very satisfactorily in respect of its absorptive capacity, and of its slight contraction when saturated. A further and more purified sample was submitted and the result of tests showed further marked improvements, placing the product still higher.

Cattle-food section.—We have now to consider the utilisation of cotton-seed hulls as a cattle-food. Of recent years, it has in some measure come into use in the United States, where its value has been proved in practice and confirmed by numerous feeding trials made at Experimental Agricultural Stations, particularly when fed with products such as decorticated meal. Its use, however, has not found favour in this country, principally because trade conditions differ here and partly because there are no hulls produced, the whole of the material forming part and parcel of the undecorticated cake.

Decortication, which produces the hulls, has been tried in this country and failed, partly owing to the difficulty of marketing the hulls. In Germany the separated hulls deprived of cotton are ground and used with advantage as a food-stuff.

Cotton-seed hulls, which contain from 12 per cent. to 25 per cent. of cotton by weight, are so inflated by the cotton that they appear to consist chiefly of cotton with an admixture of some hulls, whereas it is exactly the reverse. In this form it is, of course, useless for mixing as a food-stuff.

We have succeeded in converting this fluffy mass into a fine-grained, palatable, sterilised meal, possessing good

* Drabble and Upsher Smith. Quar. Journ. Ind. Comm. Research, Vol. 1, No. 3. Drabble. Quar. Journ. Ind. Comm. Research, Vol. 2, No. 4.

digestive qualities. In the process of conversion the product shrinks to about one-third of its original bulk. The same conversion can be accomplished on hulls from which the cotton has been removed. The process has been employed mostly on Indian cotton-seed hulls where the cotton is too short and too much intermixed with hulls and oil for service in paper-making. The process in question is performed in accordance with British Patent No. 14,588, 1904 (this J., 1905, 853), in specially constructed, steam-jacketed pans provided with stirrers. The material is introduced in charges up to half a ton at a time, together with a small proportion of mineral acid, such as hydrochloric acid, and raised to a critical temperature at which hydrolysis takes place. The reaction is catalytic, inasmuch as the reagent, in so far as it concerns the reaction, never enters into combination, and if need be can be used over and over again. Moreover at a critical temperature the hydrolysis to the condition of hydrocellulose is almost instantaneous. The material is discharged when ready; and for certain purposes is left in bulk whilst still hot until it mellows down to a friable, crisp, brown product, possessing a distinctly sweet taste and smell. The process of maturing can be arrested by cooling the stuff down, in which condition it keeps almost indefinitely. The process is usually pushed to the extent of partial caramelisation. The hydrolysed product has been sold in this condition to makers of compound cakes, &c., or else sold in admixture with decorticated cotton-seed meal. In all about 3000 tons have been prepared and put on the market.

The following is a typical analysis of hydrolysed cotton-seed hulls as prepared in bulk:—

Moisture	10.0
Ash	2.7

Food units	72.0

Inasmuch as cotton-seed hulls vary enormously in analysis according to sources and thoroughness of separation, so does the hydrolysed product. The composition can be kept constant by blending and the addition of small quantities of undecorticated meal. The analysis, even without taking into consideration the food value, with hydrolysed cellulose always shows up better in food units than the raw material from which the product is derived, due to an increase in the figure for carbohydrates. This we can vouch for by the analyses of 20 products before and after conversion.

A great deal of systematic work has been done in the United States on the feeding value of cotton-seed hulls. In one series* the rations tested range from cotton-seed hulls alone, and 7 lbs. of hulls to 1 lb. of decorticated meal, down to $1\frac{1}{2}$ lb. of hulls to one of meal. In the combination of the two constituents it is as though no protein had been digested from the hulls, whilst they had caused a decreased digestibility of the protein of the meal. But the loss in protein is more than counterbalanced by the increased digestibility of carbohydrates. The gains in nitrogen free extract and crude fibre were sufficient to increase, after bringing up the loss from protein, the digestible dry matter from 0.81 per cent. in the 7 to 1 ration to 8.66 per cent. in the 3 to 1 ration. In the light of these experiments it must be inferred that cotton-seed meal does effect and increase the digestibility of cotton-seed hulls.

As to the value of the manure from cotton-cake-fed beasts, it should be remembered that cotton-seed hulls are poor in fertilising constituents, while cotton-seed meal is very rich in them. The value of the manure therefore rises and falls in the proportion of hulls and meal in the rations. And in the words of the report:—"The obtainable manurial value of the rations is in all cases materially greater than the original cost of the foods, making the rations."

Many still regard cellulose as possessing no nutrient qualities whatever and as being valuable only as a bulking

material. As exemplification of this the food units of food-stuffs are still calculated without any reference to the constituent shown in the analysis as "crude fibre." On the other hand investigators such as Kellner* have proved the value of certain forms of cellulose as a food-stuff. Kellner has shown that chemical straw pulp, *i.e.*, cellulose formed by boiling straw with caustic soda, which removes everything but the fibre, is as valuable a food material to the ox as starch, and a more valuable food-stuff than the original straw from which it was produced. The straw cellulose used by Kellner contained 82.1 per cent. "crude fibre" and only 17.6 per cent. of nitrogen-free extractive matter, yet 63.1 per cent. of the energy of the straw cellulose was taken up by oxen as against 58.97 for starch. The digestibility of the "crude fibre" of many foods has for a long time been known, but Kellner was the first to demonstrate the value on a cellulosic residue. On the other hand, cotton fibre is proved to be practically indigestible.

Wolff justifies the exclusion of the "crude fibre" in food-stuffs in arriving at food value on the score of "compensation." He asserts, that a compensation takes place between the digested portion of the crude fibre and the undigested portion of the nitrogen-free extract, especially in the case of ruminants. That is to say, these two quantities are always nearly equal, so that the amount of the nitrogen-free extract found by analysis is an approximate measure of the digestibility of the total non-nitrogenous matter in the food (crude fibre and extract taken together).

The "crude fibre" as shown by the ordinary method of analysis is almost invariably lowered about 5 per cent. when cotton-seed hulls and most other products are hydrolysed by our process, but results as to feeding qualities and digestibility appear to show that the residue returned as "crude fibre" when calculating food units should be classed for the most part as carbohydrates. In order to arrive at the cause of this, a number of experiments were carried out in which hydrolysed cotton was subjected to the digestive action of the fresh contents of bullocks' intestines, and also to the action of a culture of Omelianski's bacteria, but without result. Further experiments were made with straw pulp, using the fresh intestinal contents of sheep and oxen, also the action of a culture of Omelianski's bacteria on hydrolysed cotton. None of these gave any result. The Omelianski culture which slowly attacks cotton seemed to have little or no effect on wood pulp.

We have to explain how a material such as straw cellulose, soluble in water and but little acted on by weak acids and alkalis at the body temperature, is digested by herbivora to the extent of 95 per cent. or more, and the soluble products absorbed by the system. No organic ferment has yet been isolated from the digestive tract of herbivora capable of dissolving cellulose in the same way as starch, fibrin and other food constituents are dissolved.

The large amounts of marsh gas and hydrogen given off with carbon dioxide by herbivora in the course of 24 hours† would seem to point to a bacterial action similar if not identical with that studied by Omelianski. It would only remain to show that the fatty acids formed are readily digested and form valuable food-stuffs.

With a view of differentiating raw cotton fibre from cotton hydrocellulose and raw husk as against hydrolysed husk (the points really at issue), we fed cotton-seed hulls to mice for a period of two months. In some trials the mice were fed on ordinary hulls and cheese of known albumenoid ratio in comparison with treated hulls and cheese. In others they were fed on ground hulls not

* Untersuchungen ueber den Stoff und Energieumsatz des erwachsenen Rindes.

† Boycott and Damant. A note on the quantity of marsh gas, hydrogen, and carbon dioxide produced in the alimentary canal of goats. *Journal of Physiology*, vol. xxxvi., Nos. 4 and 5, Dec. 31, 1907.

Goats produce 10–30 c.c. of a mixture of marsh gas and hydrogen per kilogram per hour, on an average 5 per cent. of the total carbon dioxide, so that an average goat of 20 kilos, produced 9 litres of the mixed gases in 24 hours. Similarly, cows produce a quantity of methane amounting to 2.8 per cent. of the total carbon dioxide given off in respiration.

hydrolysed and containing no cotton (*i.e.*, spermoderm only) as against the same but hydrolysed.

The mice rejected the untreated hulls and husk, eating only the cheese, so that it became necessary to mix the cheese and these products. From determination of "fibre" in the droppings it was found that the cotton and palisade cells of the untreated products were practically unaffected; the figures for digestibility or absorption being only about 5 per cent. The mice readily nibbled the particles of treated hull even when unbroken, and when cheese was provided, they took the hulls in preference to the cheese.

The average cellulose "digestibility" of the hydrolysed products were found to be between 65 per cent. and 75 per cent. with a low albuminoid ratio, but as the albuminoid ratio was increased by compelling the use of cheese in admixture with the ground treated product, the absorption of cellulose diminished. We did not strictly differentiate between the cotton hydrocellulose and that of the palisade cells, because the two were fed more or less together.

The microscopic examinations of the droppings of the mice fed on untreated hulls, showed that the husk had altered very little either in structure or colour, also the cotton fibres were intact as though no action had taken place. On the other hand, the droppings of the mice fed on the hydrolysed product (after making due allowance for effects of conversion process upon structure) showed the palisade cells reduced out of definite outline, and what remained, instead of being hard and granular, was semigelatinous, losing its physical form on application of slight pressure. The cotton fibre appeared as reduced to small particles, at the same time losing its characteristic structure and appearance as though it had dissolved away. Probably the outer cuticle which constitutes about 15 per cent. of the cell wall of the cotton fibre is all that is seen under the microscope, and is the only portion of cotton hydrocellulose not capable of digestion by mice, and we believe the same may be the case with herbivora. At the same time it is quite conceivable that the so-called cuticle is capable of digestion if sufficiently hydrolysed, but that it would be the last to go.

To test the efficacy of hulls treated by the hydrolysing process when fed to sheep, some careful trials were undertaken by farmers at our request. One year sheep (tegs) require a certain amount of cotton meal or similar material when grass fed to prevent them from scouring. A flock of 50 to 100 sheep were fed for three months in this way on a mixture of equal parts of linseed cake and hulls submitted to our treatment, using $\frac{1}{2}$ lb. of hydrolysed product per sheep per day. It was found that the sheep took the meal better than ordinary cotton-seed kernel meal and developed a great liking for it, so that it was difficult to keep them away from the troughs when filling, which they always licked clean, and that it served the purpose required. The hydrolysed meal was found to be efficacious as a preventive to scouring when sheep are fed on turnips.

With a view of ascertaining the fattening qualities of meal containing hydrolysed hull meal, we conducted food trials on 16 bullocks (shorthorns). These bullocks had been previously fed on 5 lbs. of undecorticated cake per head per diem of a well-known brand, from August 11th to Nov. 7th. They then went into a shed where they were fed on 7 lbs. of the same cake per diem until the commencement of the trials on Dec. 7th. They were then branded on the horns, weighed and divided into two lots of eight, so that the gross weight of beasts and average condition should be as equal as possible in each lot. The average gain per beast per week was noticed for a period of three months. The rations for the two sheds were the same in each case, with the exception that the "crude fibre" contained in the cotton cake (Shed No. 1) was partially hydrolysed. No. 2 being ordinary undecorticated cake. The beasts in No. 1 shed showed a decidedly greater rate of increase in weight. Furthermore, of those fed with undecorticated cake, *i.e.*, not hydrolysed, two of the beasts died, whereas none were affected in health by the hydrolysed meal. This may have been a coincidence, but the fact remains that the evil effects due to the cotton fibre in the undecorticated cake is entirely

absent from the meal in which the fibre is converted into hydrocellulose. Our belief is that the cotton fibre as well as the palisade cells of the shell by conversion into hydrocellulose is as serviceable a foodstuff as sugar and starch, and should rank as "carbohydrates."

We estimate that the crushing mills at present existing in different parts of the world should yield 120 thousand tons of cotton of sufficient length for paper manufacture, and upwards of 1 million tons of hulls free from cotton that might be successfully employed as a digestive meal. If the process of decortication is extended, these will be augmented, especially if decorticating mills are extended in India and other parts of the East, as is now contemplated. Where the hull cotton is too short even for paper, as with some Indian seed, the cotton-seed hulls without separation can be worked up as a meal. The raw separated fibre should in our opinion be worth at least £8 per ton (in fact, has already commanded a higher price), and the meal £2—£3 per ton.

DISCUSSION.

MR. ALFRED SMETHAM considered the cause of the gradual decrease in the amount of hulls that had been produced in the United States was that about five years ago the Americans were pressed to give guarantees as to the percentages of the various food constituents of the meals which they were exporting and which were imported into England, and more particularly as to the oil and albuminoids, and they were reluctant to put the guarantee too high. The result was that, whereas prior to 1900 or 1902 it was no uncommon thing to find the albuminoids in cotton-seed meals and cakes to amount to anywhere from 42 to 51, it was now quite the exception to get anything testing over 42. By grinding the hulls very fine and mixing them with the meal the hulls got covered with the cotton-seed meal, and to the inexperienced eye it was difficult to detect the presence of the hulls, and a great number of samples of decorticated meal were to all intents and purposes re-constructed undecorticated meal. To-day the percentage was either 40 or 41 of albuminoids, and the result was that most cotton-seed meals coming over now give tests varying from 37 to 41. Allowance had to be made for anything below 41, but all that was lost was the value of the carbohydrates and the cost of the freight if they were detected. Large quantities of cotton-seed cake and cotton-seed meal were now being received from different countries. At the present day, for the first time to his knowledge, cotton-seed meals and cotton-seed cakes were commencing to come to this country from China. The Japanese were also beginning to send over cargoes, some in excellent condition, some in a more or less "heated" condition, but he had no doubt that when the shippers and the shipowners get to know more of what is necessary, the trade from these two countries would be very considerable. Another new source of supply, in the main due to the efforts of the British Cotton Growing Association, was the West Coast of Africa. The shipments of the cake, so far, had only been a few thousand tons, but if the attempts now being made to grow the cotton there were successful the cake would be available to the English farmer in very much larger quantities in the near future. Oil cake coming from West Africa was undecorticated, the woody fibre amounting to nearly 30 per cent., of which a very large proportion was in the shape of lint, and some means of decortication on the spot of the hulls, which evidently were of a very woody character, would be most valuable. Again, Bumah cotton cake was now being imported in very large quantities, containing up to 27 per cent. of woody fibre, *i.e.*, the hulls plus the lint. These new supplies should be eminently suitable for the processes which the authors suggested for the utilisation of what had hitherto been the waste fibre. He was afraid that the method of converting the hulls into meal for food compounds would hardly commend itself to the British agriculturist. He would like to have details of the process of separating fibre from the hull, which would permit the estimation of the percentage of lint in any feeding meal. There had been numerous cases where damage had been done to sheep by the consumption of cake containing large

proportions of cotton wool, and therefore the cotton wool should be eliminated, as far as practicable, from all cattle foods.

Mr. H. B. Stocks asked the authors to outline the method mentioned, for hydrolysing the hulls. In what way was the material treated with hydrochloric acid, and how was the acid subsequently neutralised or eliminated?

Mr. J. MORTON asked if any work had been done on separating the cotton and the hulls after they had been made into cake.

Mr. BEADLE thought Mr. Smetham's definition of a reconstructed undecorticated meal a very apt one. He understood that decortication plant had been shipped to Burmah and China, but whether decortication was going on in those countries he did not know. The usual belief in this country was that the ordinary process of decortication as applied in the States was not applicable to the Indian seed, but he was of opinion that certain types of the American "hullery" could be used for this purpose. As far as he could see from the machines he had inspected in operation in France, the plant and process were as available for Indian seed as for American, and the separated products seemed to come up to the usual standard. The hydrolysis of the meal was conducted by incorporating with the hulls a small amount of hydrochloric acid in suitable plant, such as by the employment of a "kettle" with a mechanical stirrer. The temperature was raised by means of a steam jacket to a little below 120° C., at which temperature an aqueous solution of hydrochloric acid volatilised. Just before reaching the temperature at which it was volatilised, the critical temperature at which the hydrocellulose was produced was reached. But in lieu of removal of excess of acid as above, the easiest way of neutralising was to add a small amount of soda ash, in a very fine state of division, so that in the final product contained about 0.5 per cent. of common salt. If the hydrolysed meal were used by mixing it with kernel meal, etc., these latter substances contained sufficient basic constituents to combine with and neutralise any acid of the hydrolysed meal, so that the mixture no longer contained hydrochloric acid. The reaction at the critical temperature was practically instantaneous. The process was worked intermittently, the time taken before discharging being merely that due to heating to the required temperature. Their laboratory method for the estimation of fibre and husks could be applied to such products as hulls and many other mixtures containing husks and cotton. The separation could be made by introducing hydrochloric acid and shaking it in a stoppered bottle whilst heating to about 110° C. If there was a considerable portion of hulls, by mere shaking the cotton would go to the condition of a powder, leaving the hull particles intact. This mass after neutralising with fumes of ammonia and drying off as already explained, could be separated on a nest of sieves, giving one a fairly accurate idea of the size of the hull particles as well as their proportion by weight.

Sydney Section.

Meeting held at Sydney, on Wednesday, July 14, 1909.

ASSISTANT-PROFESSOR J. A. SCHOFIELD IN THE CHAIR.

THE ABSORPTION OF MOISTURE FROM THE ATMOSPHERE BY WOOLS.

BY ALLISTER M. WRIGHT.

Wool is very hygroscopic, and may contain from 8 to 50 per cent. of moisture, according to the conditions of the atmosphere to which it is exposed. This is an important item in the sale of wool, and hence in Great Britain, and on the Continent, the percentage of moisture

contained in it must be officially determined in "wool conditioning" laboratories. The legal amount of moisture allowed in most European countries is 18.25 per cent.

The purpose of this investigation was to determine under what conditions wool absorbs moisture from the atmosphere, and what constituents enable it to absorb relatively large amounts.

It is necessary to distinguish between the true wool fibre, and the incrusting and mechanically adhering matters. The pure fibre consists for the most part of keratine, the characteristic constituent of horn, feathers, &c., and is not of constant chemical composition, but varies in different qualities.

The incrusting and adhering matters consist of: (a) Wool fat or yolk, soluble in hot alcohol; (b) other fatty matter, soluble in ether; (c) suint, which exudes from the body of the animal with the perspiration, and is sometimes known as "wool perspiration," soluble in water; (d) adhering impurities or dirt mechanically mixed with the above, or entangled among the fibres, which is mechanically removed after extracting the fats.

The methods of analysis used are those described by the author (this J., 1909, 28, 104). The water-soluble suint was determined in the portion of the sample remaining after removal of the adhering sand and dirt, as follows:—After drying and weighing, the sample was placed in a Soxhlet extraction thimble and repeatedly extracted with hot water, then dried and weighed, the loss in weight being suint, and the residue pure wool fibre.

The following are the analyses of the greasy and slipe wools of various kinds used in this investigation.

TABLE I.

Greasy wool.

	Half-bred.	Three-quarter bred.	Leicester.	Lincoln.
Moisture	16.90	19.20	17.79	17.18
Wool fat	16.68	12.08	8.94	5.72
Other fatty matter12	.74	.01	.06
Water soluble suint	10.30	12.72	7.81	2.26
Sand, dirt, lime, etc.	3.62	2.94	5.10	5.32
Pure wool fibre	52.08	51.32	50.45	68.56
	100.00	100.00	100.00	100.00

TABLE II.

Slipe wool.

	Half-bred.	Three-quarter bred.	Leicester.	Lincoln.
Moisture	12.78	12.82	13.37	12.67
Wool fat	6.49	5.76	2.53	3.47
Other fatty matter	2.45	2.29	1.82	2.05
Water soluble suint	2.01	1.60	1.20	1.04
Sand, dirt, lime, etc.	2.66	3.72	1.49	3.85
Pure wool fibre	73.61	73.81	75.59	76.92
	100.00	100.00	100.00	100.00

These analyses show that the slipe wools contain a lower percentage of moisture than the greasy wools; the amounts of wool fat and suint are also considerably less in the slipe wools, which is to be expected, as these matters are removed in the washing of the skins. The increase in fatty matters other than wool fat is probably due to the fat and grease on the underside of the skin rubbing against the woolly side during the process of washing.

In determining the amount of moisture absorbed by greasy and slipe wools, the samples were dried, and after weighing were exposed to the atmosphere of the laboratory for from 24 hours to 408 hours, being weighed at regular intervals; at the same time determinations of the relative humidity, and the amount of moisture in grains per cubic foot present in the atmosphere, were made. The results obtained are presented in the following

tables, the amounts of moisture absorbed being calculated on the dry samples:—

TABLE III.
Greasy wool.

Time in hours.	Percentage of moisture absorbed.	Relative humidity.	Grains of water per cubic ft.
24	24.28	80	2.6
32	29.27	85	5.2
48	27.77	85	4.4
72	26.82	72	3.8
144	28.66	82	3.9
168	26.62	76	3.8
192	27.36	85	3.8
216	25.79	70	2.7
240	24.85	65	4.3

TABLE IV.
Slip wool.

Time in hours.	Percentage of moisture absorbed.	Relative humidity.	Grains of water per cubic ft.
24	16.26	80	2.7
26	16.12	75	4.2
48	16.69	81	4.7
72	16.37	78	3.5
96	16.92	80	4.1
144	20.66	95	4.8
168	19.82	87	4.6
180	17.79	69	4.2
192	18.14	80	2.6
200	19.41	85	5.2
216	19.43	85	4.4
240	18.92	72	3.8
312	19.27	82	3.9
336	18.71	76	3.8
369	19.12	85	3.8
384	17.95	70	2.7
408	17.74	65	4.3

The greasy wool thus absorbs from 24.38 per cent. to 29.27 per cent. moisture, whereas the slip wool absorbs under the same conditions from 16.12 per cent. to 20.66 per cent. The amounts also increase and decrease with the relative humidity of the atmosphere, and it is the relative humidity, rather than the absolute amount of moisture present, which determines the amount of moisture absorbed. The amount of water per cubic foot of air bears but little direct relation to the moisture absorbed.

The amount of moisture absorbed by pure wool fibre free from incrustations and adhering impurities was determined, the results being shown in Table V.

TABLE V.
Pure wool fibre.

Time in hours.	Percentage of moisture absorbed.	Relative humidity.	Grains of water per cubic ft.
24	18.02	72	3.8
96	19.50	82	3.9
120	18.90	76	3.8
144	19.62	85	3.8
168	18.47	70	2.7
192	18.19	65	4.3

Pure wool fibre free from all other matters thus absorbs from 18.03 per cent. to 19.62 per cent. under varying degrees of humidity. The above results show that the pure wool fibre cannot be the only matter in normal wool which causes the absorption of moisture, for in the greasy wool containing from 50 per cent. to 60 per cent. of fibre, it is found that the absorption of moisture is from 24 per cent. to 29 per cent., whereas if the fibre were the only factor we should expect to find a moisture absorption of from 9 per cent. to 12 per cent.; and in slip wool containing from 70 per cent. to 80 per cent. fibre, we find a moisture absorption of from 16 per cent.

to 20 per cent., whereas it should be only from 14 per cent. to 15 per cent. There are thus other factors which determine the amount of moisture absorbed. The relatively high amounts of moisture absorbed by pure wool fibre is probably due to the very large surface area presented to the atmosphere in proportion to the weight of the fibre.

A number of wool fibres each 3 inches long were counted and weighed and the following results calculated:—

13,100 fibres of half-bred wool, each 3 inches long, weigh 1 gram.

12,500 fibres of three-quarter-bred wool, each 3 inches long weigh 1 gram.

9,100 fibres of Leicester wool, each 3 inches long, weigh 1 gram.

7,800 fibres of Lincoln wool, each 3 inches long, weigh 1 gram.

If we take the average diameter of each of the above classes of wool as given in the following table it will be found by calculation that the surface area of one gram of wool is as follows:—

	Diameter.	Surface area of 1 gram.
	inch.	sq. inches.
Half-bred	0.0008	98
Three-quarter-bred ..	0.0010	118
Leicester	0.0016	136
Lincoln	0.0018	132

The surface area is thus an important factor in determining the amount of moisture absorbed by the fibre.

The wool fat was examined, and it was found capable of absorbing up to 17.2 per cent. moisture when spread thinly on a watch glass, but even with the inclusion of this factor it is not possible to account for more than one or two per cent. of the moisture absorbed by the normal wool fibre.

The water-soluble suint, or wool perspiration, was examined, with the result that it was found that very large amounts of moisture were absorbed by this constituent. The following table shows the results obtained:

TABLE VI.
Water soluble suint.

Time in hours.	Percentage of moisture absorbed.	Relative humidity.	Grains of water per cubic ft.
24	60.43	76	3.8
48	66.42	85	3.8
72	65.50	70	2.7
96	63.55	65	4.3
120	64.76	72	3.4
144	66.24	80	3.8

The moisture absorbed thus varies with the relative humidity, and the suint, although present in the proportion of only one or two per cent. in some wools, and up to 12 per cent. in others, is responsible for a relatively large amount of moisture absorbed by the normal wool fibres.

In slip wools this material is largely washed out during the treatment of the skins, and its presence in greasy wools accounts for the increased power of moisture absorption shown by these wools. In determining the absorption of moisture by slip wools it was found that the fatty matter other than wool fat, which is present in slip wool to a greater amount than in greasy wools, had the power of slightly retarding the absorption of moisture. In the following experiments, the natural wool fat was first removed by extraction with hot alcohol, the wool after drying and weighing was exposed to the atmosphere, and the amount of moisture absorbed determined; then the other fatty matter was extracted with ether, and after drying and weighing, was again exposed to the atmosphere under similar conditions of relative humidity, and the moisture absorbed noted. In all cases the wool absorbed more moisture when the foreign fatty matter was removed than in its presence. The results obtained are shown in the following table:—

TABLE VII.

Foreign fatty matter.	Percentage of moisture absorbed in presence of fatty matter.	Percentage of moisture absorbed in absence of fatty matter.
Per cent.		
2.06	10.70	11.07
2.16	9.38	9.92
2.60	9.22	9.08
2.88	9.08	10.18
3.28	9.95	11.13

The fatty matter probably forms a film over the surface of the wool, and being itself impervious to moisture thus retards to a certain extent the moisture absorption by the fibre and the other constituents of the wool. Another point of considerable interest in connection with the foreign fatty matter present in slipe wool is that it is an oxidisable fat, and it is probably this fat which caused the rise in temperature in certain of the bales of wool experimented upon by the Wool Fires Commission,¹ Nos. 6 and 12, which were slipe wools. The reports by Mr. R. J. Friswell and Dr. J. S. Haldane on these experiments refer to this matter.

Mr. Friswell states:² "Another most interesting point is the fact that the oxidation of the grease by air and moisture (to which I attributed the fires on the ss. 'Gothic') is proved by these experiments. . . I have extracted the grease from Nos. 6 and 12, and have found it oxidised and rubber or varnish-like in character."

Dr. J. S. Haldane states: "The results of the tests quoted in your letter are, I think, very instructive. . . They seem to me to point to this: that the rise in temperature of the bales was due to some substance (probably an oil) capable of combining with oxygen at a comparatively low temperature, and so producing heat; that the amount of this substance is very small, since the process practically comes to an end after about a fortnight, and that more or less of this substance was present in all the bales tested."

This fatty matter has been found in greater or smaller amounts in all slipe wools examined, but the amount present, while it is undoubtedly capable of producing heat by oxidation in the presence of air and moisture, is relatively so small that even should oxidation take place the heat generated cannot be very great where the amount of foreign fatty matter is high; of course a very serious danger does exist, as, for instance, in the case of a wool containing only from 6 per cent. to 10 per cent. moisture, but from 34 per cent. to 36 per cent. foreign fatty matter of an oxidisable nature.³

SUMMARY.

The results of this investigation show that the amount of moisture which a wool can absorb from the atmosphere depends on several factors:

1. The relative humidity of the atmosphere, more moisture being absorbed during a period of high relative humidity than when the humidity is low.

2. Pure wool fibre, of which greasy wool contains from 50 per cent. to 70 per cent. and slipe wool about 75 per cent., can absorb from 18 to 20 per cent. of its weight of moisture from the atmosphere, but this amount is not sufficient to account for all the moisture absorbed by the dry normal wool fibre.

3. Natural wool fat, present in greasy wool to the extent of nearly 17 per cent., and in slipe wool to 6½ per cent., is capable of absorbing about 17 per cent. of its weight of atmospheric moisture.

4. Suint, or wool perspiration present in greasy wool to the extent of nearly 13 per cent., and in slipe wool to about 2 per cent., is very hygroscopic, and can absorb from 60 per cent. to 67 per cent. of its weight of moisture when exposed to the atmosphere.

5. Fatty matter other than natural wool fat, present in slipe wools to an amount of from two to six times that found in greasy wools, and picked up by the wool from the greasy underside of the skins during the washing process, has a retarding effect on the amount of moisture absorbed.

By thoroughly washing wool as in the case of slipe wools, not only are the incrusting and adhering matters washed out and so a less weight of the product obtained, but a further deduction in weight has to be allowed for, because the wool is incapable of absorbing the same amount of moisture from the atmosphere which it could absorb in a greasy state, before the natural fat and suint were partially removed; the amount of moisture which slipe wool can absorb from the atmosphere does not reach the legal standard of 18.25 per cent. allowed.

For permission to publish these results, the author desires to express his thanks to the Christchurch Meat Company, Limited, in whose chemical laboratory at their Islington works this investigation was carried out.

DISCUSSION.

Mr. W. H. CHARD said that the wools examined by the author of the paper were cross-bred or coarse wools, which were of more interest in New Zealand than in Australia or Tasmania, where the wool was chiefly fine or merino, only 15 to 18 per cent. being coarse. It was not the custom to slipe the wool in Australia, as in New Zealand. The Australian practice was to sweat the skin while dirty, and to thoroughly scour the wool after it was removed from the skin. In New Zealand the wool was washed while on the skin, and yielded about 75 per cent. of clean wool. The results in the paper, though interesting from a chemical point of view, were not so interesting commercially as applied to Australian wools, which were always washed again, except in the case of a few wools from Queensland, where there were artesian wells. For this reason it was not the custom to take any account of the moisture till the wool was washed, carded and combed. The short wool was washed hard, and sold as scoured, while the long fibre was combed, and sold as top. The moisture in these two was the important thing, and should be about 16 per cent., which was considered a fair thing. If there was more, an allowance was made in the price, and if there was less the price was correspondingly increased. If any chemist could discover a way of taking the burr and other woody matter out of Australian wool, or of taking the wool off the skin without staining it, this would be a matter of great importance there. There was no burr in New Zealand.

Mr. T. STEEL thought the remarks just made quite justified the need for Mr. Wright's investigations, which had thrown very much light on the subject, and he would like to see similar work done for Australian wools. He regretted there was no information supplied as to the composition of the suint.

The CHAIRMAN thought the practice of buying the raw wool without any reference to the moisture contained in it, as explained by Mr. Chard, was rather surprising and might be capable of abuse.

Mr. WRIGHT, who was unable to be present, wrote, in reply, saying that Mr. Chard's remarks scarcely touched upon the conclusions arrived at in his investigations. Practically none of the skins were "sweated" in New Zealand, the wool being removed by a depilatory, mainly sodium sulphide and lime. This treatment did not permanently discolour the skins, which were afterwards worked up clean and almost white for export; nor, if reasonable care was exercised in the use of the depilatory, was the wool stained.

Journal and Patent Literature.

PATENT SPECIFICATIONS may be obtained by post by remitting as follows:—

English.—*5s.* each, to the Comptroller of the Patent Office, C. N. Dalton, Esq., Southampton Buildings, Chancery Lane, London, W.C.

United States.—*1s.* each, to the Secretary of the Society.

French.—*1 fr. 25 c.* each, to Belin et Cie., 56, Rue des Francs Bourgeois, Paris (3e.).

German.—*1 mark* each (with full particulars) to Kaiserlich Patentamt, Berlin, Germany.

I.—PLANT, APPARATUS, AND MACHINERY.

PATENTS.

Drying cylinders. W. Kerr and T. S. Graham, Dublin.
Eng. Pat. 17,564, Aug. 21, 1908.

THE claim is for a rotating drying drum having a hollow peripheral wall, the annular space being divided into separate chambers by longitudinal ribs or partitions. Each of the chambers so formed is separately connected to the steam-inlet and exhaust chambers in the hollow trunnions by which the drum is supported.—W. H. C.

Tanks for liquids. W. P. Thompson, London. From Maschinenfabrik Augsburg-Nürnberg A. G., Nuremberg, Germany. Eng. Pat. 3788, Feb. 15, 1909.

THE side walls of the tanks are curved or bulged in a vertical plane either inwardly or outwardly, and are connected above and below to angle rings, the lower angle ring being also connected to the bottom of the tank. The walls are stiffened by compression or tension stays arranged around the periphery of the tank.—W. H. C.

Tanks of large diameter. B. E. D. Kilburn, London. From Berlin-Anhaltische Maschinenbau A. G., Berlin. Eng. Pat. 10,971, April 28, 1909.

THE lower portion of the wall, and the outer annular portion of the base, of large sheet metal tanks, such as gas-holder tanks, are strengthened and supported by being enclosed in an exterior reinforced concrete angle ring. The latter is provided with horizontal radial projections which extend beneath the tank and with vertical projections which extend upwards towards the upper edge of the tank. The relative lengths of these projections are so proportioned that the force acting on the horizontal projections is greater than that acting on the vertical projections. The tank is connected to the concrete angle ring and the projections by V-shaped metal pieces which are rivetted to the tank at one end and have the opposite end embedded in the concrete.—W. H. C.

Separating solid impurities and extraneous matter from viscous or gummy solutions. The Calico Printers' Assoc., Ltd., Manchester, and W. Browning and J. J. Barlow, Accrington. Eng. Pat. 12,739, May 29, 1909.

IN order to filter thick solutions, such as those of gum arabic or tragacanth or of Irish or Japanese moss, etc., the solutions are fed into a trough having a semi-cylindrical filter-bottom, formed of layers of suitable filtering material, and provided with a brush which is rotated in close contact with the inner side of the trough. The brush forces the liquid through the filtering medium and leaves the impurities on its inner surface. When the charge is filtered, the impurities are removed by continuing the rotation of the brush and removing the impurities from the latter by a scraper or "doctor." In some cases it is desirable to have two filters arranged one above the other, the upper serving for the preliminary and the lower for the final filtration.—W. H. C.

Separating mixed gases; Apparatus for —. C. J. A. Fiesse, Washington, D.C. U.S. Pat. 933,243, Sept. 7, 1909.

THE mixed gases are blown in puffs through fine orifices, by means of a blower and pulsator, into a downward flowing liquid column. The gases are carried downward and the portion undissolved by the liquid collects in a suitable chamber at the base of the column.—J. W. H.

Stills. Soc. Besnard, Maris, et Antoine. Fr. Pat. 398,847 Jan. 27, 1909.

ACCORDING to the present patent, a rectifying column of special construction is interposed between the condenser

and column of a distilling apparatus of the ordinary type. The liquid to be distilled passes first through the jacket of the condenser where it serves to cool the vapours from the column, and then through the rectifying column (see fig.). The latter consists of vapour chambers, 5, and liquid chambers, 4, alternately superposed. The liquid from the jacket of the condenser enters through the pipe, *a*, 1, 2, into the uppermost liquid chamber, 4, from which it overflows by the pipe, 8, into the second liquid chamber, 4, and so on to the distilling column. The pipes, 8, pass through the intermediate vapour chambers, 5. Any vapour given off in the liquid chambers, 4, passes through the annular space, *d*, into the vapour chamber next above, and any liquid condensed in the vapour chamber is prevented from entering the liquid chamber below by the cone, 9, and the upstanding pipe, 10. The condensed liquid is either re-vaporised in the vapour chamber in which it was condensed, or returns through the annular space surrounding the pipe, 6, into the vapour chamber next below. In this way the liquid flowing to the still serves to cool the vapours rising through the column without coming into direct contact with them. Any liquid condensed in the vapour chambers is gradually re-vaporised without being mixed with the liquid flowing down to the still. The enriched vapours leaving the top of the rectifying column, pass to the condenser, where they are condensed by the inflowing liquid, and the condensed liquid flows from the bottom of the condenser to a receptacle.—W. H. C.

Absorbent material for conservation and manipulation of viscous substances [molasses]. Comp. Ind. des Alcools de l'Ardèche. Fr. Pat. 400,736, June 18, 1908.

THE residue from the saccharification of sawdust by acids, in the manufacture of spirit, is washed and dried until it contains less than 20 per cent. of moisture. This material is then used for absorbing viscous substances, e.g., molasses, to facilitate their storage, manipulation and transport. A mixture of 70 parts of molasses and 30 of sawdust residue is a friable product capable of being packed in bags or pressed into cakes.—J. F. B.

Wood sawdust, etc.; *Treatment of —, for conversion into absorbent materials for viscous substances.* Comp. Ind. des Alcools de l'Ardèche. Fr. Pat. 400,737, June 18, 1908.

SAWDUST or similar material is treated with 2–4 per cent. of its weight of sulphuric acid, suitably diluted with water. The mixture is then heated at a temperature of 75–80° C. until the bulk of the water is evaporated. The acid then begins to act on the wood and this action is regulated to any desired extent by continuing the heating. Generally it is sufficient to continue the treatment until the mass assumes a deep brown colour, but by longer heating or by increasing the temperature, the wood may be converted into a dense form of charcoal. The action is stopped either by cooling or diluting with water, and the absorbent product is washed, if desired, and dried for use.—J. F. B.

Evaporator; Cast-iron — having Field tubes. G. Sanerbreys Maschinenfabr. A.-G., Stassfurt, Germany. Eng. Pat. 28,520, Dec. 31, 1908. Under Int. Conv., Jan. 4, 1908.

SEE Ger. Pat. 207,478 of 1908; this J., 1909, 465.—T. F. B.

Drying and grinding materials; Apparatus for —. G. Suter, Assignor to Soc. Chem. Ind. in Basle, Basle, Switzerland. U.S. Pat. 932,727, Aug. 31, 1909.

SEE Eng. Pat. 9741 of 1907; this J., 1908, 12.—T. F. B.

Drying grains, cement, chemicals, minerals, and other moist materials; Machine for continuously —. J. Black, A. H., H., and A. B. Lennox. Fr. Pat. 398,782, Jan. 6, 1909.

SEE Eng. Pat. 1455 of 1908; this J., 1909, 234.—T. F. B.

Sorting different substances; Process and apparatus for —. C. Seck. Fr. Pat. 398,744, Jan. 23, 1909.

SEE Eng. Pat. 4684 of 1909; this J., 1909, 591.—T. F. B.

ERRATUM. This J., Sept. 30, 1909, page 771, col. 2, line 34 from top, for "Willan" read "Willbur."

II.—FUEL, GAS, AND LIGHT.

Coal dust experiments. Times Eng. Suppl., Sept. 29, 1909. [T.R.]

THE experiments of the Mining Association of Great Britain, which were resumed at Altofts Colliery, near Normanton, on September 23 and 24, were carried out with complete success. They demonstrated both the explosiveness of coal dust by itself and also the utility of a mixture of stone dust and coal dust in limiting the area of an explosion. A space of 367 ft. in the experimental gallery—which is altogether 895 ft. long, part of it being 7½ ft. in diameter and the remainder 6 ft.—was treated with coal dust which was laid on the floor and on wooden shelves. Props were fixed and bars were set in the gallery, exactly as is the case underground. A current of air was then forced through the tunnel by means of a large ventilating fan. A small cannon was fired electrically, for the purpose of raising the dust, and two seconds afterwards a larger cannon was fired in a similar manner. The second flame ignited the dust, and an explosion of terrific force followed. A red flame leaped from the mouth of the gallery and reached to a distance of about 170 ft. beyond the entrance, while a dense cloud of smoke obscured everything. The spectators surveyed the scene from the pit bank, half a mile away, and subsequent examinations showed conclusively the force of the explosion, the woodwork in the gallery having been hurled about in a tumultuous manner. An ordinary corve which had been left inside was blown to pieces, the only recognisable portion of the woodwork being found 320 ft. away, while the metal wheels were thrown a distance of over 400 ft. The Mining Association is preparing a report on the experiments, which will be issued in a few months.

The object of the second day's experiment was to show the value of stone dust as an agent for considerably reducing, if not entirely eliminating, the danger of an

explosion of coal dust. The zone of coal dust in the gallery—which covered the same distance as on the previous day—was bounded by two zones of stone dust, one of then 100 ft. long and the other 125 ft. The explosion, which was created in the same way as on Thursday, was of immense force, but a striking difference was that only a cloud of smoke was discharged from the mouth of the gallery and no flame. Subsequent examination of pieces of gun cotton and cotton wool fixed at short intervals in the gallery showed that the flame from the coal dust had only extended forward for a distance of 39 ft., and backward—with the air current—55 ft. The effect of stone dust was thus conclusively established. The dust was obtained from an ordinary grey bind, ground into rough powder by means of a mortar mill. It was composed chiefly of silica and iron oxides, and it has been suggested that any similar inert matter will have the same effect. It is not necessary, in order to quench the flame, that something generating carbon dioxide should be used. About 15 lb. of coal dust was spread over each lineal yard of gallery.

The system of distributing stone dust in the actual workings of the mine has been adopted at Altofts, and on a road 7 ft. high, 10 ft. wide, and with a perimeter of 24 ft. this has been done at a cost of a penny per yard. The endeavour has been to distribute the dust in such a manner that it would be most easily displaced by the air currents.

Although mining engineers in Yorkshire have now accepted it as a fact that coal dust, in certain circumstances, is a violent explosive, yet there is still some scepticism in parts of South Wales. The result of the second day's experiment was to convince at least one managing director of an important Welsh colliery, but it is reported that in South Wales generally the old idea is still held that gas, and not dust, is the real explosive danger. One result of the experiments is the discovery that 1 lb. of coal dust, when heated to 1650 deg. F., gives off 43 cubic feet of gas. It is therefore suggested that gas may play some part in an explosion of dust, although the firing of the dust in the first instance is the cause of the devastation. Dr. Wheeler the resident chemist at Altofts, has prepared an interesting series of figures with regard to the effect of stone dust. It has been demonstrated that when coal dust is distributed in an atmosphere to the extent of .2 oz. per cubic foot, an explosion may take place, but there is no risk of explosion when a mixture of 90 per cent. of coal dust and 10 per cent. stone dust is diffused in the same proportion. When the quantity of coal dust in the atmosphere is .4 oz. per cubic foot, a mixture of 20 per cent. of stone dust with 80 per cent. coal dust is similarly effective.

An interesting point concerning the use of stone dust in the actual workings of the Altofts colliery is that its greater weight has the effect of removing any coal dust which there may be on any ledge, and so causing it to be either deposited on the floor, where it can easily be removed, or carried forward with the air, either out of the pit by the upcast shaft or to some other resting place, from which it will be again dislodged. The dust is merely thrown at the sides and roof of the colliery roads by two or three lads.

Peat industry of Canada. Engineering, Sept. 17, 1909. [T.R.]

AMONG the many large peat bogs existing in the more populous parts of Canada, are the Mer Bleu Bog, situated about 8 miles from Ottawa, Ontario, with an area of about 5000 acres; the Alfred Bog, situated about 40 miles from Ottawa, with an area of about 6800 acres; the Welland Bog, 6 miles north of the town of Welland, with an area of about 4900 acres; the Newington Bog, about 40 miles from Ottawa, on the New York and Ottawa Railway, with an area of about 3800 acres; the Perth Bog, about 1½ miles north of the town of Perth, with an approximate area of 2800 acres; and the Victoria Road Bog, close to Victoria Station, on the Midland Division of the Grand Trunk Railway, with an area of about 67 acres. These bogs vary considerably in average depth. For instance, in the Mer Bleu Bog there are 1564 acres with an average depth of 2.9 ft., and 347 acres with an average depth of 16 ft.; whereas in the Alfred Bog, which is rather larger

n area, there are 1377 acres with an average depth of 3 ft. 10 in., and 1014 acres with an average depth of 16.5 ft. In some of the bogs the depth in parts exceeds 20 ft. In all the peats taken from the bogs mentioned, the chemical constituents do not vary greatly in samples that are classed as absolutely dry. The volatile matter ranges from about 66 per cent., to over 70 per cent., and the carbon from about 24 to 27½ per cent., while the amount of ash obtained from different samples ranges from about 4 to 13½ per cent., the latter figure being very high, and only being reached in one sample taken from the Perth Bog. The average percentage of ash in the Mer Bleu Bog appears to be considerably higher than in any of the other bogs. On the whole, however, the percentage of ash is not excessive. The percentage of fixed carbon is comparatively regular, being an average of about 25 per cent. The calorific value of the fuel is in some cases as high as 4000 B.Th.U. per pound, and slightly over, but the average value appears to be about 8700 B.Th.U.

The Canadian peat-bogs are formed of vegetation, or the most part identical with that found in European bogs, but consisting chiefly of sphagnum and brynum mosses. None of these bogs are bare, the most open of them being covered in a great part with shrubs. The only rees characteristic of these bogs are the black spruce and the tamarack, though on the margins of most bogs, and in some of the old bogs where drainage is good, cedar, hemlock, balsam, and ash are found.

In Winnipeg the poorest quality of wood now costs from 6 dols. to 8 dols. per cord, and the price of coal is 0½ dols. per ton. The growing scarcity of wood in many parts of the Dominion, and the steady increase in the cost of coal, are bound before very long to bring this question of peat prominently forward. So far, however, very little success has been attained, although plants have been erected which were intended for the manufacture of peat briquettes, and large sums of money have been expended in this direction. The most successful method adopted up to the present time appears to have been that of A. Dobson, of Beaverton. This plant has, however, during the last season produced nothing. The only

easy to carry out this process regularly, as the amount of moisture in the peat varies considerably, and there is great irregularity in the quality of the briquettes made, some being hard and very solid, while others easily fall to pieces and form a large percentage of dust.

The Government of Canada are endeavouring to assist in the exploitation of the peat industry, and have carried on an investigation, the results of which have appeared in a Bulletin of the Department of Mines. The work was carried out by Mr. Erikhyström in 1908. The system adopted in the investigation of certain bogs was to run lines at intervals over the surface about 1000 ft. apart, and drillings were made along each of these lines at intervals of 500 ft., samples of the peat from each drill-hole being collected. In the larger bogs, drillings were made sometimes farther apart than 1000 ft. It is now proposed to establish an experimental plant where peat fuel can be manufactured on a practical scale, and where those interested may learn how to work a bog with the best chance of obtaining satisfactory fuel from it. The extraction of moisture by air-drying is too uncertain ever to be really satisfactory, and this is the method that has been mostly adopted in Canada. Ordinary processes of artificial drying are too expensive, and it is suggested that the only possibility along this line is the employment of vacuum apparatus, although it is not evident how this could be attended with economy. The elimination of water by ordinary mechanical pressure down to below 70 per cent. has been found to be impossible, owing, as pointed out by Ekenberg, to the presence of slimy hydro-cellulose. This hydrocellulose may be destroyed by a process of wet carbonisation; after which the water can be easily pressed out, the resulting briquette fuel having very nearly as low a percentage of moisture as the best air-dried peat.

Gas and coke; Production of — in the United States in 1908. E. W. Parker. Mineral Resources, 1908. [T.R.]

THE quantity and value of gas and coke made in the United States in 1907 and 1908 was as follows:—

Gas.

	1907.		1908.	
	Quantity 1000 c. ft.	Value \$.	Quantity 1000 c. ft.	Value \$.
<i>Coal-gas:</i>				
Made in gas works and by-product coke ovens	58,242,548	36,462,304	56,944,669	37,227,901
Made in retort ovens	20,516,731	3,130,839	16,205,925	2,557,483
<i>Oil and water-gas</i>	102,139,875	90,173,112	110,237,203	96,343,221

plant in operation during the last season was that of Messrs. Milne and McWilliam, at Dorchester, near London, Ontario. In connection with this the surface of the bog is harrowed by means of a common harrow drawn by a horse. The peat is then exposed to the air and sun, and left partially air-dried, after which, by means of a centrifugal pump mounted on an electrically-drawn car, moving on rails laid on the bog, the upper layer is collected and placed in another car, which runs on the same rails. The suction-pipe from the centrifugal pump can, by means of a flexible joint, be swung out at a greater or less distance from the track, by which means a considerable area of ground is covered. Before being placed in the briquetting press the peat is dried; but it has been found not at all

Of the coal gas produced, about 57 per cent. was used for illuminating, about 37 per cent. for fuel purposes, whilst the remainder is "unaccounted for." About 70 per cent. of the oil- and water-gas was used for illuminating, about 23 per cent. for fuel, and the remainder was not accounted for. The number of coal-gas companies reporting production in 1908 was 506, against 516 in 1907; 552 water- and oil-gas companies reported in 1908, against 520 in 1907.

The quantity of coal used at gas works in 1908 amounted to 3,553,920 short tons, at by-product coke plants to 5,699,058 tons, and at beehive plants 33,741,779 tons. The production of coke was as follows:—

	1907.		1908.	
	Quantity short tons.	Value \$.	Quantity short tons.	Value \$.
Gas works	2,510,106	7,667,487	2,051,899	7,041,616
By-product	5,607,899	22,665,157	4,201,226	14,465,429
Beehive	35,171,665	88,873,969	21,832,292	48,018,554

There were 4007 by-product ovens in the United States in 1908, of which 3679 were active; the figures for 1907 were 3892 and 3811 respectively. There were 84,619 active beehive ovens in 1908. The average production amounted to 1142 tons of coke for each retort oven, and 258 tons per beehive oven. The number of coke plants in 1908 was 551, a decrease of one from 1907; of these, 421 were active.

PATENTS.

Peat and the like: Briquetting of carbonised — M. Ekenberg, London. Eng. Pat. 12,010, May 21, 1909.

CARBONISED peat obtained by the wet carbonising process (Eng. Pats. 10,834 and 20,420 of 1903; this J., 1904, 14) and which has been dried thoroughly, does not bind satisfactorily in the briquetting operation as usually carried out. According to the present patent, the dried carbonised material is subjected to pressure at a temperature above 120° C. in a high-pressure briquetting press, or it is heated to 120° C. in a closed dryer and immediately pressed hot in an open-die high-pressure briquetting press.—J. W. H.

Coke ovens; Regenerative and non-regenerative — R. F. F. Fabry, Chesterfield. Eng. Pat. 8920, April 15, 1909.

IN coke ovens heated by an intermittent gas supply (Eng. Pat. 5801 of 1908; this J., 1908, 970), the combustion flues are constructed so that their cross-sectional area gradually increases from the burners to the exit ends. The tapering form of the ordinary coking chamber facilitates the arrangement, the flues being horizontal, and connected with all the burners at their narrow ends and having outlets at their wide ends.—J. W. H.

Coking ovens. S. B. Sheldon, Buffalo, N.Y. U.S. Pat. 933,349, Sept. 7, 1909.

THE oven, rectangular in form, has its upright heating flues arranged in three groups, each group being connected with a separate combustion chamber and regenerator. The area of the flues and the capacities of the combustion chamber and regenerator of the middle group are equal to the combined area of the flues and the combined capacities of the combustion chambers and regenerators of the other groups.—J. W. H.

Coke-oven; Regenerative — L. Bansart. Fr. Pat. 398,843, Jan. 27, 1909.

EACH oven is provided with four regenerator chambers arranged in pairs on each side of the central line of the battery of ovens. Each pair of regenerators, which are placed one above the other, below and parallel to the oven, is worked independently, being connected to the heating flues of that half of the oven immediately above. The air for combustion and the waste gas are passed alternately through each chamber. In this way the alternate heating and cooling of opposite sides of the battery of ovens and the consequent unequal strains on the brickwork are avoided.—W. H. C.

Doors for retorts, coke ovens and other furnaces. F. Shaw, T. M. Percy, and J. K. Entwistle, Wigan. Eng. Pat. 17,647, Aug. 22, 1908.

THE doors of retorts, ovens and other furnaces are formed with channels, so that by means of bridge-pipes, hot gases from the main flues may be made to circulate through them and ensure regular heating of the whole charge in the apparatus.—J. W. H.

Ovens, retorts, etc., for the carbonisation of coal; Process for preventing destruction of the walls of — H. Koppers. Fr. Pat. 400,648, Mar. 10, 1909. Under Int. Conv., Mar. 11, 1908.

THE charge is mixed with a quantity of silica sufficient to combine with the alkali salts contained in the ash, so that these alkali salts are prevented from volatilising and attacking the silica in the walls of the oven or retort. The silica may be used in the form of sand.—A. T. L.

Gas producer plants primarily designed for the recovery of ammonia; Recovery of certain by-products in — W. J. Crossley and T. Rigby, Manchester. Eng. Pat. 17,978, Aug. 27, 1908.

THE patent relates to gas-producer plants of the Mond type or of the type described in Eng. Pat. 24,144 of 1907 (this J., 1907, 957), and to a process for recovering the acetic acid which is present in the gases in considerable quantities when peat and similar fuels are used in the producer. The acetic acid is caused to be held in solution in the sulphate liquors intended for concentration, and recovered from the vapours during concentration in a suitable manner. In the Mond plant, the process is carried out by circulating the liquor from the mechanical gas washer, which contains ammonium acetate, through the acid tower, so that the whole of the acetic acid is collected in the sulphate liquor from this tower. The preferred method of recovering the acetic acid from the vapours given off during the concentration of the sulphate liquor consists in mixing these vapours with the air from the saturating tower and washing the mixture with an alkaline liquor, such as milk of lime or soda, before it reaches the superheater. The alkaline liquor used for this purpose is circulated through a jacket around the gas outlet pipe of the superheater. A recovery of waste heat is effected by this process and the air for the producers which is leaving the saturating tower is saturated at 73° C. saturated at 80° C. after passing through the alkaline washer, so that less steam is required from outside sources.—A. T. L.

Gas producers; Grates of — W. A. Bone, Leeds, and R. V. Wheeler, Altofts, Yorks. Eng. Pat. 10,230 of 1909; date of application, Oct. 29, 1908.

THE invention relates to means for supporting the grate bars in grates of inverted conical form. A series of outwardly projecting studs is fixed to the lower end of the shell of the producer, and the grate bars are provided with holes near the upper end and are hung on the studs and secured by cotter-pins. Alternatively, the bars are passed up through holes in an angle-iron ring fixed to the shell of the producer, and are secured by cotter-pins passing through the bars. The lower ends of the grate-bars rest loosely on a fixed ring.—A. T. L.

Lighting gas [and coke]; Manufacture of — A. L. H. Biennaimé and A. Requier. First Addition, dated June 15, 1908, to Fr. Pat. 394,311, Nov. 22, 1907 (this J., 1909, 197).

THE process described in the principal patent is modified by distilling at a low temperature, and stopping the distillation before all the volatile substances have been liberated, in order to prevent the briquettes from caking or from changing their shape. The escape of volatile products from the briquettes during distillation is facilitated by adding coke, anthracite or non-bituminous coal, sawdust, cut straw, etc., to the fuel before briquetting.—A. T. L.

Liquefied gas for lighting; Manufacture of — from distillation gases. H. Blau. Fr. Pat. 398,839, Jan. 27, 1909. Under Int. Conv., Jan. 31, 1908.

DISTILLATION gases are compressed and cooled to atmospheric temperature, and the hydrocarbons which liquefy under these conditions are collected. The remaining gas is then highly compressed so as to liquefy all but the permanent gases present, and the liquid is stored in steel bottles. The liquid hydrocarbons collected in the first part of the process contain dissolved gases of considerable illuminating power, and to recover these gases, the vessel in which the liquid hydrocarbons are collected is placed in communication with the inlet of the compressor.—A. T. L.

Gas for engines; Plant for the production of — H. Pettibone. Fr. Pat. 398,848, Jan. 27, 1909.

THE plant, which is suitable for use with marine engines, comprises two producers and condensers connected to a single washing and purifying plant. The producers are fed with bituminous coal, anthracite, coke, peat, or

wood, and work with a down-draught, the gas being drawn from the lower ends of the producers and delivered through a pressure-regulating valve to the engine by means of water-jet ejectors arranged at the outlet of the condensers, or by a mechanical exhauster arranged at the outlet of the scrubber. In order that the quality of the gas may not vary, the output of the producers is kept constant, the excess of gas when the engine is not under full load escaping through a branch-pipe between the scrubbers and the pressure-regulator. The valve controlling this branch-pipe is connected up to the engine throttle valve so as to be opened when the throttle valve is closed and *vice versa*. When the fuel column in the producer becomes clogged with clinker and ash, the working is momentarily interrupted and a blast of compressed air from a reservoir is passed up through the fuel, the combustion products escaping by way of the air inlet and a three-way cock to a vent-pipe. The condensers are of the multitubular type, and the air supply for the producers, together with exhaust gases from the engine, is drawn through the casing of the condenser so as to be heated by the gases passing through the tubes. The gas leaving the condensers passes through a washer in which it encounters a series of water-sprays, then through a centrifugal scrubber, and finally through a separator in which the gas is freed from water in suspension by means of baffle-plates.—A. T. L.

Producer working by suction or by pressure. A. Béchevot. Fr. Pat. 400,329, May 29, 1908.

The lower part of the producer chamber is formed by a cylindrical cast-iron shell, supported only at its upper edge, so that it is free to expand. A series of gutters on the outside of this shell serves for the evaporation of water, the annular chamber between the shell and the casing of the producer serving as a vaporising chamber through which the air supply for the producer is passed. The lower edge of the cylindrical shell dips into a water-trough which forms the base of the vaporising chamber. The fuel column is supported by a plate at the base of the producer, and by an inverted conical casting fixed within the lower part of the cast-iron producer chamber. When working by suction, the ash-pit doors and doors of the outer casing of the vaporising chamber can be opened for inspection and for cleaning, without interrupting the working of the producer.—A. T. L.

Producer with gas-discharge conduit at or above the fire-zone. Dresdner Gasmotorenfabr. vorm. M. Hille. Ger. Pat. 212,505, Oct. 6, 1908.

The upper part of, or a little above, the fire-zone, a gas-discharge belt or conduit is formed in the wall of the producer, this conduit being of greater diameter on the side where the gas-discharge pipe is connected, than on the other side.—A. S.

Purifying apparatus. E. Schmiedt, Aschaffenburg, Germany. Eng. Pat. 5768, Mar. 10, 1909.

The apparatus of the type in which the gas enters and passes the purifying material through *louveres* extending over the whole area of the inlet and outlet sides of the purifying chamber, vertical baffle-plates are arranged to project inwards from the ends and downwards from the roof of the purifying chamber, so that when the purifying material shrinks and settles down, the gas is prevented from passing along by the walls and roof of the purifying chamber without passing through the purifying material.—A. T. L.

Purifying gas; Apparatus for —. W. McArthur. Tenino, Wash. U.S. Pat. 933,097, Sept. 7, 1909.

The purifying apparatus is arranged at the base of a holder. The gas is made to bubble through a compartment containing milk of lime ("lime in a semi-liquid state") and then through a compartment, over the first, containing coke, sawdust, and lime.—J. W. H.

Ammonia from coal-gases; Method of recovering —. F. J. Collin, Dortmund, Germany. U.S. Pat. 932,738, Aug. 31, 1909.

The hot gases from the retorts are saturated with steam immediately upon entering the gas main, and are subsequently cooled to recover the ammonia.—W. H. C.

Electric lamps; Method for regenerating blackened carbon filament —. E. A. Krüger, Seehausen, Germany. Eng. Pat. 8283, April 6, 1909. Under Int. Conv., April 6, 1908.

The patent relates to the process in which the lamp is opened, and then heated in an open flame to burn off the carbon from the interior surface of the bulb, and in which a further deposit of carbon is then made upon the filament. The invention consists in introducing a measured quantity of a pure hydrocarbon into the evacuated bulb, after the deposit has been removed from the glass, and then heating the filament electrically so that carbon is deposited on it in the absence of air. The apparatus consists of a main connected to an air pump and provided with branches which are connected to the lamp-bulbs, to reservoirs of liquid hydrocarbon and to bulbs in which the hydrocarbon vapour is measured off. Cocks are arranged so that the lamp-bulbs may be evacuated and then charged with the requisite amount of hydrocarbon from the measuring bulbs.—A. T. L.

Coke oven walls; Method of preserving —. H. Koppers. Essen-Ruhr, Germany. Eng. Pat. 4792, Feb. 26, 1909. Under Int. Conv., March 11, 1908.

SEE Fr. Pat. 400,648 of 1909; preceding.—T. F. B.

Retorts; Vertical —. R. Dempster and Sons, Ltd. Fr. Pat. 400,685, March 11, 1909.

SEE Eng. Pat. 16,405 of 1908; this J., 1909, 647.—T. F. B.

Gas generators. A. Béchevot, Paris. Eng. Pat. 16,333, Aug. 1, 1908.

SEE Fr. Pat. 400,329 of 1908; preceding.—T. F. B.

Gas generator. G. F. Jaubert, Paris. U.S. Pat. 933,077, Sept. 7, 1909.

SEE Eng. Pat. 17,252 of 1907; this J., 1908, 797.—T. F. B.

Methane or mixtures of hydrogen and methane; Manufacture of —. P. Sabatier. Fr. Pat. 400,656, June 15, 1908.

SEE Eng. Pat. 27,045 of 1908; this J., 1909, 876.—T. F. B.

Combustion of gaseous fuels; Process and apparatus for retarding the —. R. F. F. Fabry. Fr. Pat. 400,849, March 15, 1909. Under Int. Conv., March 16, 1908.

SEE Eng. Pat. 5801 of 1908; this J., 1908, 972.—T. F. B.

Apparatus for analysing gas. Eng. Pat. 18,829. See XXIII, Apparatus.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

Water in tar; Determination of —. H. Beck. Chem.-Zeit., 1909, 33, 951–952.

The estimation of water in gas tar is usually made by distilling about 1 kilo. of the tar in a metal flask of about 2 litres capacity, until the oil distilling over is free from drops of water. The operation takes 3–4 hours, and there is always danger of the liquid frothing and thus "boiling over." The time is much shortened and the operation simplified if a given quantity of the tar is run slowly into a metal flask containing "heavy oil" heated to 250°–270° C. The rate of flow of the tar into the flask is regulated so that although vaporisation of the water is instantaneous, there is no frothing, and when all the tar has been run in, the temperature of the oil is raised to about

300° C. to drive over all water vapour. Any water remaining in the condenser tube is rinsed into the graduated receiver with a little xylol, and after standing for a short time in a warm place, the volume of water is noted. The method was tested upon known mixtures of dehydrated tar and water and gave very satisfactory results. The operation, with a 50 per cent. mixture, was carried through in about 35 minutes.—F. M.

Bibi-Eibat petroleum: Optical examination of —.
M. Rakusin. J. Russ. Phys.-Chem. Ges., 1909, **41**, 483—500. Chem. Zentr., 1909, **2**, 859—860. (See also this J., 1908, 397.)

From the known data concerning Bibi-Eibat petroleum, the author draws the following conclusions:—(1). The percentage yields of fractions distilling over equal intervals of temperature are, for corresponding kinds of crude oil, inversely proportional to the specific gravities of the oils, and hence also to the depths of the oil-yielding strata. (2). The natural oil is dextro-rotatory, the rotatory power being proportional to the depth of the oil-yielding strata. (3). There is no connection between the formation of petroleum and volcanic activity. (4). The rotatory power of the oil is due to the formation of the latter from compounds containing asymmetric carbon atoms. (5). There is a connection between the paraffin content of a petroleum oil and its age.—A. S.

The value of the imports of various coal-tar products into the United States during the last three years have been as follows:—

	1906. Value \$.	1907. Value \$.	1908. Value \$.

Tar and ammonia: Production of — in gas works and coke-ovens in the United States. E. W. Parker. Mineral Resources, 1908. [T.R.]

The following table shows the amounts and values of tar and ammonia (calculated as anhydrous ammonia) and ammonium sulphate produced in coal gas works, by-product coke ovens, and oil- and water-gas works in the United States in 1907 and 1908:—

Petroleum in Burma. Od. Paint and Drug Rep., Sept. 13, 1909. [T.R.]

The U.S. Consul at Rangoon reports as follows: The richest oil-bearing tract of Burma lies in the valley of the Irrawaddy, in Upper Burma, in the southern portion of the dry zone. Oil is still obtained from wells dug by native labour, but the principal output is from wells regularly drilled with modern machinery. The output of the

	1907.		1908.	
	Gallons.	Value.	Gallons.	Value.
Tar:		\$		\$
Coal-gas works	49,681,965	1,408,997	48,541,220	1,529,505
Coke-ovens	53,995,795	1,242,530	42,720,609	1,067,613
Oil- and water-gas works	14,414,017	342,041	14,728,033	368,741
Ammonia (anhydrous):	lb.		lb.	
Gas works and coke ovens	20,993,867	1,128,178	15,347,354	853,632
Ammonium sulphate (produced and sold):				
Gas works and coke ovens	48,882,237	1,525,472	44,093,437	1,322,807

The above figures were taken from reports of 488 companies in 1907 and 471 in 1908. The average yields per ton of coal carbonised were:—Tar: 1907, 9.04 galls.; 1908, 10.3 galls. Ammonia: 1907, 4.75 lb.; 1908, 4.7 lb.

hereditary well lessees is purchased by the refining companies at varying prices. A royalty is paid to the Government of Sd. per 100 viss (365 pounds) in the case of early leases, and Sd. per 40 gallons in later ones. A system of pipe lines has been installed. The first section

was about 45 miles in length, connecting the fields at Singu and Yenangyat with Yenangyaung, and pumping stations were installed at Singu and Yenangyat. About the same time another line was constructed to convey the oil from the tank boats to refineries. As both these lines were successful, the construction of a pipe line from Yenangyaung to Rangoon, a distance of 275 miles, was begun early in 1907, and is now completed. There are four pumping stations on this line, each connected with Yenangyaung and Rangoon by telegraph.

Oil is also produced in the districts of Kyankpyu, Akyab and Thayetmyo. Prospecting is continually going on, and there is no doubt that there are many valuable fields as yet undiscovered or undeveloped. From the Cheduba wells, in the Kyankpyu district, a thick dark-coloured oil is obtained, which is used for burning, for covering the bottom of boats, and as varnish. The amount obtained is small and the methods are primitive and wasteful. The oil produced from these wells has a low flash point (below 40° F.), while the specific gravity is 0.8247. At the present time nine companies are engaged in the extraction or refining of petroleum, with a combined capital of £4,540,000. The value of the unrefined oil produced in 1901 was £196,710, and in 1907, £583,579.

The output of the Burma oil fields is all disposed of in Burma or other provinces of India. For the three years from 1903-4 to 1905-6 a considerable amount of oil was exported, principally to the Far East. With the exception of that period the oil dealers have confined themselves to the Indian market. A considerable quantity of high-grade oil is imported into Burma, principally from the United States. In 1907-8 the imports amounted to 2,230,592 gallons, valued at £81,410, of which 2,188,442 gallons, valued at £79,338, were from the United States. Burma's trade in oil with different parts of India, excluding the trade of Rangoon and vicinity, in 1901-2 was 6,542,432 gallons, valued at £531,511, and in 1907-8 it was 69,464,772 gallons, valued at £1,443,280.

Two of the native reserves are of importance—the Twingone, about 300 acres in extent, and the Beme, containing about 160 acres. The number of private wells and well sites in these two reserves is now over 3700. Of this number, however, some 1500 have been temporarily taken over by the Government for non-observance of regulations. At present the best-known and developed field is at Yenangyaung, the average daily output being about 5,000 viss (54,750 lb.). There are newer fields which are producing oil in increasing quantities, notably at Singu and Yenangyat.

There is an increasingly large export trade in the by-products obtained from crude petroleum, such as paraffin wax and mineral oils. These exports were as follows in 1907-8:—Candles, 5,307,512 lb., valued at £97,354, of which 661,000 lb., valued at £12,000, went to the Philippines; wax, 74,205 hundredweight, valued at £109,482, of which £7000 worth went to the United States and 2400 to the Philippines.

PATENT.

cetone; Manufacture of —. A. L. A. Pagès and R. P. T. Duchemin, Paris. U.S. Pat. 933,107, Sept. 7, 1909.

Eng. Pat. 8757 of 1906; this J., 1906, 634.—T. F. B.

IV.—COLOURING MATTERS AND DYESTUFFS.

PATENTS.

colouring matter suitable for use as a pigment or lake; Manufacture of —. J. Y. Johnson, London. From Badische Anilin und Soda Fabrik, Ludwigshafen on Rhine, Germany. Eng. Pat. 17,546, July 28, 1909. Addition to Eng. Pat. 26,714, Dec. 9, 1908.

4-chloro-6-nitraniline is treated with formaldehyde, somewhat reddish yellow dyestuff is produced, which fast to light, lime, water, and alcohol. It is suitable

for use as a pigment or lake, and possesses properties generally similar to those of the dyestuff described in the principal patent (this J., 1909, 210).—T. F. B.

Disazo dyestuffs. F. Runkel and M. Herzberg, Assignors to Farbenfabr. vorm. F. Bayer und Co., Elberfeld, Germany. U.S. Pats. 932,812 and 932,813, Aug. 31, 1909.

CLAIM is made, in the first patent, for the disazo-dyestuff obtained from diazotised *o*-aminophenyl-*o*-tolyl ether, diazotised sulphanilic acid, and 1:8-aminonaphthol-4-sulphonic acid, which dyes wool in blue-black shades fast to washing and milling; and in the second patent for the dyestuff prepared from diazotised *o*-aminophenyl ether, diazotised dichloroaniline, and 1:8-aminonaphthol-3:6-disulphonic acid, which dyes wool in greenish blue-black shades fast to washing and milling.—J. C. C.

Galloguanine series; Production of new dyestuffs of the —. Farbenfabr. vorm. F. Bayer und Co. First Addition, dated Feb. 23, 1909, to Fr. Pat. 396,564, Nov. 20, 1908.

In the example given in the chief patent (this J., 1909, 595), nitrosodiethylaniline may be substituted for nitrosodimethylaniline.—J. C. C.

Anthracene series; Production of dyestuffs of the —. Farbenfabr. vorm. F. Bayer und Co. Fr. Pat. 400,653, Mar. 10, 1909. Under Int. Conv., June 4, June 9, and Aug. 28, 1908.

NEW dyestuffs of the anthracene series are obtained by treating aminoanthraquinones or their derivatives, analogues or homologues with agents capable of introducing the benzoyl or a substituted benzoyl group into the amino-group. Example: A mixture of 10 parts of 1-aminoanthraquinone, 100 parts of nitrobenzene, and 20 parts of benzoyl chloride is boiled for half an hour. The benzoylaminoanthraquinone produced crystallises on cooling and is collected and dried. With alkaline hyposulphite (hydrosulphite) a vat is obtained from which cotton is dyed in yellow shades. A list of dyestuffs of this class is given in the patent together with the shades produced on cotton, wool, and silk. The dyestuffs may also be used in printing.—J. C. C.

Black colouring matter for applying to textiles; Production of a —. F. L. P. Bertrand. Fr. Pat. 400,743, June 20, 1908.

THE black colouring matter is obtained by heating a mixture of sulphuric acid, iron sulphide, naphthalene, aniline, and copper nitrate to 100° C. The proportions of the different constituents are varied from 10 to 25 per cent. according to the intensity of the black desired. The colouring matter can be applied cold.—S. H. H.

Dyestuffs by melting phthalic acid with phenols, naphthols, or aromatic bases; Process for preparing —. E. Ziegler. Ger. Pat. 212,796, May 20, 1906.

PHTHALIC acid or anhydride is melted with phenols, naphthols, or aromatic amines, and fatty or aromatic aldehydes, ketones, or substances containing aldehydes or ketones (e.g., essential oils), or aromatic alcohols or nitro-compounds. The aldehydes, etc., may be added to the mixture before or during melting, or the product may be treated with them subsequently. Examples are given in which 1 mol. of phthalic acid, 2 mols. of resorcinol, and 1 mol. of either benzaldehyde, or nitrobenzene, or benzyl alcohol are heated together. The shades of the resulting dyestuffs are said to be quite distinct from those produced from phthalic acid and the phenols or bases alone.—T. F. B.

Vat dyestuff; Process for preparing an orange —. Ges. f. Chem. Industrie in Basel. Ger. Pat. 212,858, Jan. 10, 1908.

By condensing acenaphthenone with acenaphthenequinone, with or without the use of condensing agents, a product is obtained, which is probably identical with the biacenaphthylidene-dione, formed in small quantities when acenaphthene is oxidised or acenaphthenequinone reduced.

It is reduced by alkaline solutions of hydrosulphite, forming violet solutions, in which, when diluted, un mordanted cotton is dyed orange-yellow shades.—T. F. B.

Basic dyestuffs; Manufacture of —, P. A. Newton, London. From Farbenfabr. vorm. F. Bayer und Co., Elberfeld, Germany. Eng. Pat. 21,585, Oct. 12, 1908. Addition to Eng. Pat. 20,367, Sept. 28, 1908.

SEE Addition of Nov. 23, 1908, to Fr. Pat. 395,793 of 1908; this J., 1909, 595.—T. F. B.

Azo dyestuffs; Manufacture of —, P. A. Newton, London. From Farbenfabr. vorm. F. Bayer und Co., Elberfeld, Germany. Eng. Pat. 25,816, Nov. 30, 1908.

Wool and cotton; Determination of — in mixtures. B. Ruzskowski and E. Schmidt. Chem.-Zeit., 1909, 33, 949—950.

THE chemical methods for the estimation of wool in the presence of cotton are based upon the solvent action which warm caustic soda exerts upon wool. The best method is perhaps the official one in use at the Conditioning

House at Aachen, according to which the material is treated with a volatile solvent to remove fatty matter and then with hydrochloric acid (2 per cent.) to remove filling materials. It is then well rinsed and dried at 110° C. The wool is removed by boiling in a 2 per cent. caustic soda solution and the residual cotton is rinsed, lightly soaped, rinsed again until free from acid, and dried at 110° C. The proportion of wool to cotton is calculated from the dry weights, allowance being made for the facts that cotton itself loses some 3.5 per cent. by boiling with caustic soda, and scoured wool rinsed thoroughly in water loses about 1 per cent. The authors think that such methods as the above have serious drawbacks and have sought to use the nitrogen content of wool as a basis for the analysis. The nitrogen estimation (Kjeldahl) of scoured wool (loose, as yarn, and in the piece) and of woollen yarn dyed in various shades gave results varying between 13.81 and 14.14, with a mean for all analyses of 14.02 per cent. of nitrogen. Analyses of mixed fibres were made simultaneously by this and the Aachen method and the results are in general in close agreement; the nitrogen method in all cases gives a slightly higher percentage of wool than is shown by the other.—F. M.

Wild silks; Hydrolysis of certain —, U. Suzuki, K. Yoshimura, and R. Inouye. J. Coll. Agric., Imp. Univ., Tokyo, 1909, 1, 59—75.

THE authors have investigated three species of Japanese wild silk, viz.: "Sakusan" (*Anthera Pernyi, Guér.*), "Yamamai" (*Anthera Yamamai, Guér.*) and "Kuriwata" (*Caligula Japonica, Moore*). The raw silks were boiled for 2 days with concentrated hydrochloric acid under a reflux condenser and the products of hydrolysis (amino-acids and bases) were investigated. Ordinary *Bombyx* silk was treated in a similar manner for comparison. The principal results are summarised in the table below:—

Species of silk.	"Bombyx" (raw silk).	"Sakusan" (raw silk).	"Yamamai" (raw silk).	"Kuriwata" (raw silk).
Moisture, per cent.	12.90	13.16	11.29	11.71
Dry substance, per cent. . .	87.10	86.84	88.71	88.29
100 parts of dry substance yielded:				
Ash	0.63	2.92	4.73	3.85
Soluble in boiling hydrochloric acid	99.14	92.21	97.07	88.34
Insoluble in boiling hydrochloric acid	0.86	7.79	2.93	11.66
Total nitrogen	18.98	18.87	17.73	16.73
Nitrogen soluble in hydrochloric acid	18.86	16.39	17.26	15.77
Ditto insoluble in hydrochloric acid	0.12	2.48	0.47	0.96
100 parts of the total nitrogen showed:				
Nitrogen soluble in boiling hydrochloric acid	99.34	86.87	97.34	94.26
Ammonia nitrogen	4.57	2.52	3.85	4.08
Nitrogen precipitated by phosphotungstic acid ...	1.78	13.11	19.44	15.54

PATENTS.

Cellulose compounds in definite shapes [threads, films, &c.]; Manufacture of —, L. Lederer, Sulzbach, Germany. Eng. Pat. 11,625, May 17, 1909. Under Int. Conv., July 3, 1908.

ARTIFICIAL threads spun from solutions of cellulose and nitro- or acetyl-cellulose differ in their behaviour towards water and dyestuffs. Cellulose threads are readily dyed, but lose in tensile strength by the absorption of water. The cellulose esters on the other hand are not affected by water but do not easily take up dyestuffs. The advantages of the products may be combined by pro-

ducing a mixed thread of nitro- and acetyl-cellulose and then denitrating, the resulting thread being easily dyed and possessing good strength even in the moist condition. The solution for spinning is prepared by dissolving 6 parts of trinitrocellulose and 2 parts of triacetylcellulose in 27 parts of acetone and 16 parts of acetylene tetrachloride. The solution is homogeneous, even though acetylcellulose is not dissolved by acetone alone and nitrocellulose is insoluble in acetylene tetrachloride. Filaments are produced from the mixed solution by precipitation with alcohol. Films may be made in a similar manner, and these, by denitration do not change their external appearance; they take up dyestuffs easily, are quite transparent, and on account of their low degree of inflammability may with advantage replace celluloid films in photography and similar industries.—F. M.

Artificial silk: Coagulation of fibres of —. Pinel Frères.
Fr. Pat. 400,577, June 11, 1908.

THE coagulating liquid described, is particularly applicable for the coagulation of fibres of "viscose" or other alkaline solutions of cellulose. The solutions previously used for the purpose were either neutral or acid solutions of mineral salts; they had the disadvantage, that the salts were apt to crystallise out. According to the present patent, an acid solution containing an organic substance, e.g., glucose, which does not crystallise readily, is used. The following bath is recommended: 30 grms. of glucose, 15 grms. of sulphuric acid of 66° B., and 55 grms. of water.

—S. H. H.

Fibrous materials: Manufacture of —. J. T. Wood.
Assignor to J. W. Wilson, Philadelphia, Pa. U.S. Pat. 931,979, Aug. 24, 1909.

THE fibrous material is treated in a hot bath of zinc chloride, or zinc chloride and oil. The mass, after removal from the bath, is allowed to cool and set, and after heating in a chamber to remove absorbed moisture, is washed with water until free from zinc chloride.—F. M.

Fabrics: Treatment of —. O. Heimann, Erfurt, Germany. Eng. Pat. 2313, Jan. 30, 1909.

THE fabric is led slowly over and under a series of rollers arranged in the top and bottom of a large chamber containing a very moist atmosphere. In order to prevent moisture from condensing and falling on to the material, the ceiling of the chamber is heated. By the time the fabric has travelled through the chamber, the fibres have regained their original elasticity (lost during the process of manufacture) and the material has become suitable for sewing.—P. F. C.

Silk: Degumming, bleaching and dyeing of —. Schmid Frères. Third Addition, dated March 30, 1908, to Fr. Pat. 345,173, July 27, 1904 (this J., 1905, 24; 1906, 475).

THE machine consists of a vat containing a small quantity of the liquor with which the silk is to be treated. Steam pipes placed at the bottom of the vat cause the liquor to froth up, thus filling the upper part of the vat with froth. The sides of the vat are made to admit four separate endless sheets, which pass through the vat out to the opposite side and round again. Where the sheets enter and leave the vat, there is an inclined covering to stain the froth. The silk is placed on the cloths and kept in position while in the vat by passing between horizontal boards. In a modified form of apparatus, no outside coverings are used to retain the froth, the cloth being led directly into the vat. It first enters a small outer compartment, which contains steam pipes and thus serves to produce an abundance of froth; the cloth enters the vat. In a third modification, the cloth is made to enter the vat from above, being slightly inclined downwards over a large distance, to pass through the froth and then out again at a slight upward inclination. In this machine, the silk is treated continuously, being received on the cloth at one side and discharged at the other side.—S. H. H.

Catechin and catechu-tannic acid: Process for preparing a condensation product of — [for silk reeling, &c.]. Fabr. de Couleurs d'Aniline et Extraits ci-dev. J. R. Geigy. Fr. Pat. 401,108, July 7, 1908.

By heating catechin with catechu-tannic acid, either in their natural form (as Gambier extract) or in the same proportions as they occur in Gambier (64:163), for several hours at 100° C. or higher temperatures, brownish red liquid or solid condensation products are produced, which possess great affinity for silk weighted with tin: for example, pure Gambier, after heating for two hours at 110°–115° C., produced an increase of weight of 95 per cent., compared with 14 per cent. with pure Gambier unheated, both being from solutions of 7° B. The products may also be used in tanning.—T. F. B.

Preparing, dyeing, or otherwise treating with liquids, wool, yarn, or other fibrous material; Apparatus for —. J. Rhodes, Bradford. Eng. Pat. 17,083, Aug. 14, 1908.

AN inner vessel, which is divided into several compartments, fits into an outer one, so that there is a space left between the two. The material to be treated, is placed in the compartments of the inner vessel and the necessary liquors are sprayed over it from sprinklers placed above. The flow of the liquor to any portion of the material may be regulated by sliding doors placed beneath the sprinklers, and by baffle-plates (which may be set at any desired angle) arranged in the space between the two vessels.

—F. M.

Vats for dyeing and like purposes. J. Dean, Bradford. Eng. Pat. 6486, Mar. 18, 1909.

IN vats in which the material is dyed in rope form and which are heated by means of steam pipes, the latter have usually to be "guarded" to prevent the goods being damaged by contact therewith. This causes a loss of space and irregularities in the circulation of the dye-liquor. In the improved vat the steam is blown into a channel or trough, formed by a partition which is carried up into the vat at a short distance from the outer wall. The hot liquors are discharged from this over the goods, and flow through a perforated grating which is placed over the recess in the base of the vat, in which the steam injector is placed.—F. M.

Dyeing fabrics in the open width: Apparatus for —. A. Duverger and A. Henrion. First Addition, dated March 10, 1909, to Fr. Pat. 392,693, July 25, 1908 (this J., 1909, 19).

OPEN pipes are placed in the dye-bath, one near the wall at one side of the bath and the other in the middle between the partitions contained in the bath. These pipes contain steam injectors which are placed at the bottom of the dye-bath and force the dye-liquor up the pipes and against baffle-plates at the upper extremities.—S. H. H.

Dyeing of variegated shades on wool. E. P. J. Roussel. Fr. Pat. 400,588, Feb. 10, 1909.

WOOL after bleaching has a different affinity for dyestuffs than it has in the raw state: the unbleached wool is dyed a heavier shade not so pure as that of the bleached variety. By mixing the unbleached and bleached wool in varying proportions throughout a fabric and dyeing the product, gradations of colour can be obtained, the shades varying as desired from a heavy to a bright shade of the same colour.

—S. H. H.

Calico printing. Calico Printers' Association, Ltd., and F. Davis, Manchester. Eng. Pats. 17,713, Aug. 24, 1908, and 2437, Feb. 2, 1909.

THE patents relate to certain novel effects in indigo printing. The material may or may not be previously prepared with glucose, but is printed with a resist containing sulphur and a dyestuff of the sulphide, thioindigo, or indanthrene class. A suitable indigo printing colour (containing alkali) is then applied and the cloth is aged, steamed, washed, and otherwise treated in the usual way. The presence of sulphur prevents the fixation of the indigo upon the parts printed with the resist, but under

the influence of the sulphur and alkali, the dyestuff in the resist is reduced and fixed. The most suitable resist colours are obtained with the sulphide dyestuffs, but Thioindigo Red, Indanthrene Yellow G, (and R), Indanthrene Brown, Algol Dark Green B, and Ciba Violet may be used. For "cover" colours almost all of the vat dyestuffs are suitable.—F. M.

Colour effects on textile fabrics; Process for producing —.

Farbw. vorm. Meister, Lucius und Brüning, Höchst a M., Germany. Eng. Pat. 6876, Mar. 22, 1909. Under Int. Conv., Mar. 27, 1908.

VARIATED, marbled or veined effects in two or more colours have recently been produced upon paper whilst this is still in the web, and paper showing relief colour effects (resembling natural patterns or regularly arranged figures) has also been produced. Hitherto, similar effects have not been produced upon textiles, but it is now found that the effect produced by suitable means (spraying of dyestuff solutions, resists, discharges, dye-components, etc.) upon the paper web, may be transferred to fabrics composed of silk, wool, cotton, jute, or other fibre, by bringing the fabric into intimate contact with the paper whilst this is still in the wet or moist condition. In many cases it is sufficient to pass the combination between pressing rollers, or place, in layers, in a hydraulic press for the necessary length of time. The transference and fixation of the colour may be assisted by moistening or damping, or by the use of heat and steam, etc.—F. M.

Reducing agents [for use in printing]; Production of new —. A. Ashworth, Bury. Eng. Pat. 19,528, Sept. 17, 1908.

NEW and relatively stable reducing agents are manufactured, in paste form, by mixing zinc dust with a concentrated solution of British gum, dextrin, molasses, gum tragacanth, gum arabic, gum sengal, or sugar, with or without the addition of calcium chloride or zinc chloride, and treating the mixture with sulphur dioxide at a suitable temperature. For example, into a well-stirred mixture of 20 lb. of zinc dust, 15 of molasses (or sugar), 2 of water, and 20 of a solution containing 45 per cent. of calcium chloride (or zinc chloride), 27 lb. of sulphur dioxide are introduced, until the zinc dust has disappeared, the temperature being maintained at 40°–50° C.; or, the mixture to be treated with the gas may consist of 20 lb. of zinc dust and 30 of dextrin solution, made by dissolving 15 lb. of dry dextrin in 15 lb. of water, or 15 lb. of 45 per cent. calcium chloride solution. For discharging developed dyes, 90 parts of British gum, 145 of water, and 10 of brown glycerin are boiled together, and 55 parts of sodium chloride solution (60° Tw.) are added, the temperature being thereby reduced to about 130° F.; then 170 parts of the reducing agent and 20 of sodium bisulphite solution (60° Tw.) are added, and the whole strained whilst warm; after printing, the fabric is passed through the ager for several minutes, at about 213° F. The new products have the advantage of reducing indigo and other dyestuffs at the ordinary temperature, and it is not necessary to perform either the steaming or the ageing immediately after the printing, or the clearing immediately after the steaming.—F. SOBN.

Lustrous surface on animal and vegetable fibres; Production of a —. R. Robitschek and I. de Lauverzac. Fr. Pat. 400,575, June 11, 1908.

THE fibre is first immersed in a bath containing 100 grms. of gelatin, 25 grms. of glycerin and 600 grms. of water; this bath renders the fibre capable of taking up the subsequent coating. The treated fibre is then immersed in a bath containing collodion, a solution of nitrocellulose in ether or alcohol, or a cuprammonium solution of cellulose. In order to increase the adherence of the film of collodion, etc., to the fibre, the whole is drawn through an orifice into a vessel which is used for drying the film and to bring it in contact with liquids which coagulate it. The suppleness of the fibre can be further increased by treating it with glycerin, oil, etc. The product is said to appear like a simple fibre, to be very brilliant and pliable, and to take up dyestuffs readily. The process is applicable to separate

fibres or to yarn, and is particularly suitable for silk as it is said to render the latter more brilliant than in its natural state.—S. H. H.

VII.—ACIDS, ALKALIS, SALTS, AND NON-METALLIC ELEMENTS.

Sulphuric acid lead chamber construction. F. J. Falding. Eng. and Min. J., 1909, 88, 441–444.

IN the author's opinion previous attempts which have been made to reduce the chamber space in the manufacture of sulphuric acid have been only partially successful, on account of the suction exerted on the gases owing to the "flue" shape of the chambers, tending to draw the gases forward before sufficient time has elapsed for quantitative reaction in the first portion of the system, where the conditions are best. It is claimed that a quantitative reaction can be obtained in one chamber by the author's process. The chamber is built of considerable height in proportion to its width, and the path of the gases is normally downwards, but owing to convection currents, the reacting gases tend to accumulate at the top of the chamber so long as the strongly exothermic reaction goes on, whilst the cooler non-reacting gases travel downwards, probably near the sides of the chamber. With a chamber constructed in correct proportions, it is claimed that the exit gases are free from sulphur dioxide, and only need cooling and drying before passing direct to the Gay-Lussac tower. Besides the saving in ground space effected by such chambers, much less lead is required; for a chamber or chambers of approximately 175,000 cb. ft. capacity, 66·5 short tons of lead are required for the author's system, 110 tons for Meyer's tangential chambers, and 112 tons for horizontal chambers. With a plant erected at Pittsburg, and for which the burners had to be forced, as their normal capacity was insufficient, the following results are said to have been obtained with a chamber of 175,000 cb. ft. capacity:—

	I.	II.
Sulphur burnt in 24 hours.....	25,600 lb.	23,200 lb.
Yield of acid at 60° F. in 24 hours	48 short tons	43·5 short tons
Sulphur dioxide in burner gases.....	7·0 per cent.	8·1 per cent.
Nitrogen dioxide in nitrous vitriol.....	2·2 per cent.	2·19 per cent.
Sodium nitrate (95 per cent.) used	720 lb.	720 lb.
Diff. of temp. at top and bottom of chamber.....	7° F.	8·3° F.
Temp. of gas entering Gay-Lussac tower.....	114° F.	115° F.

—A. S.

Glover tower; Acid-forming capacity of the —, and the power required in sulphuric acid manufacture. T. Meyer. Z. angew. Chem., 1909, 22, 1841–1844.

RASCHIG has lately suggested (this J., 1909, 706) a method of arriving at the acid-production of the Glover tower, and as a result of his investigations has made suggestions for the improvement of the chamber process. The author points out that it has always been possible to determine approximately the yield in the Glover tower, either by determining the sulphur dioxide and trioxide

in the gases entering the tower and leaving it, or by measuring the total yield of acid and the yield of each individual chamber over a given interval of time. The latter method, of course, includes in the make of the Glover tower, any acid which entered it as trioxide. Measurements made in this way, by the author, of two very different installations gave respectively 10.8 and 7.3 per cent. of the total make as the Glover tower's share, whilst the volume of the tower was in the first case 3.0 and in the other 3.8 per cent. of the volume of the chambers. Whilst these figures show a rather less acid-making capacity than Quincke found when using Raschig's method, they are still sufficient to suggest the desirability of assimilating further the conditions in the chambers to those in the Glover tower. The most important of these conditions is the removal by the sprinkling acid of the superfluous heat of reaction, and thus the maintenance in the tower of the most favourable temperature. The author has done something by his system of cooling tubes (this J., 1900, 823) to approach this condition in the chambers; but the ideal way of achieving it would be to use the acid formed in each chamber, starting next the Gay-Lussac tower, as a spray in the chamber in front of it. The practical difficulty in the way of this is the enormous cost of pumping the acid. He quotes the following figures, showing the cost for power in an existing system of chambers:—

Purpose of power.	Kilo-watt hours.	Per cent. of total.	Per 100 kilns of acid of 50° Baumé.		
			Cost, shillings.	Kilo-watt hours.	Cost, pence.
Lifting pyrites and residues	38	0.7	2.61	0.01	0.008
Working mechanical burner	478	8.9	32.80	0.10	0.082
Driving "Frithjof" fan...	434	8.1	29.80	0.09	0.074
Feeding water-spray	123	2.3	8.44	0.03	0.025
Cooling-water distribution	484	9.0	33.20	0.10	0.082
Air-compression for lifting and transporting acid ..	3819	71.0	262.08	0.81	0.667
	5376	100.0	368.93	1.14	0.938

An examination of the work actually done in raising the acid shows that there is an enormous waste of power here, and it is possible that improvements in efficiency may considerably reduce the very high percentage of the total power-cost now demanded by the handling of the acid; but it is clear that either in the method of working above suggested, or in the method suggested by Raschig, where from fourteen to twenty-one times the whole production of acid has to be lifted, the increased cost will be very great, and will need to balance it very greatly increased yield or very great economies in other directions. In the direction indicated, however, the improvements of the future are to be looked for.—J. T. D.

Potassium iodide; The presence of iodate in commercial —. A fallacy. L. W. Andrews. J. Amer. Chem. Soc., 1909, 31, 1035—1039.

THE general belief that commercial potassium iodide frequently contains iodate is erroneous and is not supported by the results of the author's examination of numerous samples of this substance. In no case was the presence of iodate detected. The production of a blue colour when a solution of an iodide is mixed with starch paste and acidified with hydrochloric acid is by no means a definite proof that iodate is present. Most samples of iodide contain minute traces of iron and cuprous iodide which, in the presence of atmospheric oxygen, lead to the liberation of free iodine and the production of the blue coloration. The test should be carried out as follows:—About 50 c.c. of a 10 per cent. solution of the iodide to be tested, are placed in a flask provided with a delivery tube, the outer end of which dips beneath the surface of a solution containing 1 gm. of potassium hydrogen tartrate and a little starch paste. The iodide solution is boiled and the steam allowed to pass through the tartrate

solution until all air has been expelled from both solutions. The flame is now removed from beneath the flask, and a tap or pinch-cock on the delivery tube is closed; when the iodide solution has cooled somewhat, the pinch-cock is again opened, and a portion of the still boiling tartrate solution is allowed to run into the flask. A blue coloration indicates the presence of iodate, iron oxide and cuprous iodide not yielding a reaction under these conditions. The test will detect the presence of 20 parts of iodate per million parts of iodide.—W. P. S.

Cuprous iodide; Solubility of —. M. Kohn. Z. anorg. Chem., 1909, 63, 337—339.

CUPROUS iodide is stated in text-books to be insoluble in a cold solution of potassium bromide. This is incorrect. Potassium bromide solution of 2*N* strength dissolves at 19.5° C. 1.47 grms. per litre, at 24° C. 1.56 grms. per litre. The corresponding figures for 3*N*-solution are 3.41 and 3.59, whilst 4*N*-solution at 22° C. dissolves 7.04 grms. per litre. These solutions slowly change, becoming greenish, yellow, and ultimately brown, whilst free iodine can be detected in the solutions.—J. T. D.

PATENTS.

Sulphurous acid; Recovery of — from solutions. Comp. Ind. des Alcools de l'Ardèche, Paris. Eng. Pat. 9145, April 17, 1909. Under Int. Conv., June 18, 1908.

FOR the rapid recovery of sulphurous acid from solutions containing it, such as those obtained by absorbing the gases given off during the roasting of sulphur or pyrites, these solutions are submitted to a violent mechanical action, for instance, by projection, in the form of a jet, against the vertical wall of a case, provided at its lower part with an opening for the escape of the separated water, and at the upper part with an orifice, through which the liberated sulphur dioxide gas is collected. The operation is repeated until all the acid is recovered. By slightly heating the solution beforehand, the liberation of the sulphur dioxide may be facilitated.—F. SOBX.

Sulphur dioxide; Process of purifying gases containing —. H. Hegeler, Danville, and N. L. Heinz, La Salle, Ill. U.S. Pat. 931,868, Aug. 24, 1909.

THE process consists in mixing hot sulphurous gases from a burner with sufficient cooled burner gases (of about equal sulphur dioxide content) to reduce the temperature below the boiling point of water, subjecting the mixture to the action of water trickling through a filled purifying tower, and drying and filtering the gases.—F. SOBX.

Sulphitometer, or tube for measuring [liquid] sulphur dioxide. P. V. Pacottet. Third Addition, dated Jan. 25, 1909, to Fr. Pat. 365,224, April 13, 1906 (this J., 1906, 928; 1907, 48, 255).

FOR the simplification of the apparatus, the cock controlling the entry of the liquid sulphur dioxide is omitted. Also, since ebouite is attacked by sulphur dioxide, its use is abandoned, and a hard wood impregnated with paraffin takes its place; boxwood, dogwood, quebracho, and algarroba are instanced as being suitable.—F. SOBX.

Sulphur trioxide, or a mixture of sulphur dioxide and oxygen, and anhydrous bases; Direct manufacture of — from metallic sulphates. M. Prud'homme. Fr. Pat. 400,030, May 16, 1908.

NATURAL or artificial sulphates are heated in an electric furnace, with the formation of anhydrous bases, and either sulphur trioxide or a mixture of sulphur dioxide and oxygen, which may be used for sulphuric acid manufacture by the contact process or otherwise. If silica, alumina, or ferric oxide be added to the sulphates, the decomposition of the latter is more complete.—J. R.

Nitric acid; Manufacture of —. Chem. Werke vorm. H. Byk. Fr. Pat. 400,305, Feb. 27, 1909. Under Int. Conv., Sept. 7, 1908.

CALCIUM nitrate, in the solid form or dissolved in the least possible quantity of nitric acid, is treated with sulphuric acid, and the calcium sulphate, which is deposited,

is filtered off and washed with dilute nitric acid, the washings being kept separate and used for dissolving the calcium nitrate in subsequent operations. The concentrations of the sulphuric and nitric acids used are so regulated as finally to yield a product containing as nearly as possible 59 per cent. of nitric acid.—O. R.

Sodium bicarbonate: Manufacture of —, D. Peniakoff. Fr. Pat. 400,241, Feb. 24, 1909. Under Int. Conv., Dec. 28, 1908.

CARBON dioxide is passed into a strong solution of sodium carbonate in the presence of a small quantity of ammonia or ammonium carbonate. The latter acts catalytically, combining with the carbon dioxide to form ammonium bicarbonate, which precipitates sodium bicarbonate and regenerates ammonium carbonate. The latter thus serves as carbon dioxide carrier and greatly accelerates the formation of sodium bicarbonate.—O. R.

Potassium-magnesium carbonate: Process for the decomposition of — for the recovery of potassium carbonate. Salzbergwerke Neu-Stassfurt. Ger. Pat. 211,798, Sept. 13, 1908.

THE solution containing the potassium-magnesium carbonate is treated at atmospheric pressure, or under increased pressure, with the calculated quantity of potassium hydroxide solution to produce normal potassium carbonate and hydrated magnesium carbonate:

—A. S.

Lime: Apparatus for hydrating —, C. C. Kritzer, Chicago, Ill. U.S. Pat. 932,789, Aug. 31, 1909.

SEVERAL closed hydrating cylinders are so arranged, that the lime is made to travel through them successively, in opposite directions in alternate cylinders, by means of a stirring device. Water is introduced near the end where the lime enters the uppermost cylinder, and means are provided for condensing the steam developed by the slaking, so as to produce a partial vacuum and maintain a draught of air towards the vapour outlet, in a direction opposite to that of the moving lime.—F. SOBY.

[Ammonium nitrate] *Crystals: Apparatus for the manufacture of* —, R. Knowles and P. Malone, Widnes. Eng. Pat. 19,960, Sept. 23, 1908.

THE apparatus consists of a number of jacketed glass tubes, A_1, A_2, A_3 , etc., arranged alternately with separating vessels, B_1, B_2, B_3 , etc. The liquid to be evaporated is fed into the jacketed feed-tank, I, and flows from this vessel through the first jacketed tube, A_1 , and thence into the first separator, B_1 , and so on through the series, being finally discharged in a concentrated state from the pipe, L. In order to economise steam, only a few of the jacketed tubes near the discharge end are supplied with steam from an external source. The steam enters through the pipe, K, into the jacket of the last tube, A_{10} , and passes thence through the jackets as indicated by the arrows. The condensed water is discharged through the pipes, J, provided with steam traps at their lower ends. The steam given off in the glass tubes and separated in the vessels, B_2 , to B_{10} , is conveyed by the pipes, F', into the main, F, by which it is conducted into the jacket

of the vessel, A_6 . Any steam not condensed in this vessel passes on to the jacket of the vessel, A_5 , along with the steam separated in the vessel, B_5 , and so on to the vessel, A_1 , from which any uncondensed steam passes into the jacket of the vessel, I.—W. H. C.

"Sodium sulphite" and ammonium chloride: Preparation of —, Dr. Friedrich und Co., Gloeska, Germany. Eng. Pat. 11,123, May 11, 1909. Under Int. Conv., June 20, 1908.

120 parts of common salt, suspended in 180 parts of water are treated first with a little sulphur dioxide, and then with a mixture of sulphur dioxide and gaseous ammonia in approximately equivalent proportions, the liquid being kept slightly acid up to nearly the end of the reaction, so as to prevent loss of ammonia. Finally the supply of gases is regulated so that the liquid becomes neutral, the proportion of sulphur dioxide being then about 9 to 19 parts by weight to 100 volumes of the neutral liquor. The heat of the reaction causes the deposition of anhydrous "sodium sulphite," which is filtered off, and the mother liquor is cooled to $35-40^\circ\text{C}$. for the separation of the ammonium chloride.—O. R.

Magnesium salts and ammonia: Process of making —, H. B. Hunter, Norfolk, Va. U.S. Pat. 932,130, Aug. 24, 1909.

MAGNESIUM oxide and an ammonium salt are mixed with water, and the temperature gradually raised; ammonia gas is evolved during the first stages of the operation and a mixture of steam and ammonia during the later stages, the latter being condensed to ammonia solution; the magnesium salt remaining in solution is recovered by crystallisation.—F. SOBY.

Magnesium salts from dolomite: Process of extracting —, with the simultaneous production of calcium carbonate. Rheinisch-Westfälische Kalkwerke and E. Fuchs. Fr. Pat. 398,826, Jan. 26, 1909.

CALCINED dolomite is heated with a solution of ammonium chloride, in quantity about equivalent to the lime present, and the magnesia, which under these conditions remains inert, is separated by filtration from the calcium chloride formed. The liberated ammonia is absorbed by cooled calcium chloride solution, and this, at the same time or subsequently, is treated with carbon dioxide, in order that calcium carbonate may be precipitated and ammonium chloride reformed.—F. SOBY.

Boric acid glass: Manufacture of soluble —, W. Ackermann. Fr. Pat. 400,132, Mar. 3, 1909.

A PRODUCT analogous to water-glass (alkali silicate) is obtained by heating a mixture of 3 to 4 mols. of boric anhydride, 1 mol. of anhydrous caustic alkali, and the equivalent quantity of water. The product, which is a viscous liquid, is claimed to be particularly suitable as a flux or for soldering.—O. R.

Hydrosulphites: Manufacture of anhydrous —, Badische Anilin und Soda Fabrik. Fr. Pat. 400,174, Feb. 6, 1909. Under Int. Conv., Dec. 4, 16, and 18, 1908.

HYDRATED solid hydrosulphites are heated in a vacuum desiccator at 100°C . until all the water, free and combined, has been driven off. The resulting anhydrous product is

perfectly stable in air, and may be mixed with: (1), 5 to 10 per cent. of its weight of calcined soda, caustic soda, quicklime, or the like; (2), alcohol or other inert organic liquid and a small quantity of caustic soda or ammonia, to form a paste; (3), molasses or glycerin; (4), an alcoholic solution of caustic soda, or of some inert salt, the mixture being subsequently well stirred for half an hour, and the alcohol finally distilled off.—O. R.

Brine; Process for the purification of natural —. E. Fontenilles et Cie. Fr. Pat. 400,657, June 16, 1908.

THE patent relates to the removal of calcium and magnesium salts before the water is concentrated for the production of sodium chloride. The water is heated to boiling and a quantity of sodium carbonate, or bicarbonate, sufficient to convert the calcium and magnesium sulphates into the corresponding carbonates, is added. The water is well stirred after the addition and the boiling is continued for a short time. The precipitated carbonates are then removed by filtration, and the filtered water is evaporated until the sodium chloride crystallises; the salt crystals contain but a very small amount of sodium sulphate. —W. P. S.

Organic copper salts, formates, acetates, etc.; Process of manufacture of — by means of cuprosocupric oxychloride obtained by the electrolytic process of "La Cuprosa française." A. Buisine and J. A. Cousin. Fr. Pat. 400,678, Mar. 12, 1909.

THE patent is for the manufacture of organic copper salts by the action of the corresponding acids, in hot aqueous solution, on the cuprosocupric oxychloride or copper oxychloride prepared by electrolysis of a solution of alkali chloride, using a copper anode.—F. SODX.

Thiosulphate; Process for the separation of — from solutions containing free alkali. J. Meschorer. Ger. Pat. 211,882, July 26, 1908.

THE solutions are treated with a quantity of fat, fatty acids, or resins, equivalent to their alkali content, and the resulting soap separated from the thiosulphate solution. —A. S.

Sodium nitrite; Process for the manufacture of —. J. Dittrich. Ger. Pat. 212,203, Jan. 14, 1908.

QUICKLIME is slaked with a concentrated solution of sodium nitrate, the pasty mass is well mixed with sawdust, and the mixture fused. After cooling, the product is treated with water, the sodium nitrite solution evaporated to a concentration of 45° B., filtered, and the nitrite recovered by crystallisation.—A. S.

Iron carbonyls; Producing —. L. Mond, London. Eng. Pat. 17,608, Aug. 21, 1908.

IRON carbonyls are produced by subjecting finely-divided iron to the action of carbon monoxide, under considerable pressure and at an elevated temperature. The temperature and pressure to be preferred, depend on the quality and manner of preparation of the iron. A convenient mode of procedure is as follows:—Finely-divided ferrous oxide is introduced into a suitable apparatus, such as a steel tube lined with copper, which is heated to 250°–300° C.; hydrogen is passed through, until reduction is complete, and then the apparatus is allowed to cool to about 150°–170° C., and a current of carbon monoxide is passed slowly through, at a pressure of 100–120 atmos.; the iron carbonyls are condensed by cooling the gas, issuing through the exit valve, to the ordinary temperature or to 0° C. By raising the pressure to 250 atmos., and the temperature to 200° C., a better yield is obtained. —F. SODX.

Non-metallic amorphous bodies; Process of deflocculating —. E. G. Acheson, Stamford, Ontario. U.S. Pat. 931,832, Aug. 24, 1909.

THE process is for disintegrating and deflocculating amorphous bodies by mixing them with a solution or extract

of cow-dung or other analogous material, and then grinding the mass and separating the deflocculated particles.

—F. SODX.

Oxygen from air; Apparatus for separating —. J. E. Johnson, jun., Long Dale, Va. U.S. Pat. 933,462, Sept. 7, 1909.

THE centrifugal separator used is provided internally with several series of coiled tubes, the inner coils communicating with the separator. A central inlet tube connects a source of cooled compressed air with the outermost series of coiled tubes. The separator is rotated by a turbine, driven by vaporisation of the separated nitrogen. Between the turbine and the centrifugal separator are a heat-exchanger and a sleeved connection. Means are provided for separating the incoming from the outflowing fluids, and for separating the liquid oxygen from the liberated nitrogen.—W. C. H.

Salt; Manufacture of —. B. F. McTear, Lea Green. U.S. Pat. 933,572, Sept. 7, 1909.

SEE Eng. Pat. 22,327 of 1906; this J., 1907, 1279.—T. F. B.

Sulphur dioxide; Process for recovering — dissolved in water or similar liquid. Cie. Indus. des Alcools de l'Ardèche. Fr. Pat. 400,735, June 18, 1908.

SEE Eng. Pat. 9145 of 1909; preceding.—T. F. B.

Alkali thiosulphates; Process of making —. Destrée et Cie. Fr. Pat. 401,099, March 22, 1909. Under Int. Conv., May 8, 1908.

SEE Ger. Pat. 208,633 of 1908; this J., 1909, 473.—T. F. B.

Silicon nitride; Process of making —. A. Sinding-Larsen and O. J. Storm. Fr. Pat. 401,256, March 26, 1909. Under Int. Conv., March 27, 1908.

SEE U.S. Pat. 928,476 of 1909; this J., 1909, 942.—T. F. B.

VIII.—GLASS, POTTERY, AND ENAMELS.

Crystallised silicates and their glasses; Relation between the refractive index and the density of some —. E. S. Larsen. Amer. J. Sci., 1909, 28, 263–274.

A STUDY of some silicate glasses and corresponding minerals in the soda-lime felspar series and in the 3-component system, $\text{CaO}-\text{MgO}-\text{SiO}_2$, shows that neither refractive indices nor specific volumes are strictly additive functions. The specific refractivity, calculated from the formula of Gladstone and Dale, $\frac{n-1}{d} = K$, in which n is the refractive index and d is the density, or from that of Lorenz and Lorentz, $\frac{n^2-1}{d(n^2+2)} = K$, is additive for the glasses and nearly so for the felspars, but when crystals are compared with glasses of the same composition, or with other crystals, the values of the specific refractivity may differ by as much as 11 per cent., being usually higher for the glasses. The above formulae appear to hold one as well as the other.—F. SODX.

PATENTS.

Quartz glass; Process for melting and working —. H. Mehner, Friedenau, Germany. U.S. Pat. 931,945, Aug. 24, 1909.

QUARTZ is heated under pressure, until very liquid, by means of one or more electric arcs in a furnace provided with reflecting surfaces, which concentrate the heat-rays on the quartz. The pressure is then reduced to that of the atmosphere, the molten material is allowed to cool somewhat, and the viscous material is worked into shape, a draught being maintained from top to bottom through the furnace.—A. G. L.

Kiln [for burning china, terra cotta, earthenware, and the like]; Continuous —. W. H. Smith, Swinton, Lanes. Eng. Pat. 19,525, Sept. 17, 1908.

IN a muffle kiln heated by gaseous fuel, fire-holes are situated near the bottom of one side of the kiln, and flues,

of the same size as, and exactly opposite to, the gas inlets, are situated in the opposite wall of the kiln, and convey the heated gases through the hollow wall and arch, back to the firehole side, and thence by way of horizontal flues to the chimney. The material to be burnt is placed on a series of trucks, which run on rails laid in the bottom of the kiln. Each truck contains a series of transverse passages under a platform, on which the goods to be fired are placed, these passages corresponding exactly in dimensions and in position with the gas inlets and flues of the kiln, when the truck has assumed its correct position in the latter, and thus serving as flues for the circulation of the heated gases. The heat is greatest in the centre of the kiln and decreases in intensity at each end. In the continuous operation of the kiln, the raw material is placed on trucks, which are moved into the kiln; each truck remains for the required time near the entrance; it is then moved along its own length and again remains in position for a specified time, and so on until it reaches the centre of the kiln, where the firing is completed, after which it proceeds in a similar manner through zones of decreasing intensity, until it emerges sufficiently cooled.—O. R.

Fusible bodies [Seger cones] from silicate mixtures for temperature determinations. Chem. Lab. für Tonind. und Tonind.-Zeit. H. Seger and E. Cramer, Ges.m.b.H. Ger. Pat. 212,496, Sept. 30, 1908.

The irregular melting of fusible bodies, such as Seger cones, used for temperature determinations, is stated to be due to the lead oxide and calcium carbonate used as fluxes in their preparation. According to the present patent, a mixture of potassium oxide and magnesium oxide is used in place of lead oxide and calcium carbonate.—A. S.

Enamelling metal ware; Substitute for tin oxide used for —. R. Weimer, Sheboygan, Wis. U.S. Pat. 932,839, Aug. 31, 1909.

THE substitute for tin oxide consists of a mixture of 70 parts of antimony oxide, 28 of sodium hydroxide, 22 of Chili saltpetre (sodium nitrate), 10 of kaolin, and 10 of barytes (barium sulphate). The mixture is "boiled," roasted, and ground.—A. G. L.

Glass or other furnaces; Means for discharging molten material from —. L. Rembaux, Maustier sur Sambre, Belgium. Eng. Pat. 25,901, Dec. 1, 1908.

SEE FR. Pat. 397,548 of 1908; this J., 1909, 795.—T. F. B.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

Asbestos deposit in the Urals. Chem. Ind., 1909, 32, 530—531. [T.R.]

IMPORTANT deposits of asbestos are said to have been discovered in the Orenburg Government in the Urals, chiefly at Peyau-Tschin and Ak-Zigit. The deposit at the latter place extends over about 21 sq. miles. The asbestos is found in large veins of serpentine embedded between a silicious schist and porphyry; outcrops of the serpentine occur in places. The veins have in general a length of from 350 to 1400 feet, but occasionally extend to as much as 2100 feet. The asbestos appears an olive-green colour in the rock, but individual fibres are pure white and very soft and woolly; the quality of the asbestos does not diminish with the depth of the deposit. The land on which the deposits occur belongs to the Baschkirs, but has been leased to the Süd-Uralische Asbest-Ges. for 40 years.—A. S.

Portland cement; Free lime in —. A mill study. A. G. Smith. J. Ind. and Eng. Chem., 1909, 1, 668—670.

SAMPLES of finished cement were taken from the four tubemills of a Portland cement factory at intervals of 1 hour during every day (24 hours) of the period June 3 to June 16, 1909. The samples were tested for free lime by White's microscopic test, depending upon the formation of crystals of calcium phenolate (see this J., 1909, 23), and were also

examined as to fineness, setting time, and soundness. The results, given in tabular form, show that the soundness of the cement, as predicted from the observations in the microscopic test, in most cases corresponded well with the results obtained by the boiling test, and the author considers the microscopic test of considerable value as an aid in controlling the manufacture.—A. S.

Magnesium oxide; Influence of the temperature of burning on the rate of hydration of —. E. D. Campbell. J. Ind. and Eng. Chem., 1909, 1, 665—668.

THE magnesite used in the experiments gave the following results on analysis: silica, 1.24; lime, 1.94; alumina and ferric oxide, 1.32; magnesia, 44.40; and loss on ignition, 51.06 per cent. For temperatures up to 1000° C. a Heraeus platinum resistance furnace was used, 16—18 grms. of the finely-ground magnesite in a magnesia crucible were heated to different temperatures, measured by means of a platinum-rhodium thermo-couple embedded in the magnesite, another couple being placed in the annular space between the crucible and the wall of the furnace. The temperature was raised gradually and maintained at the desired point for 1 hour. For temperatures above 1000° C., a specially designed platinum resistance furnace was used, and the magnesite was first burned at a low red heat to completely destroy carbonaceous matter, which would otherwise have injuriously affected the thermo-couple. After burning, the samples were ground to pass a 100-mesh sieve, and their rates of hydration determined. It was found that at 500° C. in one hour, the magnesite was not completely dissociated. At 600° C. magnesium carbonate was completely dissociated in 1 hour, but calcium carbonate was not. Magnesium oxide burnt at 600°, 700°, or 800° C. was practically completely hydrated by immersion in water for 3 days. Between 800 and 900° C. the dissociation of the calcium carbonate was complete. At this temperature, combination took place between acidic and basic oxides, with formation of silicates or aluminates, which on hydration, combined with more water than was necessary for the complete hydration of the basic oxides alone. Magnesium oxide burnt at a temperature of 1000—1100° C. showed a much lower rate of hydration, and this change became more marked with increase of temperature of burning; a sample burnt at 1450° C., or nearly the temperature required for burning Portland cement, combined with only 6.14 per cent. of the water required for complete hydration, after 18 months' immersion in water. The relation thus shown between the rate of hydration and temperature of burning of magnesia explains in some measure the conflicting views as to the injurious effect of magnesia in Portland cement. (See also this J., 1906, 1097.)—A. S.

Cementitious material; Determination of — in mortar and concrete. Framm. Tonind.-Zeit., 1909, 33, 1193—1196.

THE determination of the amount of cement present in concrete falls under three heads, according as samples of the following are available for analysis: (1), The concrete only; (2), the concrete, and either the cement or the filling material used in its manufacture; (3), the concrete and both the cement and the filling material. The determination can in any case only give approximate results. The concrete is dissolved in hydrochloric acid, and the insoluble residue is washed with hot water and extracted with sodium carbonate solution of 5 per cent. strength, which dissolves the soluble silica formed by the decomposition of the cement. The insoluble residue is ignited and weighed, and a separate test for loss on ignition is also made with another sample of the original concrete. The ratio of the weight of the insoluble residue to the weight of matter soluble in acid, after making the requisite allowance for the loss on ignition of the latter, indicates the ratio of filling material to cement in the original concrete, if its ingredients were pure quartz-sand and Portland cement only. If the soluble matter on analysis is found to contain the ordinary ingredients of Portland cement in the same proportions as in normal cement, it may safely be assumed that the

concrete consisted of pure quartz-sand and of pure cement, and that the ratio arrived at in the above estimation is a fairly reliable valuation of the concrete analysed. On the other hand, if the relative amounts of silica, iron and aluminium oxides, lime, magnesia, and sulphuric acid, found in solution, are appreciably different from the proportions corresponding to the composition of Portland cement, the filling material must have contained matter soluble in hydrochloric acid, and the analysis of the concrete only, is useless for estimating its cement content. In the second case, when a sample of the cement used is available, if the composition of the latter is found on analysis to correspond with that of the portion of the concrete which is soluble in acid, the ratio of insoluble residue to soluble matter in the concrete may be taken to represent the ratio of filling material to cement present. When a specimen of the filling material used is available, analyses of average samples are made to determine the amounts of insoluble residue, and of soluble silica and matter soluble in acid, which are present in the filling material. On then analysing the concrete as in case (1), from the amount of insoluble residue obtained, the soluble matter due to the filling material is calculated, and subtracted from the total amount of soluble matter found. The remainder gives the amount of soluble matter, which is taken to be the cement originally present in the concrete, due allowance being made for the losses on ignition, which are determined separately in each case. In the third case, where samples of the concrete and of each of the constituents can be analysed, the composition of the cement should correspond with the figures obtained by difference in the last-mentioned case, and when this is so, the results obtained represent the constitution of the concrete fairly accurately.—O. R.

PATENTS.

Building material; Manufacture of — capable of serving as a substitute for wood or the like. K. Winkler, Zürich, Switzerland. Eng. Pat. 25,637, Nov. 27, 1908. Under Int. Conv., Dec. 6, 1907.

FIBROUS material, such as moss-peat or the like, is comminuted and then kneaded with a 10 per cent. solution of a drying substance, such as calcium sulphide, with, if desired, 2 to 10 per cent. of lead sulphide, or the like, and then strongly heated. It is next mixed in a heated ball mill with a binding material, such as sulphur, resin or asphalt, either alone or with a filling substance such as silica, dolomite, kaolin, basic copper and lead carbonates, etc. After being minutely divided during mixing, the heated material is moulded into suitable forms under a pressure of about 300 atmospheres. If the material is required to withstand the action of water, in addition to the binding material, up to 15 per cent. of resin distillate or the like, with or without drying oils, is added. The strength of the material may also be increased by the use of metallic skeletons.—F. R.

Wood; Art of colouring or transforming —. W. A. Hall, New York. Assignor to American Mahogany Co. U.S. Pats. 933,435 and 933,436, Sept. 7, 1909; and W. A. Hall, U.S. Pat. 933,437, Sept. 7, 1909.

(1). Wood is impregnated throughout with a colouring solution, the constituents of which have varying powers of penetration and capillarity, so that a comparatively large amount of colouring matter is deposited in the outer portions of the wood, and a relatively lesser amount in the inner portions. (2). A colouring solution is forced into and throughout the wood by heavy pressure, after the air has been removed from the pores by placing the wood in a vessel from which the air is exhausted. The surplus colouring solution is drawn from the vessel, and the impregnated wood is subjected to the action of steam in order to diffuse the colour in the wood. It is claimed that the colouring matter is properly diffused throughout the wood and the grain cells are fully developed, so that in the final product the harder heart portions of the wood are of a colour as dark as or darker than the sap portions. (3). Wood is boiled under pressure at temperatures above 220° F. in an alkaline colouring

solution containing saccharine matter, by which process the heart portions of the wood are coloured to darker shades than the sap portions.—W. C. H.

Granulators for molten slag or other substances. W. R. Warren, New York. Eng. Pat. 1236, Jan. 18, 1909.

A GRANULATING house is so arranged that a section of the periphery of a large horizontal cooling table, rotating in the open air passes through it. The molten slag, which is granulated by falling on to a revolving drum, is conveyed away by the table, and becomes sufficiently cool by its passage through the open air to permit of its removal, without agglomeration, by means of a scraper situated where the table re-enters the granulating house.—F. R.

Bricks from clay; Process for moulding — in the dry state. H. Schulte-Steinberg. Fr. Pat. 400,558, Mar. 9, 1909. Under Int. Conv., Aug. 22, 1908.

CLAY is mixed and dried by passage down an inclined rotating cylinder in which it meets hot flue-gases. The dried clay then passes through a chamber, traversed by the flue-gases on their way to the kiln, to the grinding rolls; the ground material is delivered by an elevator to the top of a shoot, from which it falls on to an inclined sieve to which a reciprocating motion is imparted. Any coarse material is returned to the rolls; the fine material falls into a hopper, from which it is automatically fed to a press, in which it is moulded dry and whilst still warm. The moulded bricks are burnt immediately after leaving the press.—A. G. L.

Calcareous stone; Process of colouring and hardening — so as to imitate natural marble and onyx. P. Charbonnier. Fr. Pat. 400,638, Mar. 10, 1909.

To imitate veined and coloured onyx, calcareous stone is first heated to 60°–80° C., and then plunged into cold 10 per cent. hydrochloric or sulphuric acid. The stone is then removed from the acid, again heated, and plunged into a solution of an acid colour in dilute alcohol heated to the same temperature, the veins or cracks produced by the acid treatment absorbing more colour than the rest of the stone. These veins may also be coloured differently by covering the stone around the veins with powdered colours, and then treating with alcohol, so as to cause the colours to permeate the veins. The stone is next hardened by immersion in a solution containing copper sulphate and hydrofluosilicic acid, and is finally polished. To imitate coloured marble free from veins, the procedure is similar, but the acid treatment is omitted; different colours may be applied, one after the other, followed by treatment with cold alcohol. To obtain white "statuary" marble, the stone is simply boiled for 15 minutes in a 20 per cent. solution of sulphuric acid.—A. G. L.

Portland cement; Waterproof — and process of making same. C. McCormick, St. Louis, Mo., Assignor to Meramec Portland Cement and Material Co., Phoenix, Ariz. U.S. Pat. 931,884, Aug. 24, 1909.

CEMENT is rendered waterproof by mixing it in the dry state with a sulphate or sulphates and an alkaline base which will form a colloidal precipitate with the sulphate when the cement is treated with water. A filling material may also be added.—A. G. L.

Cementitious compound; Fixed-colour — and process of producing the same. A. C. Horn, New York. U.S. Pat. 932,280, Aug. 24, 1909.

A CEMENTITIOUS compound having a "fixed colour" is produced by mixing a caustic alkali and a fatty acid with an iron pigment, so as to produce fatty acid salts (stearates) of the alkali and of iron, then adding an additional iron pigment, and mixing with cementitious material. The fatty acid salt of iron and the additional iron pigment should have approximately the same colour, and the specific gravity of the mixture should be greater than that of water.—A. G. L.

Portland cement; Method of making — J. M. Carrère, Assignor to Blanc Stainless Cement Co., Allentown, Pa. U.S. Pat. 932,374, Aug. 24, 1909.

A MIXTURE of calcium oxide or carbonate, a silicious material, and zinc carbonate or other zinc salt, all free from iron, is burnt, and the resulting clinker is powdered. —A. G. L.

Cement; Process for manufacturing — M. Tremblour, Birmingham, Ala., Assignor to Putnam Development Co., New York. U.S. Pat. 932,917, Aug. 31, 1909.

DILUTE sulphuric acid is intimately mixed with molten blast-furnace slag, to which calcium oxide or hydroxide may first be added. —A. G. L.

ALLOY S

Fig. 2.

THE authors have investigated the causes of the "growth" (permanent increase in volume) of cast-irons such as are used in annealing ovens, furnace grates, etc. In a preliminary experiment it was found that bars of grey iron started growth at about 650° C., and reached their maximum after three hours at 730° C., and that alternate heating and cooling was necessary to the growth, seventeen hours' continuous heating having no greater effect than three hours. For the investigation, bars were accurately machined to 6 in. in length, and 1 in. diameter, being measured by calipers to 0.0001 of an inch. They were heated for four hours at 900° C. in an iron retort, enclosed in a clay muffle; the lid of the retort was well luted on, and carried an iron tube for the thermo-junction. Cooling taking place overnight, the measurements were made in the morning. The first series employed were commercial grey irons used for annealing ovens. After heating 99 times, the increase was 35 to 37 per cent. in volume, and 8 per cent. by weight. The second series (B to I) consisted of cast-irons varying from 4.03 to 0.15 per cent. of carbon, and about 2 per cent. of silicon, with small constant amounts of manganese, sulphur and phosphorus. Samples were cast in both sand and chill moulds, and were white irons giving, after heating for 50—90 times, a permanent shrinkage in volume and weight of not more than 1 per cent. This composition indicates the practical solution of the problem. The third series (J to M) varied from 4.6 to 3.0 per cent. of carbon, 0.5 to 0.79 per cent. of silicon, about 1 per cent. of manganese and low sulphur and phosphorus. J was a grey iron, K and L were white irons with a little graphite, and M a white iron. The first three grew steadily for sixty-eight heats, reaching 11, 7 and 6 per cent. increase respectively. M contracted during ten heats, and then increased in volume, finally reaching 6.2 per cent. after 58 heats. A set of short control pieces of M similarly heated showed that temper-carbon, previously absent, began to be formed at the tenth heat, and increased in quantity during the rest of the heats, showing that, as with graphite, temper-carbon is a factor in promoting growth—that is, increase in volume. The following table gives the fourth series, designed to determine the influence of silicon, with the results of the treatment. In the series N

to S, the alloys Q, R, S containing no combined carbon, the graphite content was nearly constant.

Alloy.	Combined carbon.	Graphite.	Silicon.	Percentage growth on heating.	Percentage increase in weight.	Percentage loss of carbon 25 heats.
N.....	0.64	3.34	1.07	15.40	0.65	3.84
O.....	0.68	3.30	1.79	23.46	1.89	39.7
P.....	0.30	3.49	2.06	32.85	3.62	31.4
Q.....	nil	3.76	4.20	43.9	9.59	26.3
R.....	nil	3.79	4.83	59.5	10.25	14.3
S.....	nil	3.38	6.14	63.0	13.20	nil
T.....	0.17	nil	0.65	-0.025	-0.04	—
U.....	0.18	nil	1.10	0.000	-0.03	—
V.....	0.19	nil	2.71	+ 0.394	-0.02	—

while the silicon content varied from 1.07 to 6.14 per cent. The "growths" are fairly proportional to the silicon content, the greatest being obtained with one of the alloys containing no combined carbon. The alloys, Q, R, and S, were all cracked, and greatly distorted (see Fig. 1). As these alloys were cut at haphazard from the casting, and P and S were near the gate, a duplicate set was cut from the top of a "riser." The rate of growth of these was much slower, although the final increase of volume was about the same. It appears therefore that the dissolved gases play a physical part in the growth; at the same time the increase in weight of the alloys shows that the external gases probably play a physical and a chemical part. This increase in weight can only be explained on the assumption that the ferrous silicide is oxidised by carbon dioxide into ferrous oxide and silica, which greatly overbalances the decrease in weight due to oxidation of carbon, which latter diminishes with increasing silicon content, and was nil at 6 per cent. It is also suggested that some part of the increase is due to oxidation of iron itself. Microscopic examination of control specimens of 3 per cent. carbon content, heated with the other bars and removed after from one to twenty-one heats, showed that the graphite was removed from its original position; the spaces so left showed oxidation, and numerous small holes were formed, the whole structure being revolutionised. The alloys, T, U, V, contained no graphite, and the results of fifteen heats are given in the table. These results show that carbon, in the form of either graphite or temper-carbon, is an important factor, in addition to the silicon-content. The authors now investigated the influence of gases. A bar of alloy S, heated *in vacuo*, gave 1.11 times its own volume of gases consisting of 87.5 per cent. of hydrogen, and 12.5 per cent. of nitrogen. It shrank in volume 0.04 per cent. The same alloy had grown 62 per cent. in volume, and 12.26 per cent. by weight, when heated in the muffle. A similar bar was now heated to 900° C. *in vacuo* till it ceased to evolve any gas; it was then heated in the muffle. After 21 heats it had grown 4.08 per cent.; after 30 heats, 9.7 per cent.; but then grew rapidly, reaching 67.7 per cent. at the fifty-third heat (see Fig. 2). It also had not cracked, and kept its cylindrical form perfectly. On now heating *in vacuo* it evolved gases, consisting of 33 per cent. of carbon dioxide, 14.54 per cent. of carbon monoxide, 42.50 per cent. of hydrogen and 9.96 per cent. of nitrogen. A similar experiment with alloy N showed an increase of 11 per cent. on heating *in vacuo*, which seems to show that the dissolved gases in a close-grained alloy (N) can cause growth because of their difficulty in escaping, as contrasted with (S), an open-grained alloy. The authors conclude that a white cast-iron of about 3 per cent. of carbon and other non-ferrous constituents as low as possible will not "grow;" an alloy of higher carbon content tends to deposit temper-carbon and will ultimately increase in volume, although not to a great extent. The main causes of "growth" are:—1. The disintegration of the material due to the oxidation of the ferrous silicide into ferrous oxide and silica by the furnace gases. 2. In the case of close-grained irons, to the evolution of dissolved gases.—A. H. C.

Iron-carbon alloys; Development of the equilibrium diagram of the —. F. Wüst. Metallurgie, 1909, 6, 512—531.

THE author traces the history of the development of the

iron-carbon diagram, and then communicates some results recently obtained in his own laboratory. For the eutectic

mixture (mixed crystals—cementite) which constitutes pure white cast-iron with 4.2 per cent. of carbon, the name "ledeburite" is proposed. A new diagram (see Fig.) is proposed, which differs from that of Goerens-Benedicks (1907) chiefly in that the point, E, which marks the maximum carbon content of the solid mixed crystals is shifted from 2.0 to 1.7 per cent. of carbon; in the convex shape of the line, AE (pure iron to E); and in the upper limit, LS, of the pearlite + ferrite field, which is made to slope downwards towards the left. The author believes that in molten iron practically all the carbon is present as carbide, and that two forms of graphite are produced on cooling, the first ("Garschaungraphit") from the carbide separating out from the still liquid melt, and the second ("Erstarrungsgraphit") from carbide present in the metal, either during or immediately after solidification. In addition, elementary carbon exists as hardening carbon, formed only after complete solidification has taken place. Graphite can be formed even if no foreign substances (silicon, manganese, etc.) are present. Foreign substances influence the formation of graphite in two ways: Directly, by entering into the constitution of the carbide and accelerating its rate of decomposition (e.g., silicon, nickel, aluminium), or retarding it (e.g., manganese, chromium, tungsten); and indirectly, by altering the solubility of cementite in liquid or solid iron, and consequently altering the quantity of carbide which separates out. The influence of foreign substances on the formation of hardening carbon is due to similar causes. Decom-

position of the carbide in the solidified metal is favoured by prolonging the time of cooling and takes place with absorption of heat. In titanium also, graphite may be present in two forms.—A. G. L.

Pearlite; A new structural form of —. C. Benedicks. *Metallurgie*, 1909, 6, 567–568.

The author describes the occurrence, in a grey pig-iron, of a form of pearlite, in which the well known layers of cementite are broken up into strings of beads, the longer axes of which are at right angles to the original direction of the laminae. With only casual observation these rows may be mistaken for lamellar pearlite, but are quite distinct at high magnifications (1500 diam.). The term, beaded-pearlite, is suggested for this modification, and it is shown to be a transition form between lamellar and granular pearlite. Three microphotographs illustrate its characteristics.—A. H. C.

Steels; Constitution of carbon-tungsten —. T. Swinden. *Iron and Steel Inst.*, Sept., 1909. [Advance proof.]

SAMPLES of three of the steels used in a previous work by the author on carbon-tungsten steels (this J., 1907, 694) were submitted to various heat-treatments and either quenched or air-cooled. The steels contained about 3 per cent. of tungsten and 0.57 per cent., 0.89 per cent., and 1.24 per cent. of carbon respectively. The quenched specimens showed that the constitution of the steels above the "lowering" temperature was preserved down to the lowered A_1 temperature, irrespective of the rate of cooling, while the specimens heated to above the "lowering" temperature, cooled slowly to below the lowered A_1 point, and then quenched, gave the ordinary constituents—ferrite, pearlite, and cementite—found in normal steels. Owing to their small size the air-cooled specimens were cool enough to handle two or three minutes after they had been withdrawn from the furnace, and those heated to 1250° C., *i.e.*, above the "lowering" temperature, all preserved a portion of the martensite, the amount being in proportion to the carbon content of the steel. On the other hand, when heated to 1000° C., *i.e.*, below the "lowering" temperature, and air-cooled, the steels showed no sign of hardening. The change at the lowered A_1 point was more sluggish than at the normal A_1 , and 3 per cent. of tungsten was thus sufficient to produce an air hardening effect. The author is of the opinion that the change that occurs at the "lowering" temperature is the solution of a tungsten compound, probably Fe_3W , and that this compound is reprecipitated at the lowered A_1 , iron carbide immediately separating also. Tests were also made of the resistivity of the heat-treated specimens, the increased resistivity of tungsten steels quenched from above the "lowering" temperature lending support to the author's theory.—O. F. H.

Copper-clad steel—a new metallurgical product. W. Tassin. *J. Ind. and Eng. Chem.*, 1909, 1, 670–673.

THE author states that by a recent process (see Eng. Pats. 8913 and 8913A of 1906; this J., 1907, 532, 696), it has been found possible to successfully weld copper to steel in such a manner that the product will stand the ordinary methods used for working metals. The two metals when welded, have, it is stated, practically the same rate of flow, *i.e.*, on rolling the copper-clad steel, the relative thicknesses of the two metals remain the same. The strength of the copper-clad steel is said to be, under certain conditions, equal to, if not greater than, that of steel. The compound metal resists corrosion just as copper does, except at the ends where both steel and copper are exposed, but even here, after a certain time, corrosion practically ceases. It is believed that after a certain amount of corrosion has taken place, a thin film of copper, mixed with some copper oxide, becomes deposited between the rust and the underlying steel, and that this film so long as it remains unbroken, prevents further corrosion.—A. S.

Iron ores; Arbitration analyses of —. Committee appointed by the "Verein deutscher Eisenhüttenleute." *Chem.-Zeit.*, 1909, 33, 959–960.

COMPARATIVE analyses of carefully sampled iron and manganese ores in 9 works and 6 consulting laboratories showed that large differences, amounting to several per cent. for lime and manganese, are occasionally found between the different analyses. In general, the results of the works laboratories were more concordant than those of the consulting laboratories, although the mean of both series was usually very similar. It is suggested that in many cases it would be best for buyer and seller to have their own analyses made after mutual agreement as to methods of analysis; results which diverge more from each other than 0.5 per cent. for iron, manganese, or silica, and 0.05 per cent. for phosphorus should be entirely disregarded.—A. G. L.

Gold precipitates and bullion; Smelting of — with oil fuel. A. Yates. *J. Chem. Met. and Min. Soc. S. Africa*, 1909, 9, 429–431.

Two Fabre du Faure tilting furnaces are employed at the Redjang Lebong gold and silver mine, Sumatra, for smelting the precipitates obtained in the usual zinc boxes in connection with the cyanide extraction plant. In April, 1908, they were adapted for the use of kerosene oil as fuel, whereas previously a mixture of coke and charcoal had been employed. The furnaces were filled in with firebricks, leaving a space of two inches around the sides and bottom of the retort. Half of an old retort, cut longitudinally, was fixed as a hood over the neck of the retort, resting on the brick in the flue at the back. Just below the retort, and centrally in the furnace, two pieces of 3-in. pipe were built in the brickwork, and in these the "Billow" atomisers, class "F M." of the National Supply Co., Chicago, were placed, their brass shells being protected by a cover of 2-in. piping screwed on them, and projecting 1 in. in front. A 20-gallon oil tank was placed 18 feet above the atomisers, and connected to them by flexible steel tubing. Air was delivered at 40 lb. pressure through a 2-inch main with $\frac{3}{4}$ -inch branches and $\frac{1}{2}$ -inch cocks. The air was heated by having 14 feet of the main coiled in the stack at the junction of the two furnace flues. A 2-inch mica sight hole was fitted in front for observing the behaviour of the atomisers. Each furnace dealt with 1200 lb. of precipitate per day. During May, 1908, one gallon of oil for every 12.47 lb. of roasted precipitate was used; the time occupied was 60 hours as against 140 hours when using coke and charcoal, that is, a smelter and four boys were working 6 days a month instead of 14 days as previously. The author gives the full log return for the months of March and May, that is, before and after the introduction of oil fuel.—A. H. C.

Gold; Adsorption of — by charcoal from aqueous solutions of its compounds. S. Brussow. *Z. Chem. Ind. Kolloide*, 1909, 5, 137–138.

POWDERED bone charcoal, wood charcoal, coke, and retort graphite were used with solutions of gold salts, usually the chloride. The limits of the adsorption were not determined; the gold solution was either shaken with, filtered through, or allowed to stand in contact with, the powdered adsorbent. 0.2 gm. of gold chloride in 100 c.c. of water was completely adsorbed on shaking a few times with 1 gm. of bone charcoal, dried at 110° C. On filtering a solution of gold chloride, containing 0.066 gm. of gold, in 2285 c.c. of water, through a layer of 1 gm. of powdered bone charcoal, the gold was completely adsorbed; gold was adsorbed in a similar manner from solutions of the bromide, iodide, and gold-potassium cyanide. It was also adsorbed in presence of the salts contained in sea-water. Similar results were obtained when the bone-charcoal was replaced by wood-charcoal. Gold adsorbed by charcoal was readily redissolved by treatment with *aqua regia*, chlorine-water, or bromine-water. Coke and retort graphite also adsorbed gold

from its solutions. The chlorine of gold chloride is stated to have remained "almost entirely" in solution in the liquid after adsorption of the gold in the above experiments, but the author states that he did not examine this question quantitatively.—E. F.

Gold-magnesium alloys. R. Vogel. Z. anorg. Chem., 1909, 63, 169—183.

THE author has prepared a large number of alloys of gold and magnesium, and gives a melting point curve on a scale of the percentage of magnesium atoms corresponding to the percentage composition by weight, which latter is also given in the diagram. Three maxima occur, corresponding to the compounds, AuMg, AuMg₂, and AuMg₃. While gold melts at 1064° C., these alloys melt at 1160° C., 796° C., and 830° C. respectively. It is to be noticed that the alloy, AuMg₂, melting at 796° C., is marked by only a very slight rise in the curve. Cooling curves of these alloys showed complete crystallisation at their melting points. The eutectic points occurred at 833° C., 782° C., 774° C., and 576° C. Up to 3 per cent. of magnesium the alloys are yellowish; above that they are of a fairly uniform grey colour. Between 5 and 20 per cent. they are brittle, with a glassy fracture; as the gold increases, the fractures become granular, and the hardness decreases in proportion to the gold present. At ordinary temperatures the alloys are permanent in the air, and only those containing free magnesium (26 to 100 per cent.) are affected superficially by moist air. Alloys containing between 20 and 26 per cent. of magnesium crumble to a brown mass on heating to 600° C., while those with little magnesium are unaffected by heating to a higher temperature. The alloys containing up to 11 per cent. of magnesium are attacked only by *aqua regia*, those with from 11 to 16 per cent. by concentrated nitric acid, and those with a higher magnesium content by dilute acids. In order to prepare the alloys, the magnesium was melted, and gold sheet added as necessary. The union was always accompanied by a very large evolution of heat, in some cases almost to explosiveness. The same characteristic occurs in the alloys of gold with zinc and cadmium, and indeed forms a series in accordance with the periodic system, the heat evolved increasing with falling atomic weight. The miscibility of the gold with magnesium in the solid state, with the formation of mixed crystals, is up to 3 per cent., and with zinc and cadmium up to 5 per cent. Twelve microphotographs illustrate the paper.—A. H. C.

Manganese, aluminium, and copper; Magnetic properties of alloys of —. A. D. Ross and R. C. Gray. Z. anorg. Chem., 1909, 63, 349—352.

COMMENTING on the paper of Heusler and Richarz (this J., 1909, 246), the authors point out that the hysteresis of these alloys varies greatly in samples that have been cooled at different rates after heating to a high temperature: slow cooling gives a material with strong hysteresis, whilst quenching produces a material almost destitute of hysteresis. The temperature from which the alloys are quenched, however, has great influence on the hysteresis: an alloy quenched from 500°, 610°, 660° C., had saturation values for I in the ratio of 4:2:3, whilst their losses from hysteresis were as 3:7:10. In the case of the second sample, cooling to —190° C. increased I by 65 per cent., while the hysteresis loss increased by only 5 per cent. These quenched alloys, free from hysteresis, are unfortunately of little use, for not only is their permeability low, but they are unstable. The effects, on Heusler's alloys, of quenching, and of the temperature of liquid air, are quite different from their effects on copper, manganese, manganese-bronze, and aluminium-bronzes with 5 per cent. and with a high percentage of aluminium, but are closely analogous to the effects on an aluminium bronze of practically the composition, Cu₃Al. The presence of the compound, Cu₃Al, is of great influence in determining the magnetic characters of aluminium-copper alloys, and it is highly probable, as Heusler and Richarz suggest, that the compound, Mn₃Al, may be of analogous importance.—J. T. D.

Aluminium; Use of — as electrical conductor. U. Del Buono. Atti Assoc. Elettrotecn. Ital., 1909, 13, 261—289.

THE author recommends the use of aluminium in place of copper as an electrical conductor in electric furnaces and for conveying high-tension currents, and especially for wires for current-transmission lines. For overhead wires the greatest economy effected by the use of aluminium is in the case of relatively short distances, with the supporting standards from 30—50 m. apart. For longer distances and with iron standards at longer intervals, more standards are required for aluminium than for copper wire, and thus the saving is somewhat less. Aluminium appears to be specially useful for conveying alternating currents to electric furnaces, the loss through eddy currents being 40 per cent. less than when copper is employed. (See also this J., 1897, 73; 1901, 133; 1904, 826).—A. S.

Tin-lead alloys. P. N. Degens. Z. anorg. Chem., 1909, 63, 207—224.

THE author has examined tin-lead alloys by the three methods, thermometric, dilatometric and micrographic. The melting-point curve shows a eutectic temperature of 181° C., which is present in alloys from 0.2 to 88 atoms of lead per cent. The dilatometer confirms the presence of this eutectic. A series of fourteen microphotographs forming a series of varying composition shows the structure of the eutectic at 23.6 atomic percentage of lead, and the existence of mixed-crystals on either side of the eutectic composition.—A. H. C.

Uranium and vanadium [in ores]; Volumetric determination of —. E. D. Campbell and C. E. Griffin. J. Ind. and Eng. Chem., 1909, 1, 661—665.

THE method proposed is based on the facts that sulphur dioxide has no reducing action on uranyl solutions; and that the titration of vanadium solutions after reduction to the dioxide (V₂O₃) by zinc or aluminium and sulphuric acid requires three times the quantity of permanganate necessary for titration after reduction with sulphur dioxide. The vanadium solution after reduction with aluminium is received in a solution of a ferrie salt to prevent re-oxidation by air. From 0.3 to 0.5 gm. of the ore (e.g., a carnotite ore) is dissolved in 40 c.c. of sulphuric acid (1:5) or in a mixture of nitric and sulphuric acids. After evaporation till most of the acid (the whole of the nitric acid) is expelled, the solution is cooled, diluted, treated with excess of sodium carbonate, and then while boiling, hydrogen peroxide is added, drop by drop, until the iron is entirely in the ferrie condition. The solution is filtered, the precipitate washed with hot water, dissolved in the smallest possible quantity of sulphuric acid (1:1), and the solution treated with excess of sodium carbonate, boiled and filtered. The precipitate is washed, and the combined filtrates and washings are treated with sulphuric acid, so that an excess of 2—5 c.c. of the concentrated acid is present. The vanadium in the solution is reduced by a current of sulphur dioxide, the liquid boiled, and a rapid current of carbon dioxide passed through the boiling solution to expel the excess of sulphur dioxide. The hot solution is then titrated with permanganate of a strength not exceeding N/20. The solution (75 c.c.) is now placed in a 10-in. test-tube, into which a spiral of heavy aluminium wire is next introduced, heated to boiling, and the tube covered and placed in a boiling water bath. When the reduction is complete, as shown by the lavender or greyish colour of the solution, the tube is cooled, the spiral removed and rinsed with 50 c.c. of a solution containing 26 grms. of ferrie alum per litre of water slightly acidulated with sulphuric acid, which is allowed to run into the tube. The solution is now titrated with N/20 permanganate, being heated to 80° C. and a little sulphuric acid added, if necessary, near the end. The number of c.c. of permanganate minus three times the number of c.c. used in the first titration gives the number of c.c. required to oxidise the uranium from the dioxide (UO₂) to the trioxide (UO₃).—A. S.

Molybdenum: Determination of — in molybd. nite.
E. Collett and M. Eckardt. Chem.-Zeit., 1909, 33, 968—969.

THE following method gives accurate results in the analysis of molybdenite: 0.3 gram. of the sample is oxidised by digestion for 2—3 hours with 25 c.c. of fuming nitric acid. The liquid is then treated with 1—2 c.c. of concentrated sulphuric acid, and evaporated until white fumes appear; the residue is taken up with 50 c.c. of water, and the solution filtered whilst warm. The insoluble residue is washed with a little water, then with dilute ammonia, and finally again with water. The united filtrate and washings are treated with an excess of ammonia, iron and aluminium hydroxides are filtered off, the filtrate is evaporated to 150–200 c.c., and treated with hydrogen sulphide. Any precipitated copper sulphide is filtered off, and dilute hydrochloric acid added to the filtrate, which is then boiled. The precipitated molybdenum sulphide is filtered off; the filtrate is evaporated to dryness, ammonium salts are destroyed, and the small quantity of molybdenum usually present in the residue is precipitated as before. The two precipitates are finally ignited with sulphur in a current of hydrogen, and weighed as molybdenum disulphide, MoS_2 . Ignition of molybdenum sulphide or molybdic acid to molybdic anhydride yields low results. The sample used should be very finely powdered, the operation requiring 2—3 hours grinding, in order to ensure complete decomposition by the subsequent treatment with nitric acid.—A. G. L.

Metallographic observations in vacuo at high temperatures.
P. Oberhoffer. Metallurgie, 1909, 6, 554—567.

AN apparatus is described by means of which metals may be microphotographically examined while they are heated to high temperatures *in vacuo*, in order to determine the physical constants of the changes they undergo in special relation to their structure. The method previously employed has been to examine a large number of pieces of the metal or alloy, which have been subjected to various heat treatments usually at wide ranges of temperature, and it has not been possible to determine either the critical point of the change, or the velocity of formation of any special constituent at all accurately. With this apparatus these changes can be watched in one piece of metal. Instead of using a cinematographic outfit, as he intended, the author heated the specimen till a change was in progress, stopped the change by cooling *in situ*, and then photographed it; he then reheated to restart the change, and after an interval recooled and again photographed the stage to which the change had arrived, and so on to its completion. If desired, minute quantities of gases can be introduced into the vacuum, and the behaviour of the polished specimen examined under their influence;

hydrogen and chlorine were both utilised. The piece of metal suitably polished and etched, and in connection with a thermo-electric junction is held at the end of a quartz tube, 3x, (see fig.), around which is wound a platinum electric resistance, 2, for obtaining the necessary temperature. The quartz tube is itself held by a glass tube, 3, which is provided at the top with the necessary electric connections, 8 and 9, and is enclosed in a larger flat bottomed tube, 11, through which the observations are made, and which can be evacuated. A perforated platinum plate, 4, insulates the radiant heat from the quartz tube and the bottom of this outer glass tube. This latter is plated externally with electro-deposited copper, 11, and rests in a brass water cooler, 111., which is held by springs and suitable screws, 17, 18, to the stage of a Le Châtelier microscope. The author has studied with this apparatus the transformation of austenite to sorbite, but although the results are very promising, no definite statements can yet be made. With reference to the formation of temper-carbon it would appear that the eutectic is the main source of this constituent. Although the temperature of its initial formation is unknown, yet once such formation starts it becomes rapidly completed, and a low temperature is now effective in its completion. The presence of hydrogen increases the rapidity of its formation, but the effect on the temperature of its initial formation could not be determined. Thirty-two microphotograms illustrate the paper.—A. H. C.

Metals: Employment of ammonium nitrate in the analysis of —. L. Loviton. Ann. Chim. analyt., 1909, 14, 325.

SOME metals, *e.g.*, copper, zinc, nickel, are readily attacked by fused ammonium nitrate, whilst some others, such as iron, tin, and antimony, are not attacked at all, or only slightly. The author therefore recommends the use of fused ammonium nitrate in the analysis of certain mixtures of metals, *e.g.*, for the determination of iron in mixtures of this metal with copper, brass or nickel. A weighed quantity of the sample (2—4 grms.) is added to fused ammonium nitrate and the whole is heated until the reaction is complete. The mass is extracted with water, and the residual iron dried and weighed. The method is very expeditious and stated to be extremely accurate. (cf. Valentine's Practical Chemistry, 10th Edition, p. 197).—L. E.

Bismuth in New South Wales. Chem. and Drugg., Sept. 18, 1909. [T.R.]

THE quantity of bismuth (metal and ore) recorded as having been exported from New South Wales during 1908 is 8.75 tons, valued at £2,017, as compared with 16.35 tons, valued at £5,268, in 1907. The mines at Jingera, in the Pambula Division, owned by the International Mines, Ltd., were only in operation for a short period in the early part of the year, and the ore raised amounted to 12 tons. From the Kingsgate Mine, in the Glen Innes Division, 4 tons of concentrates, assaying 56 per cent. bismuth, were obtained. The bismuth in this mine is found in association with molybdenite. From 1880 to 1908 the total export has been 512 tons, valued at £121,899, the largest output in any single year being 55 tons 8 cwt. in 1905.

PATENTS.

Armour plate: Manufacture of —. S. O. Cowper-Coles, London. Eng. Pat. 11,142, May 22, 1908.

HARDENED steel balls, short lengths of steel tubing, or fragments of hardened steel or of carborundum are arranged in any suitable pattern, and an alloy of aluminium, with or without the addition of steel wire or ribbon, is cast about them. The plate so formed may be faced to withstand the action of sea water, by previously lining the mould with copper plates or the like, having projecting lugs to ensure perfect union; or zinc-coated iron plates may be used which form a hard superficial alloy with the aluminium.—F. R.

Steel; Process for the manufacture of — G. J. Stock, Darlington, England. U.S. Pat. 933,596, Sept. 7, 1909.

THE process is conducted in two stages, using a Bessemer converter in conjunction with a heat economiser. In the first stage the iron is melted in the converter by forcing fuel through the tuyères while the converter is in an inclined position, the products of combustion being passed through the economiser. The second stage is the ordinary Bessemer "blow," the air blast being preheated by passing through the economiser.—J. W. H.

Steel pieces; Simultaneous cementation and decarbonisation of different portions of — J. de Moya, J. A. Bernardini, and K. B. Greatbath. Fr. Pat. 398,858, April 4, 1908.

THE piece of steel is buried to a depth corresponding to the portion which is to be decarbonised, in a mixture of iron oxide and iron filings or in any other decarbonising composition. The portion intended for cementation is similarly covered completely with wood charcoal or other analogous material, this last being protected on the outside by a layer of some refractory earth well pressed down. The whole is contained within a metal casing, the layers of oxide and charcoal being kept separated by means of metal plates. In this state it is submitted to the necessary temperature in a cementation furnace.—C. A. W.

Blast furnaces; Method of drying the air required for — by calcium chloride, with concomitant automatic regeneration of the drying agent by the fumes of the hot air apparatus. F. A. Danbiné. Fr. Pat. 398,916, Jan. 28, 1909.

THE moist air from the blowing machine is passed through a receptacle containing anhydrous calcium chloride so that it emerges in an almost dry condition. After passage through a recuperating apparatus it is admitted through the tuyères of the blast-furnace in the usual way. In order to regenerate the calcium chloride, when this has become sufficiently charged with moisture, the process is reversed. The inlet through which the air arrives from the blowing machine, and that lying between the blast-furnace and recuperating apparatus, are closed, the chloride receptacle being placed in communication with a chimney. The exhaust gases from the furnace, together with sufficient air for their combustion, are admitted into the recuperating apparatus through separate ports in the base, and there allowed to burn. The hot products of combustion passing into the chloride receptacle carry away the adhering moisture and finally escape up the chimney. It is not necessary to provide a separate chamber for the chloride, which may be placed at the bottom of the recuperating chamber and there renewed as it becomes contaminated with ashes.—C. A. W.

Ores; Method of reducing — G. F. Rendall, New York, Assignor to American Reduction Co., New Jersey. U.S. Pat. 932,175, Aug. 24, 1909.

A REDUCING gas is brought into intimate contact with the ore-charge in a retort, the gas then passing into a chamber above the retort, into which heated air is also forced; the hot gases so produced are used to heat a subsequent charge of ore in a furnace communicating with the retort. The reduced ore from the retort is discharged into a closed receptacle from which the air has been exhausted. This receptacle is then sealed and cooled, after which the ore is mixed with any desired compound, and fused in a bath of molten metal.—A. G. L.

Copper ores; Process of leaching — G. C. Schneider, Freiberg, Assignor to E. Abresch, Neustadt a.d. Haardt, Germany. U.S. Pat. 932,643, Aug. 31, 1909.

COPPER ore (66 kilos.), which may previously be roasted, is treated with a solution consisting of 100 litres of water, 10 kilos. of sodium hydroxide, and 10 litres of glycerin or other organic substance capable of dissolving cupric hydroxide.—A. G. L.

Carbonate ores of copper and zinc; Metallurgical treatment of — V. E. Laurent. Fr. Pat. 398,812, Apr. 2, 1908.

THE pulverised carbonates of copper or zinc are mixed with chloride or sulphate of ammonium and heated in a reverberatory furnace. The ammonium carbonate which passes over is collected in water, the resulting solution being employed in the extraction of a further quantity of copper carbonate or calcined calamine. This second solution of copper or zinc is afterwards mixed with that obtained by the lixiviation of the sulphates or chlorides remaining on the hearth of the furnace after the previous distillation. The zinc or copper is immediately precipitated as oxide or carbonate. The carbonate of copper may then be mixed with an alkali or alkaline-earth acetate and heated to a temperature below 300° C. The resulting acetate of copper is itself decomposed when the temperature attains 300° C., with the production of metallic copper and regeneration of alkali acetate, the latter being separated from the metal by lixiviation.—C. A. W.

[Sulphide] Ores; Process of oxidising — B. E. Eldred, Bronxville, N.Y., Assignor to Combustion Utilities Co., N.Y. U.S. Pat. 932,689, Aug. 31, 1909.

SULPHIDE ores are oxidised by exposure to currents of air diluted with regulated amounts of fully burnt products of combustion, to which combustible gas (carbon monoxide) may also be added.—A. G. L.

Ores or other solid materials; Separation of crushed — from liquids. A. J. Arbuckle and A. Osborne. Fr. Pat. 400,626, March 8, 1909.

THE apparatus, which may be employed for the separation of crushed ores from cyanide solutions, or for analogous purposes, consists essentially of a depositing tank, 1, provided, in its upper part, with one or more layers of filters, 36, 37, 38, each series being composed of eight segmental chambers of decreasing sizes from the top to the bottom layer. The mixture of ore and liquid is fed into the apparatus through an opening, 67, below the lowest series of filters, but above the normal level of deposited solid. Each filter chamber is constructed so as to be readily removable and consists essentially of a segmental frame which serves as a support for the metallic gauze or perforated plate secured at top and bottom by exterior bands. Each of these chambers is provided with a three-way cock, 48, which communicates with the interior between the layers of filtering material. By this means the chambers may be thrown into communication with an aspirating pump, so that a more rapid motion of the liquid through the interstices of the filters is produced, or, conversely, a counter-pressure may be created when it is desired to remove any sediment from

the filtering material. The removal of the solid matter adhering to the filters is effected by means of radial scrapers, 58, which rotate on a vertical shaft, 51, passing down the centre of the apparatus. These scrapers, which are arranged so as to travel between the several layers of filter-chambers, are provided with one or more bands of thin metal which pass over the filtering surface and remove the deposited solid. At the bottom of the apparatus a series of chambers or compartments, 6, is constructed at the side. The sediment is distributed between these compartments by means of radial arms, 65, fixed on the lower part of the shaft, 51. Each compartment forms the lower part of a screw conveyor, 31, enclosed in a tubular casing, 24, and these conveyors provide for the removal of the residual ore at 30.—C. A. W.

Ores of precious metals; Treatment of —. Clancy Metals Process Co. Fr. Pat. 400,770, March 13, 1909.

THE pulverised ore is submitted to the action of a solution containing cyanide, a soluble iodide, and a substance capable of producing nascent oxygen in presence of the mixture, such as a soluble bisulphate, ozone, or nitrogen peroxide. The process is hindered if the solution be too strongly acid, but goes forward in feebly acid solutions. The most suitable proportions of the constituents must be determined by preliminary trials, but in practice the mixture may be composed as follows:—Potassium cyanide, 450 grms.; potassium iodide, 225 grms.; sodium bisulphate, 1350 grms.; lime or soda, 225 grms.; the whole dissolved in 900 kilos. of water and employed in the proportion of two parts of solution to one of ore. The same solution may be used over and over again provided the strength in cyanide and bisulphate be maintained constant. No further addition of iodide is necessary, the iodine being regenerated by the bisulphate added from time to time. Between each operation it is desirable to pass the liquid over zinc shavings in order to extract the dissolved metals. The bisulphate may be replaced by ozone or by nitrogen peroxide, the continuous regeneration of the iodine proceeding in an exactly analogous manner. Refractory ores containing reducing agents (such as iron sulphides) or tellurium may be treated at once by the solution, no preliminary roasting being necessary.—C. A. W.

Suspended matter from liquids containing mineral value; Process of separating —. P. J. A. Maignen, Philadelphia, Pa. U.S. Pat. 932,795, Aug. 31, 1909.

SUSPENDED matter is removed from a liquid containing mineral value (dissolved metals) by adding sodium carbonate and aluminium sulphate in such proportions as not to affect substantially the degree of alkalinity of the liquid. The reagents may be added in the form of solutions.—A. G. L.

Crucible-furnace. W. S. Rockwell, Assignor to W. S. Rockwell Co., New York. U.S. Pat. 932,906, Aug. 31, 1909.

THE furnace consists of a central crucible chamber, open at the top, and two combustion chambers placed on opposite sides of the crucible chamber, each combustion chamber being provided with a burner projecting downwards into the chamber. The crucible chamber is provided with a movable cover, and means are provided for tilting the furnace.—A. G. L.

Alloy; Antifriction —. E. A. Tonedda, Albany, N.Y. U.S. Pat. 933,139, Sept. 7, 1909.

THE alloy contains relatively large proportions of lead and cadmium and a relatively small proportion of magnesium; the proportion of lead is greater than that of cadmium. The alloy of cadmium and lead is said to be hardened by the magnesium.—J. W. H.

Metals; Annealing of —. E. M. D. Hirsch. Fr. Pat. 399,977, May 11, 1908.

THE non-oxidising atmosphere, in which the metal is annealed, is obtained by means of a current of nitrogen. The gas, which may be produced as a by-product in the manufacture of liquid air, is employed in preference to carbon dioxide in the treatment of iron alloys.—C. A. W.

Zinc oxide; Preliminary preparation of — with a view to its metallurgical treatment. H. Pape. Fr. Pat. 400,547, March 9, 1909.

THE metallurgical treatment of the voluminous zinc oxide obtained by condensation is extremely difficult. According to the present patent, the oxide is subjected to a high temperature, exceeding 1000° C., in a reverberatory furnace. After two to three hours' heating, the material is obtained in lumps and solid grains of which the apparent density may be as much as five times greater than that of the original substance. The product having been cooled, and crushed if necessary, may then be smelted for the metal in the usual way.—C. A. W.

Calamines; Method of calcining and simultaneously enriching poor —. J. L. Babé. Fr. Pat. 400,727, March 12, 1909.

AS ordinary reverberatory furnace is employed, provided with an upper and lower hearth, surrounded by a chamber in which the oxide fumes are condensed. The upper hearth or roasting table is charged with a mixture of carbon and calamine which is heated indirectly through the hearth, the temperature being raised to the point necessary for reduction by a current of air drawn through the surrounding chamber. The zinc oxide fumes as they are formed, together with the other products of roasting and combustion, are drawn over a mixture of calamine and zinc oxide on the lower hearth. By the production of zinc carbonate in this way, crude calamine ores may be enriched. Any oxide passing away is condensed in flannel bags in the upper part of the surrounding chamber.—C. A. W.

Volatile chlorides, especially those of heavy metals; Process for obtaining —. F. Prior. Ger. Pat. 212,215, April 13, 1907.

SULPHIDE or oxide ores or compounds of the metals are mixed with suitable chlorides and with a solid carbonaceous fuel, and heated by means of an air-blast to the desired temperature. The process may be applied to the separation of metals which form volatile chlorides from other metals, and also to the separation of metals which form chlorides of different degrees of volatility. For example, auriferous and argentiferous ores may be mixed with fuel and with sodium chloride, and treated in the way described. The volatilised chlorides of gold and silver are preferably passed into a condensing chamber containing metallic iron, on which metallic gold and silver are deposited.—A. S.

Tin contained in the liquors obtained by the treatment of tin-plate scrap with stannic chloride or ferric chloride, or mixtures of the two; Process for recovering the —. J. Perino. Ger. Pat. 212,757, Dec. 25, 1907.

THE liquors, which contain the tin in the form of stannous chloride, are oxidised by means of air, and simultaneously or subsequently heated, whereby a portion of the tin is precipitated as basic chloride, whilst the remainder is converted into stannic chloride: $3\text{SnCl}_2 + \text{O} + \text{H}_2\text{O} = 2\text{Sn}(\text{OH})\text{Cl} + \text{SnCl}_4$. The basic chloride is removed by filtration, dried, and heated to redness in a current of air, whereby, especially in presence of ferric oxide, it is decomposed into tin dioxide and chlorine. The tin dioxide may be reduced to metallic tin, whilst the chlorine may be utilised for the oxidation of the stannous chloride (or ferrous chloride) in a further quantity of the liquor.—A. S.

Iron; Copperising —. W. G. Clark, Geelong, Victoria. U.S. Pat. 932,964, Aug. 31, 1909.

SEE Eng. Pat. 16,820 of 1908; this J., 1909, 986.—T. F. B.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

(A.)—ELECTRO-CHEMISTRY.

Report of British Association Committee on electro-analysis. See XXIII. Inorg. Quant.

Electrolytic determination of thallium. Morden. See XXIII. Inorg. Quant.

PATENTS.

Batteries; Electric galvanic —. G. Schauli, London. Eng. Pat. 14,609, July 9, 1908.

THE negative element of the battery consists of a number of zinc plates, formed from pressed sheet zinc, which may or may not be corrugated on one side, the sheets being connected together by a cast zinc frame or zinc strips. The positive element consists of plumbago and charcoal or charcoal and manganese dioxide attached to a central carbon rod, and surrounded by a paste or mixture of ammonium chloride, other metallic chlorides or lime salts, and zinc chloride. The electrodes are placed in an electrolyte composed of "amylon," and exciting salts such as platinum ammonium chloride, zinc ammonium chloride, and alum.—B. N.

Conductors; Electric —. P. MacGahan, Pittsburg, Pa., U.S.A. Eng. Pat. 23,007, Oct. 29, 1908. Under Int. Conv., Nov. 8, 1907.

A CORE of suitable metallic conducting material, such as copper, surrounded by a different conducting material, such as aluminium, is drawn through rolls and dies until of the desired shape and size. The conductor is then passed through an electrolytic bath, capable of producing an insulating coating of aluminium oxide on the surface in the form of a thin film.—B. N.

Furnace; Electric —. J. A. Hay, London, Assignor to American Electric Furnace Co., New York. U.S. Pat. 932,469, Aug. 31, 1909.

THE crucible or hearth of the furnace is provided with a passage for limbs of the core and a winding or windings for the primary, the passage being furnished with a metallic shield having a radiation surface, in the form of ribs, of greater length than the axial diameter of the shield itself, the total area of the surface being greater than the normal surface area of the passage.—B. N.

Ozone; Process of producing —. J. F. Place, Glen Ridge, N.J. U.S. Pat. 932,898, Aug. 31, 1909.

COMPRESSED air is passed through a coil immersed in liquid oxygen which is thus evaporated, the air being cooled and liquefied. The vaporised oxygen, mixed with part of the cooled air, is conducted to an ozoniser, and the oxygen lost by evaporation is replenished by that of the liquefied air.—F. SOBY.

Electrodes of magnetic oxide of iron; Process for the production of —. P. Askenasy. Ger. Pat. 212,795, July 7, 1908.

A MIXTURE of finely divided iron and solid oxygen-yielding substances, such as chlorates or perchlorates, with or without the addition of a diluent (e.g., iron oxide) is brought to reaction in any suitable manner in a mould of the shape of the electrode it is desired to produce. The magnetic oxide of iron produced is melted by the heat of the reaction, and solidifies in the desired shape.—A. S.

Arc flames; Process for the production of quietly burning —. Kunheim und Co. Ger. Pat. 212,881, May 8, 1907.

WHEN a current of gas is passed through a conduit in which an arc has been produced, the arc travels along the electrodes in the direction of the gas current. If, however, a force of equal intensity be exerted in the opposite direction, a condition of equilibrium is attained, and the arc flame burns quietly. In such quietly burning arc

flames, the aureole, or decomposition zone, disappears almost entirely. The force opposed to the current of gas may be an electro-dynamic one, or the "driving power" of the hot gases from the arc may be utilised, *e.g.*, by leading the current of gas to be treated downwards through the reaction chamber. According to the present patent the intensity of one or of both of the opposing forces is made to decrease in the direction of its action; this may be effected for example by making the conduit in which the arc is produced of increasing cross-sectional area in the direction of flow of the current of gas. In this way, accidental variations in the intensity of the forces cause merely a displacement, but not destruction of the equilibrium.—A. S.

(B.)—ELECTRO-METALLURGY.

Ore analysis; Application of graded potentials to ——. D. F. Calhane and J. C. Woodbury. J. Amer. Chem. Soc., 1909, 31, 1048—1051.

THE following form of procedure was found to be useful for the analysis of ores containing much lead and smaller quantities of silver and copper, together with iron, aluminium, magnesium, and calcium. The actual ore used in the experiments was a carbonate. The electrolytic cell consisted of a platinum crucible weighing 45 grms., in which was placed concentrically a smaller crucible weighing about 16 grms. The smaller crucible was supported by a device made of a thread spool on the end of a wooden rod; contacts of thin copper secured in the lower end of the spool pressed it against the inner walls of the crucible, holding it in place and making electrical connection with the solution. The capacity of the space between the two crucibles was about 30 c.c. Two grms. of the ore were dissolved in nitric acid and any remaining free acid was neutralised. Thirty c.c. of nitric acid of sp. gr. 1.42 were then added, the solution was diluted to a volume of 250 c.c., and 25 c.c. of this solution were placed in the space between the two crucibles. With an E.M.F.

of 1.4 volts the silver was deposited in two hours. After the silver had been rinsed, dried, and weighed, the electrolysis was continued over-night at a pressure of 2 volts, the deposited copper and lead dioxide being then washed, dried, and weighed. The lead peroxide was dried at 160—180° C., the temperature being raised slowly and kept at the higher point for about 1 hour. During the last half hour of the silver deposition, it was necessary to keep the potential carefully at 1.4 volts to avoid resolution of silver by the nitric acid present.—W. P. S.

Steel; Treatment of — in electric furnaces. H. M. Howe. Eng. and Min. J., 1909, 88, 400—406.

THE author compares the results of steel production from pig iron in electric and other furnaces, particularly with reference to the removal of phosphorus and sulphur. In electric furnaces, the current is only utilised for the production of heat, the reactions being brought about in the usual manner by the addition of iron oxide, carbon, ferro-manganese, etc., the chief difference being that in the electric furnace, heat is supplied and may be maintained, without the introduction of oxygen or sulphur. Electric smelting, owing to its high cost, can only compete with the ordinary processes in the final stages of steel making, the molten pig iron being run into electric furnaces for the removal of impurities and for conversion into steel. Electric furnaces may be divided into three groups, *viz.*, arc, resistance, and combined arc and resistance furnaces, illustrations of which are given. In the Héroult and Stassano type of arc furnace, the current enters and leaves the furnace above the bath, and is liable to violent fluctuations owing to occasional short circuits caused by the making and breaking of the arc, especially during the boiling-up stage. In the Giffre and Girod type, in which the current enters above the charge and passes out through the bottom of the furnace, using the bath of metal as the lower electrode, this defect is minimised, at the possible expense of the furnace bottom. Of the resistance furnaces, the Kjellin furnace consists of an annular trough holding the molten metal, in which the current is induced by means of a central core. In the Roebling-Rodenhauser furnace, three cores and coils are used, the steel being heated in a narrow channel passing round the outside of them, and which is in connection with a central bath of the metal; a current also passes through the metal from electrodes buried in the walls. As the heat is generated in the metal, in induction furnaces, the slag, which is only heated by contact, tends to be insufficiently melted, and the rapid rotation of the metal, caused by the action of the current, retards the separation of the slag. In the Kjellin furnace, the narrow channel also renders the removal of slag difficult. On the other hand, there is no local overheating, as is the case in arc furnaces where the arc strikes the metal, and which may cause a certain amount of injury to the steel. Owing to the favourable deoxidising conditions subsequently obtainable in electric furnaces, dephosphorising can be carried on with rapidity by the free addition of iron oxide, but large amounts of phosphorus which require several successive slaggings could be more economically removed in ordinary furnaces. After oxidation of the phosphorus, the phosphatic slag is thickened with lime, or otherwise, and removed. After removal of the phosphorus, deoxidation is mainly accomplished by means of carbon, and when nearly all the iron and manganese oxides have been reduced, the carbon commences to reduce the lime, resulting in the formation of calcium sulphide, which passes into the slag: $C + (FeMn)S + CaO = CaS + FeMn + CO$. Owing to the absence of extraneous fuel, the steel can readily be almost completely desulphurised. A table is given of ten slags of greatly varying basicity, showing that, in the electric furnace, it is unnecessary for desulphurising slags to be strongly basic. Electric furnace steels are said to contain less hydrogen and nitrogen, it being suggested that the absence of the former may be due to the formation of acetylene or other hydrocarbons, owing to the presence of some calcium carbide, but the superiority of electric furnace steel over open-hearth steel is chiefly due to its greater freedom from slag and oxide.—F. R.

PATENTS.

Furnaces; Electric induction. — Röehling'sche Eisen- und Stahlwerke Ges.m.b.H. and W. Rodenhauser, Völklingen on Saar, Germany. Eng. Pat. 18,513, Sept. 3, 1908. Under Int. Conv., Feb. 26, 1908.

THE object of this invention is to reduce the magnetic dispersion which is produced in furnaces where the melting channel forms the secondary, at a relatively great distance from the iron core. The various members of the latter are composed of sheet metal laminae, which are considerably greater in width than the thickness of the assembled laminae, the core thus being of an elongated rectangular form in cross-section. The core comprises two vertical limbs, and two curved yoke-pieces abutting against the extremities of the vertical limbs, in such a way that the laminae of the vertical limbs and yoke pieces are continuous. The vertical limbs are arranged with their wider faces directed towards each other, and at such a distance apart as to afford a wide working hearth, the latter being formed by the union of the two annular channels, forming the secondary of the furnace, surrounding the vertical limbs of the core. The upper semi-circular yoke-piece is arranged in a horizontal plane, in order to give access to the working hearth, the lower yoke-piece being arranged in a plane containing the longitudinal axes of the vertical limbs, so that the latter and the yoke may be made in one piece.—B. N.

Furnaces; Electric induction. — The Gröndal Kjellin Co., Ltd., and J. Hårdén, London. Eng. Pat. 8194, April 5, 1909.

THE secondary of the furnace consists of a melting chamber in the form of an annular channel carrying the charge. This melting chamber or lining is composed of graphite or plumbago and a refractory binding material, such as fireclay, intimately mixed in such proportions, that, when starting the furnace, the primary current will induce currents in the chamber walls sufficiently strong to heat them and melt the charge by conduction. When the charge becomes a continuous conducting mass, the current will then flow through it in preference to the chamber walls. The latter may consist of almost pure graphite, containing only a small percentage of tar, molasses, or the like, when dealing with a charge of high melting point. The portions of the walls adjacent to the surfaces of contact with the charge, are enlarged, in order that these parts may carry a larger portion of the induced current. During the starting of the furnace, a portion only of the primary winding is connected across a source of constant voltage, and means are provided for putting the whole of the primary winding into the circuit when the charge is fused or heated sufficiently to become a continuous electric conducting mass. The inner surface of the melting chamber may be faced with a thin layer of magnesite or other suitable inert material, in order to avoid the introduction of carbon or silicon into the charge.—B. N.

[Pyritic] Smelting-furnace. S. B. Ladd, Washington, D.C. U.S. Pat. 931,775, Aug. 24, 1909.

THE furnace, which is intended for so-called pyritic smelting, consists of an elongated hearth containing molten matte, and provided with tuyères placed above the normal level of the bath. A conduit extends between this hearth and a fore-hearth at the level of the elongated hearth. A current of electricity for heating the matte is passed between an electrode placed in the fore-hearth and a second electrode placed in the elongated hearth. The fore-hearth is provided with a tap-hole, through which molten material is continuously removed.—A. G. L.

Furnace; Electric — for the fusion and reduction of ores. Aktiebolaget Elektrometall. Fr. Pat. 400,244, Feb. 25, 1909. Under Int. Conv., March 10, 1908.

THE ore charge is introduced through a central opening in the upper part of the furnace, which is of such an internal form, that free spaces always exist between the inclined upper surface of the material and the masonry

of the furnace. The electrodes penetrate the material in these free spaces, so that the heat is developed principally in the interior of the mass, and the masonry of the furnace is consequently protected against the elevated temperature existing in the zone of fusion. The material may be charged through an inclined rotating tube, the lower end of which fits into the opening in the top of the furnace. In an alternative form, a blast of air is introduced at the bottom of the inclined tube, in order to burn the escaping gas for the purpose of calcining the material, but in this case a separate hopper must be provided for the introduction of the reducing material, such as carbon. The arrangement is suitable for use with a polyphase current.—B. N.

Oxides and the like; Method of reducing and melting. — O. Frick, Sheffield, England. U.S. Pat. 932,459, Aug. 31, 1909.

THE material to be treated is successively introduced between electrodes in such a manner as to form a continuous conductor of "high-resistant" material. The material is reduced by causing an alternating current to flow through the "high-resistant" conductor; the reduced material falls into an annular crucible and is melted by an electric current induced in the substance within the crucible.—B. N.

Galvanising rods, tubes or the like; Electro-galvanising apparatus specially applicable for. — G. A. Beckett, Seacombe, Cheshire. Eng. Pat. 24,467, Nov. 14, 1908.

THE electrolytic bath is fitted with upper and lower anodes, and with a series of sprocket wheels, the latter being adapted to propel the rods or tubes between, and in proximity to, the anodes, and along an inclined supporting contact rail which forms the negative electrode. After leaving the last wheel, the rods or tubes are raised from the bath by a lifting device, consisting of an endless chain carrying arms which engage with the rods. Brackets fixed to the top of the tank, carry girders, from which the axes of the sprocket wheels are supported by means of suitable brackets. Vertical screws, engaging in the girders, are attached below to the upper anode, so that the height of the latter may be adjusted by turning the screws. The sprocket arms are fixed to a hinged detachable rim, which may be rapidly bolted in position on the periphery of the wheel.—B. N.

Zinc sulphate solutions to be used for the electrolytic separation of zinc; Process for removing iron from — by means of peroxides and zinc oxide. Siemens und Halske Akt.-Ges. Ger. Pat. 213,004, April 12, 1908.

MANGANESE dioxide is used for the oxidation of the iron contained in zinc sulphate solutions, with a view to the subsequent precipitation of the iron with zinc oxide. The manganese dioxide is regenerated during the electrolytic separation of the zinc from the purified solution.

XII.—FATTY OILS, FATS, WAXES, AND SOAPS.

Animal fats; Detection of some — in admixture with other animal fats by Polenske's method. L. Laband, Z. Unters. Nahr. Genussm., 1909, 18, 289—299.

From an experimental examination of Polenske's method of detecting animal fats in admixture with other animal fats by means of the difference between the melting and solidification points (this J., 1907, 1148; 1908, 1119), the author concludes that if the directions are closely followed, concordant figures may be obtained by different workers. The "difference value" obtained with different kinds of beef fat ranged from 13.65 to 14.85, the highest value being thus slightly higher (0.15) than that recorded by Polenske. A sample of fat extracted from salted American beef gave a value of 13.10, and a sample of tallow oil a value of 14.20. The "difference values" of 9 samples of lard of different origin ranged from 19.35 to 20.60, and thus fell within the limits given by Polenske (19—21). A sample of lard containing 10 per cent. of beef tallow gave a difference value of 18.60, but it was not possible to detect the presence of 5 per cent. of beef tallow, the "difference value" of the mixture in that case being 9.65, and thus within the limits for pure lard. The variations of the values given by 100 samples of pure butter fat differed considerably from the figures given by Polenske, the following results being obtained:—Russian butter, 11.50 to 16.80; Dutch butter, 16.00 to 16.65; Danish (imported) butter, 12.80 to 14.50; and Danish butter, 12.05 to 15.50. In the author's opinion the method is only valuable as a test of the purity of butter when it confirms the results of other tests, indicating adulteration. In the case of butter with medium or high saponification and Reichert-Meißl values, a high difference value cannot be regarded as a proof of adulteration.—C. A. M.

Thermal [Mauméné] test of solid fats determined by means of the thermocometer. M. Tortelli. Gaz. chim. ital., 1909, 39, II., 71—100.

THE author describes the use of the thermocometer (this J., 1904, 668) for determining the thermal (Mauméné) value of oils and fats. Tables are given showing the Mauméné values of mixtures of different oils and fats with paraffin oil, and of mixtures of olive oil with other fatty oils; the Mauméné values of animal oils at different temperatures, and of solid fats; and the ratios between the Mauméné values and iodine values of the principal oils and fats. (See also this J., 1909, 250.)—A. S.

Development of fat in the black walnut. McClenahan. See XXIV.

German East African wax. Chem. and Drugg., Sept. 18, 1909. [T.R.]

THE trade in beeswax received its impetus in 1905 from the southernmost coastal district, Lindi. The Tabora district is the chief centre both of production and of trade, and can be depended upon for a regular supply of over 50 tons of wax per annum. The total value of wax exported in 1907 amounted to £73,567, as against £44,405 in 1906. Of this increase £24,328 is accounted for by the lake ports, chiefly Muanza. The following were the quantities exported during the years 1905-6-7:

To	1905.	1906.	1907.
United Kingdom cwt.	14	1	117
Germany (three*) "	6,174	4,746	7,519
Zanzibar "	1,635	439	1,113
*Rest of Africa "	3,322	2,135	4,710

* To Europe via Uganda Railway.

PATENTS.

Fluid or semi-fluid substances [fats, margarine-emulsions, soaps, etc.]; Cooling apparatus for —. E. V. Schou, Southall, Middlesex. Eng. Pat. 1160, Jan. 16, 1909.

THE apparatus consists of two cooling rollers placed parallel and close to each other and rotating in opposite directions. The molten fat to be cooled is delivered into a V-shaped channel fitted above and between the rollers. This channel is constructed of non-conducting material, or its walls may be hollow so that hot water may be passed through them. A slot along the lower part of the channel allows the fat to flow between the rollers, the object being to keep the fat, etc., in a hot and molten state up to the moment when it is delivered on to the rollers, where it is immediately cooled.—W. P. S.

Fat; Process and apparatus for rendering — in an open boiler. G. Hönneke. Ger. Pat. 242,797, Jan. 18, 1908.

THE melting chamber is surrounded by a steam jacket and the latter is in turn surrounded by an annular clarifying chamber. The crude fat is introduced into the lower half of the melting chamber; the heavier impurities settle to the bottom and are withdrawn from time to time through a pipe, whilst the fat rises to the top, and overflows, through a filter, into the annular clarifying chamber.—A. S.

Lubricating compounds; Manufacture of —. J. E. Gill, Franklin, Pa. U.S. Pat. 932,855, Aug. 31, 1909.

A "COMPOUND OF LEAD" is heated with animal oil so as to form a homogeneous liquid; a solid animal fat is added, and, when cold, the mass is mixed with petroleum oil.—W. P. S.

Oils; Process for nitrating vegetable or animal —. F. Gehre. Fr. Pat. 398,748, Jan. 25, 1909.

ANIMAL or vegetable fats and oils, or mixtures of the same with other oils and solvents, may be converted into solid products by treating them with sulphuric acid, then with water, and afterwards with a nitrating mixture of sulphuric and nitric acids. The essential feature of the invention is the preliminary treatment with sulphuric acid and water. The products may be used in the preparation of explosives and in dyeing.—W. P. S.

Soap; Toilet cleaning —. R. Lyon, Englewood, N.J. U.S. Pat. 932,152, Aug. 24, 1909.

SOAP (one part) is incorporated with heavy precipitated chalk (two or more, preferably 3 to 5, parts).—C. A. M.

Wax-extracting apparatus. E. Köpke, Honolulu, Hawaii. U.S. Pat. 931,878, Aug. 24, 1909.

THIS apparatus consists of an open vessel divided into two communicating compartments by means of a partition. Into one of these is introduced the receptacle containing the material to be extracted, and means are provided for keeping it in position. The receptacle has a hood-shaped top provided with a spout, beneath which is a screen covering the material contained in a cage.—C. A. M.

XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, &c.

(A.)—PIGMENTS, PAINTS.

Red lead; Physico-chemical and technical investigation of — J. Milbauer. Chem.-Zeit., 1909, 33, 950—951, 960—961.

CONTINUING his experiments on the formation of red lead from lead oxide (this J., 1909, 612), the author shows that the rapidity of rotation of the reaction tube in which the lead oxide (3.7 grms.) was heated in a current of oxygen for 3 hours at 470° C.) exerted a considerable influence on the reaction. Thus, with 130 revolutions per minute, the product contained 12.3 per cent. of red lead; with 75 revolutions, 18.4 per cent.; with 30 revolutions, 19.4 per cent.; with a stationary tube, 18.7 per cent. It is probable that these results are due to the fact that a high speed of rotation causes the lead oxide to ball together and thus to expose a smaller surface to the gas. Mercier Ann. des Mines, 1871, 19, 212) stated that agitation of the lead oxide is superfluous; in practice the mass is stirred, however, to ensure even heating. All the following experiments were carried out in a stationary tube. It was found that preheating the gas was practically without influence on the reaction. The influence of impurities was then studied: with conditions under which pure lead oxide gave a red product containing 19.1 per cent. of red lead, an addition of 1 per cent. of hydrogen or the oxygen gave 19.6 per cent. (red); 5 per cent. of nitrogen monoxide gave 18.1 (red); steam gave 19.8 (red); nitric acid vapour gave 5.96 (yellowish-brown); moist ammonia gave 2.6 (brown); 0.1 per cent. of sodium hydroxide added to the lead oxide gave 18.5 (intensely ed); 1 per cent. of sodium hydroxide gave 17.5 (intensely ed); 0.1 per cent. of lead nitrate gave 21.8 (fine pink); 0 per cent. of silver nitrate gave 20.8 (red); 10 per cent. of copper nitrate gave 20.6 (red); 0.1 per cent. of bismuth nitrate gave 17.6 (brownish); 10 per cent. of bismuth nitrate gave 17.7 (brownish); 0.1 per cent. of cobaltous nitrate gave 19.5 (brownish); 10 per cent. of cobaltous nitrate gave 10.9 (black); 10 per cent. of zinc nitrate gave 8.5 (pink); 0.1 per cent. of zinc nitrate gave 19.2 (pink); 0.1 per cent. of sodium nitrate gave 20.9 (red); 1 per cent. of sodium carbonate gave 18.0 (bright red); 1 per cent. of silica gave 17.9 (light red); 1 per cent. of barium sulphate gave 15.7 (light red); 1 per cent. of lead sulphate gave 15.5 (light red); 1 per cent. of iron oxide gave 15.7 (light red); 1 per cent. of antimony oxide gave 5.5 (light red); 1 per cent. of aluminium oxide gave 7.2 (light red); 1 per cent. of calcium oxide gave 16.5 (light red); 1 per cent. of arsenious oxide gave 15.5 (light ed); 1 per cent. of lead chloride gave 17.4 (light red); 1 per cent. of tin oxide gave 16.9 (light red); 1 per cent. of ammonium vanadate gave 17.3 (light red); 1 per cent. of ammonium platinochloride gave 21.6 per cent. (light ed); words in parentheses represent the colours of the products. Addition of 50 per cent. of finely divided silica reduced the yield of red lead from 19.1 to 1.5 per cent.; 70 per cent. of finely-divided carborundum to 2 per cent.; 90 per cent. of barium sulphate to 16.0 per cent.; addition of coarse carborundum was without effect. Formation of red lead from lead carbonate proceeds much more rapidly than from lead oxide, a maximum of 89.9 per cent. being attained after 3 hours' heating, which was not increased after 7 hours' heating, at the most favourable temperature of 470° C.—A. G. L.

Lithopone; Analysis of — J. S. Remington and C. Smith. Caoutchouc et Gutta-Percha, 1909, 6, 3259—3262.

THE following methods of analysing lithopone are suggested as being rapid, exact, and applicable to any sample. The sample is first tested for the presence of water-soluble salts of iron, zinc, calcium, and barium. A separate portion is tested for barium carbonate, the percentage of the latter being determined if necessary. For the determination of the barium sulphate and zinc sulphide, 0.5

gram. of the sample is mixed with 25 c.c. of water at 40° C.; 0.5 gram. of bromine is added, the containing flask is covered with a watch-glass, and set aside for one hour, during which it is occasionally agitated. Ten c.c. of concentrated hydrochloric acid are then added, and the excess of bromine is expelled by heat. 25 c.c. of water are next added, and the contents of the flask are boiled and filtered; the residual barium sulphate is washed, dried, ignited and weighed. The filtrate from the preceding operation is precipitated by barium chloride, and the barium sulphate is similarly separated and weighed. From this weight, the percentage of zinc sulphide in the sample is calculated. For the determination of the total zinc, 0.5 gram. of the sample is treated with hydrochloric acid, and the zinc is precipitated as carbonate, from which the total percentage of zinc oxide is obtained. The weight of zinc oxide corresponding to the zinc sulphide previously found, is deducted from the weight of total zinc oxide, the difference giving the percentage of zinc oxide present as such. If barium carbonate was found in the preliminary examination, the corresponding weight of barium sulphate must be deducted from the total weight of barium sulphate (estimated as such). The weight of barium sulphate corresponding to the barium carbonate, must also be added to the weight of the barium sulphate corresponding to the zinc sulphide. If salts of iron, calcium or barium, are present, the zinc must be separated by ammonia and ammonium sulphide. The following table shows the composition of twelve samples of lithopone of average quality, obtained from the English market, the analyses having been carried out by the above methods.

Lithopone sample.	Barium sulphate.	Zinc sulphide.	Zinc oxide.	Barium carbonate.
No.	per cent.	per cent.	per cent.	per cent.

Precipitation of sulphuric acid as barium sulphate. Sacher. See XXIII., Inorg. Quant.

PATENTS.

Oil inks; Processes and apparatus for recovery of ingredients of — M. S. Hopkins and C. R. Barnett, Baltimore, Md. U.S. Pats. 932,470, 932,548, 932,549, and 932,550, Aug. 31, 1909.

THE material, e.g., cloth, containing the oily ink, is washed in a closed chamber with a volatile solvent, such as acetone, the solution is passed through a filter-press to recover the pigment, and the volatile solvent is recovered from the solution of the oily vehicle by distillation. The solution of the oily ink may be mixed with a chemical capable of forming a solution or emulsion with the volatile solvent, and with a reagent capable of producing a precipitate which carries down with it the pigment, before passing into the filter-press. The vessel in which the treatment with the volatile solvent is performed, the filter-press, and the still in which the solvent is expelled, are all connected to a condenser and a vacuum pump, in order to facilitate the recovery of the solvent.—A. S.

Coloration process. B. D. Avis, jun., Wallace, W. Va. U.S. Pat. 933,522, Sept. 7, 1909.

THE surface to be coloured, preferably after being varnished, is coated thinly with mercurous nitrate, and then exposed to ammonia gas.—A. S.

Pigment; Green — and process of making the same.
F. F. Hunt, New Brighton, N.J. U.S. Pat. 932,864,
Aug. 31, 1909.

FRESHLY-PRECIPITATED ferric hydroxide is suspended in water, and treated first with a quantity of acid less than that equivalent to the hydroxide, and then with a ferrocyanide in amount equivalent to that of the acid. The product is a dark green pigment, homogeneous in colour, and free from gritty matter.—A. S.

Painting; Substitute for oil for use in —. N. Silvestrini.
Fr. Pat. 398,813, April 2, 1908.

A SOLUTION of rosin (15 grms.) in 90 per cent. alcohol (30 grms.), to which is added about 40 per cent. (by vol.) of turpentine oil.—A. S.

Fireproof paint; Manufacture of a —. H. Terrisse and C. Collignier. Fr. Pat. 398,956, Jan. 30, 1909.

A MIXTURE of ammonium-magnesium phosphate and suitable pigments is made into a paint with a vehicle prepared by dissolving linoleates or resinates of metals such as calcium, lead, etc., in a suitable solvent. The paint is fireproof owing to the property of ammonium-magnesium phosphate of evolving ammonia at 150° C.—A. S.

Carbon; Process for the preparation of finely-divided amorphous or crystalline —. M. Gollmert. Ger. Pat. 212,202, Nov. 1, 1907.

SUCH mixtures of hydrocarbons with carbon dioxide or carbon monoxide, alone, or diluted with other gases, as cannot be exploded under pressure at the ordinary temperature, are heated to a suitable temperature before ignition. The most suitable temperature and pressure must be determined by experiment. As an example, a mixture of equal parts of ethylene and carbon dioxide cannot be exploded at the ordinary temperature even when under a pressure of 12 atmospheres, but if heated to 400° C., explosion can be effected at a pressure of 6 atmospheres. In order to increase the force of the explosion, a certain quantity of oxygen or air may be added to the gaseous mixture.—A. S.

Soot; Process for the production of — by decomposition of hydrocarbons. J. Machtoff, K. Bosch, F. Closs and T. and C. Boehm. Ger. Pat. 212,345, June 14, 1908.

THE hydrocarbon mixture is introduced, in the form of a spray, into a jacketed decomposition chamber, heated by means of superheated steam or the like. It is rapidly gasified in this chamber and heated to such a degree that it can be ignited by means of an electric spark or by mercury fulminate. Means may be provided whereby the introduction of the hydrocarbon mixture into the decomposition chamber and the production of the electric spark follow one another automatically. Instead of heating the decomposition chamber, a small quantity of a gas such as acetylene, of great explosive force, may be added to the hydrocarbon mixture.—A. S.

Pigments containing naphthanthraquinone and its derivatives. Badische Anilin und Soda Fabrik. Fr. Pat. 400,632, March 9, 1909. Under Int. Conv., Sept. 3, 1908, and Feb. 10, 1909.

Colouring matter for use as a pigment. Eng. Pat. 17,546. See IV.

(B).—RESINS, VARNISHES.

Resinous exudation of Aleppo pine (Pinus halepensis). M. Vèzes. Bull. Soc. Chim., 1909, 5, 931—933.

SAMPLES of the resinous exudation of *Pinus halepensis* (Algeria and S. France) have been examined, and the results compared with those obtained by Tschirch and Schulz (Arch. Pharm., 1907, 245, 156) and by Tsakolotos (Archimedes, 1908, No. 1) who studied resins from Greece, likewise derived from *P. halepensis*. It was found that at least four-fifths of the oil of turpentine extracted from

P. halepensis consist of almost pure *d*-pinene. As a raw material for the production of the latter hydrocarbon or of its derivatives, this oil is thus superior to American oil of turpentine. The American oil often consists of a mixture of dextro- and levo-rotatory oils, having at the most, a specific rotatory power $[\alpha]_D$ —lower than 30° whereas the products from *P. halepensis*, obtained from various samples, gave, on an average, $[\alpha]_D=47^\circ$.—E. C. V.-E.

PATENTS.

Article-coating process [with tung oil]. J. M. Talmadge. Brooklyn, N.Y. U.S. Pat. 933,598, Sept. 7, 1909.

THE article is coated with a film of raw tung oil, alone or mixed with a hydrocarbon, and then heated to at least 212° F. for not more than 30 minutes, whereby the oil is converted into an insoluble form, which is stated to be resistant to water, chemicals, fire, heat, and electricity.—A. S.

Linoxyn and similar products, intended for the manufacture of linoleum; Preparation of —. A. Genth. Fr. Pat. 398,804, Jan. 23, 1909. Under Int. Conv., Feb. 26, 1908.

IT is stated that the superiority of Walton's linoxyn to the linoleum obtained by the rapid process is due to the fact that in the latter process, the linseed oil is oxidized uniformly throughout, whilst Walton's product consists of a colloidal solution of linoleum in boiled oil. According to the present patent, a product equal to Walton's linoleum is obtained from linoleum prepared by the rapid process by intimately mixing it with linseed oil or boiled oil preferably with the aid of heat and with access of oxygen.—A. S.

(C).—INDIA-RUBBER, &c.

Rubber; Method for studying the process of hot-vulcanisation of —. E. Stern. Z. Elektrochem., 1909, 15, 660—661.

THE method proposed, is one in which vulcanisation is effected by heating together rubber and sulphur in naphthalene solution. It was found that the alteration in the freezing-point of naphthalene brought about by the solution in it of rubber, and by the subsequent heating of the solution, were too small to allow of deductions being made. When vulcanisation was carried out in naphthalene solution, the freezing-point was raised, but here again the changes were too small to allow of the process being followed by this method. By adopting the analytical method the process can be readily followed. In carrying out this method, however, the samples taken at intervals from the heated solution must be run into acetone, and not allowed to cool down and solidify, before extraction with acetone. In the latter case it is found to be impossible to remove all free sulphur by extraction; in the former case extraction is readily effected. The results obtained are shown in the following table, in which columns 1 and 2 refer to a solution of 4.98 grms. of Para rubber and 6 grms. of sulphur in 90 grms. of naphthalene, vulcanised at 150° C., the samples being allowed to solidify before extraction; and columns 3 and 4 to a solution of 5 grms. of Para rubber and 9 grms. of sulphur in 90 grms. of naphthalene, vulcanised at 150° C., the samples being run directly into acetone without cooling.

PATENTS.

Vulcanised rubber; Machine for reducing — to powder.
T. Gare, New Brighton, Eng. Pat. 22,893, Oct. 28, 1908.

The apparatus consists of: (1), a rotary grinding cylinder, having a detachable rasp- or grater-like grinding surface, consisting of a band of "stabbed" steel, the ends of which are drawn down a slit in the periphery of the cylinder and are there gripped by a suitable device; (2), a spiked roller, adjacent to the grinding cylinder, which together with a series of spring- or weight-influenced "presser feet," above and in line with it, forms a set of independent automatic feeds, notably for such articles as disused wheel tyres.—E. W. L.

Chewing gum [from pontianak rubber]; Manufacture of —.
J. D. Darling, Philadelphia, U.S.A. Eng. Pat. 186, Jan. 4, 1909.

A LOW-GRADE rubber, obtained from Borneo and known under the trade name of "pontianak," or "gutta-jelutong," is boiled with a solution containing 25 lb. of sodium hydroxide in 100 galls. of water, until all the impurities present in the rubber have settled to the bottom. The mixture of rubber and resin is then removed from the surface of the solution, washed, and kneaded in a suitable machine at a temperature of 200° to 300° F. until the whole mass has become plastic and ductile. The product thus obtained contains about 3 parts of resin to 1 part of rubber and is suitable for use as a chewing gum. About 5 per cent. of a vegetable wax may be added during the kneading operation.—W. P. S.

Rubber; Solution for and method of extracting resin from —.
C. P. Flora, Watertown, Mass., Assignor to Hood Rubber Co., Boston, Mass. U.S. Pat. 933,638, Sept. 7, 1909.

THE rubber is extracted successively with alcohol, a mixture of benzol and alcohol, and alcohol again.—A. S.

Indianrubber goods; Manufacture of —.

XIV.—TANNING, LEATHER, GLUE, SIZE.

Mangrove swamps of the Philippines; The economic possibilities of the —.
R. F. Bacon and V. Q. Gana. Philippine J. Sci., 1909, 4, A, 205—210.

ALL the species of mangrove trees of the eastern tropics, which are used commercially for tanning purposes, around in the Philippine Islands. Limited areas, amounting

altogether to about 28,000 hectares (70,000 acres), have been mapped out by the Forestry Bureau, which it is estimated will yield about 230,000 tons of bark; the total area occupied by the mangrove swamps is very much greater than this. The best barks (from Mindanao) contain only about 23—25 per cent. of tannin, and cannot compete with East African barks (containing 50 per cent. of tannin), if imported into the United States as raw material. It would be profitable to prepare catechu in the Philippines and ship this to the United States, if the tannin were allowed to enter free of duty, which is not the case at present. Apparently catechu can be prepared very easily from the bark, extraction with cold water, followed by evaporation to dryness *in vacuo* of the extract being all that is necessary.—A. G. L.

Tannin of the bark of Eucalyptus occidentalis (mallet bark).
J. Dekker. Collegium, 1909, 273, 281, 290, and 297.

FROM the results of experiments upon mallet-tannin (see this J., 1909, 665) the author concludes that fractional precipitation from a neutral solution is the only way of obtaining relatively pure tannins. When tannins are acetylated in the ordinary way, water is simultaneously removed; the product does not contain acid groups. In the process of benzoylation in an alkaline liquid, considerable oxidation takes place. Heating the tannin with zinc dust and sodium hydroxide solution gives better results than the ordinary method of fusion with potassium hydroxide.—C. A. M.

Methylotannin; Characteristics of —.
J. Herzig and V. Renner. Monatsh. Chem., 1909, 30, 543—554.

THE authors have prepared methylotannin from pure tannin, and have obtained preparations with the same elementary composition and methoxyl values (37.2 to 37.9) as previously recorded by Herzig and Tscherne (Ber., 1905, 38, 989). The optical activity, however, showed considerable variations, though the preparations still showed almost the same methoxyl values. Thus a compound with $[\alpha]_D = 7.0^\circ$ had a methoxyl value of 37.22, and another with $[\alpha]_D = 16.05^\circ$ had a value of 37.78. In the authors' opinion this variation in the specific rotation is not conclusive proof that methylotannin is not a chemically individual substance. When boiled with an aqueous solution of potassium hydroxide, methylotannin yields triethyl- and diethyl-esters of gallic acid in proportion corresponding to about 86.5 per cent. of the original substance. The mixture of these derivatives is optically inactive. According to the elementary composition and methoxyl values, the triethyl ester predominates, the ratio probably being as 4:2. The other compounds formed in the decomposition were not identified.—C. A. M.

The Leathersellers' Technical College.
Times Eng. Suppl., Sept. 29, 1909.

THE new Leathersellers' Technical College in the Tower Bridge Road, which was opened on October 1st, forms a most important addition to the technical schools of London.

THE buildings and machinery cost £20,000. There is a general laboratory for 40 students, a research laboratory for ten students, a bacteriological laboratory, and a special room for microscopy and microphotographic work. There is also a large museum containing samples of tanning materials from all parts of the world, and of leather and skins, showing the imperfections due to faulty manipulation in tanning or brought about by peculiarities of growth, method of preservation employed, damage by insect pests, branding, and other causes. In the lecture theatre, with accommodation for 100 students, it will be possible by means of a new electroscope projector to show on a screen a view of any specimen of leather, thereby enabling illustrations of grain defects, flaws, or other special features of the sample to be shown without the necessity of photographic reproduction.

ON the ground floor are two experimental tanneries. The adjoining dye house will deal with the product of the tanneries, and also with the re-dressing and dyeing of foreign tanned skins. Adjoining the dye house is

the machine room, provided with machines for scouring, glazing, rolling, and currying. The plant is driven by three powerful electric motors. In the basement is the boiler which provides the steam for the vats and hot water for the dye house, and also supplies the heating apparatus for the building; while on the third floor two spacious drying rooms have been erected for the drying and stoving of the finished leather, a curriers' shop permitting practical demonstrations of the currying of all classes of leather. The library in the entrance hall contains a complete collection of books dealing with the leather and allied industries, as well as the standard works on chemistry, &c.

The curriculum consists of a two years' course, divided into three sections to suit either heavy leather or light leather tanners, or those who only dress and finish tanned leather. The course of instruction in the evening classes extends over three years. The principal of the college is Dr. J. Gordon Parker.

PATENTS.

Waste sulphite liquor; Treatment of — and the manufacture of a new product [tanning material] therefrom. J. Y. Johnson, London. From J. S. Robeson, Au Sable Yorks, N.Y., U.S.A. Eng. Pat. 17,956, Aug. 26, 1908.

THE new product consists of a soluble compound of the sesquioxide of chromium or aluminium with the practically unchanged organic matters of sulphite cellulose liquor, and is prepared by treating the liquor with aluminium or chromium sesquioxide and an acid capable of precipitating mineral matter from such liquor, and removing the precipitate thus formed. After standing some time, the liquor deposits a second precipitate, of sulphur, which is also removed. The solution is then concentrated or evaporated to dryness. The product is stated to be useful as a tanning material.—S. H.

Tanning hides and skins, and mordanting fibrous materials, and the obtaining of improved products thereby. J. Y. Johnson, London. From J. S. Robeson, Au Sable Yorks, N.Y., U.S.A. Eng. Pat. 17,957, Aug. 26, 1908.

THE method consists in treating hides and skins, in successive baths of increased concentration, with a liquor containing a compound of the sesquioxide of aluminium or other base with the practically unchanged organic matters of waste sulphite liquors (see preceding abstract). The tanning can be completed in this liquor, or it can be finished by any of the ordinary tanning processes. The patent also covers the treatment of cotton, wool, and other fibrous materials with the same liquor.—S. H.

Hides, skins and leather; Treatment of —. J. S. Robeson, Au Sable Yorks, N.Y., U.S.A. Eng. Pat. 17,958, Aug. 26, 1908.

THE processes consist of: (1), the treatment of hides or skins with a tanning agent, followed by a bath containing sulphite liquor (see preceding abstracts) and finally bleaching with an acid or other bleaching agent; (2), the tanning of hides or skins by means of sulphite liquors and bleaching with an acid or other material; and (3), tanning the hides or skins in sulphite liquors and subsequently bleaching by the use of sulphuric acid and a salt which reacts with the acid to effect the bleaching.—S. H.

Filling or stuffing material [from gelatin]; Manufacture of —. R. A. Caldwell, New Southgate, and F. Pfeffermer and Pneumatic Syndicate, Ltd., London. Eng. Pat. 11,300, May 12, 1909.

A MIXTURE of gelatin and glycerin, together with zinc oxide or other insoluble powder is heated to about 70° C., and then stirred or beaten into foam with the aid of a current of air, first at the ordinary pressure and later under increased pressure. It is next subjected to the action of a

tanning agent, preferably a solution of pyrogallol rendered viscous by addition of glycerin, gelatin, or the like, and the stirring continued until a product of the required consistence is obtained. The stirrer is electrically driven, so that by means of a watt-meter, it is possible to determine at any moment the power consumed. The air may be mixed with inert gases or with oxygen, and the tanning agent may be mixed with substances which retard its tanning action. The product is suitable for filling hollow tyres, cushions, etc. A. S.

Artificial bathur and process of making the same. L. V. Guillebeau-Chaput, Paris. U.S. Pat. 933,645, Sept. 7, 1909.

Condensation product of catechin and catechu-tannic acid [for silk weighting, tanning, etc.] Fr. Pat. 401,108. See V.

XV.—MANURES, &c.

Phosphoric acid; Determination of — in mineral phosphates. G. Jørgensen. Analyst, 1909, 34, 392—393.

THE following method devised by the author is now the official process in Denmark for the analysis of fertilisers and mineral phosphates:—*Reagents*:—(a). *Molybdic solution*.—300 c.c. of a solution of 100 grms. of pure ammonium molybdate in 280 c.c. of ammonia solution (sp. gr. 0.97) are poured into 700 c.c. of nitric acid (sp. gr. 1.21) with vigorous stirring, and the mixture left for 24 hours. (b). *Acid ammonium nitrate solution*, prepared by mixing 90 c.c. of nitric acid (sp. gr. 1.4) with about 1500 c.c. of water, adding 80 c.c. of ammonia solution (sp. gr. 0.91), and diluting the mixture to 2000 c.c. (c). *Magnesia solution* consisting of 50 grms. of pure magnesium chloride ($MgCl_2 \cdot 6H_2O$) and 150 grms. of ammonium chloride in 1000 c.c. of water. *Method*:—Five grms. of the mineral phosphate are gently boiled with 20 c.c. of nitric acid (sp. gr. 1.21), and the solution cooled and made up to 250 c.c., and filtered. To 50 c.c. of the filtrate are added 165 c.c. of the molybdic solution, and the flask immersed in a water-bath at 50° C. for 10 minutes, its contents being meanwhile occasionally stirred. After cooling, the liquid is filtered and the precipitate washed 10 times by decantation with the acid ammonium nitrate solution, about 20 c.c. being used each time. The calcium in the filtrate is determined by adding sulphuric acid and alcohol to the extent of twice the volume of liquid. The washed molybdic precipitate is dissolved in 100 c.c. of 2.5 per cent. ammonia solution, and the filter washed 8 times with about 10 c.c. of the ammonia solution, so that the final volume is about 180 c.c. The beaker is covered with a glass, its contents heated to the boiling point, and (after removal from the flame) treated with 30 to 35 c.c. of the magnesia solution, added drop by drop from a burette, with continual stirring. The beaker is then covered again, and the stirring continued until the precipitate becomes crystalline, after which it is allowed to stand for at least 4 hours, and then collected in a platinum crucible packed with spongy platinum. It is next washed with 2.5 per cent. ammonia solution until free from chlorides, dried, heated gradually over an Argand burner, and finally ignited strongly, cooled, and weighed. The presence of a small amount of silica does not interfere with the results. In the presence of much organic matter a more energetic solvent than nitric acid must be used. The chance of precipitating arsenic or silicic acid is reduced, as the excess of molybdic solution added is smaller than in the case of other methods. It is necessary to avoid too long a boiling before the precipitation, since loss of ammonia will cause the precipitation of the magnesium ammonium phosphate to be incomplete.

For the analysis of artificial manures the quantities of reagents used are as follows:—

	For 50 c.c. of an aqueous extract of an 18 to 20 per cent. superphosphate (1 grm. of material).	For 100 c.c. of a 2 per cent. citric acid extract of 12 to 15 per cent. Thomas phosphate (1 grm. of material).
Molybdc solution	c.c. 75	c.c. 100
Ammonia	100	75
Magnesia	15 to 20	12 to 15

—C. A. M.

Phosphoric compounds: Manurial values of various organic —. K. Asō and T. Yoshida. J. Coll. Agric., Imp. Univ., Tokyo, 1909, 1, 153—161.

HAVING regard to the extended use of vegetable manures, such as green manure, rice-bran, oil-cake, straw, etc., in Japan, the authors have compared the manurial value of various organic and inorganic phosphorus compounds. The soil was a humus loam of a slightly acid reaction, which was exhausted by continuous cultivation without any manures for seven years. The pots having been manured with acidic manures, ammonium sulphate and potassium sulphate; or with basic manures, sodium nitrate and potassium carbonate; equivalent quantities of various phosphoric compounds were added, *viz.*, sodium phosphate, lecithin, phytin, nuclein, aluminium phosphate, ferric phosphate, and tricalcium phosphate. Barley was sown in these pots, its growth noted, and its weight ascertained when harvested; whence it appeared that lecithin produced the best results. Tricalcium phosphate also exerted a very favourable influence. The manurial value of phytin was far less than that of sodium phosphate, but almost equal to that of ferric and aluminium phosphate. As for nuclein, the experiment was made with basic manures only, as it is soluble in alkalis but not in acids; and its manurial value was very small. But while the manurial value of lecithin is far greater than that of phytin or of nuclein, the content of lecithin in plants is generally very small, while that of phytin is much larger. Hence the inferior value of phosphoric acid in vegetable manures

phytin, and as this compound is easily transformed in soils into insoluble ferric and aluminium phosphate, it is recommended to use vegetable manures in a putrefied state to render the phosphoric acid available. In the analysis of manures it is absolutely necessary to pay attention to the different organic phosphorus compounds.—R. C. P.

Phosphoric acid in organic manures; Different forms of —. S. Tsuda. J. Coll. Agric., Imp. Univ., Tokyo, 1909, 1, 167—170.

THE author has determined the amounts of the different forms of phosphoric acid in several organic manures of vegetable and animal origin. To determine the lecithin, 50 grms. of the air-dry sample were extracted with ether and the residue boiled with absolute alcohol. After evaporating the combined extracts to dryness, the residue was fused with potassium nitrate and sodium carbonate, and the fused mass dissolved in nitric acid. The phosphoric acid was then determined by the molybdate method. The residue obtained from the alcoholic extraction was dried and extracted with 500 c.c. of 0.2 per cent. hydrochloric acid at the room temperature. After filtering, the extraction was repeated. To a part of the acid extract, ammonia was first added until the reaction was slightly alkaline, then nitric acid in excess, and the phosphoric acid in the form of inorganic salts was determined by the molybdate method. To determine the phosphoric acid in the form of phytin, another part of the acid extract was evaporated in a large platinum basin and the residue was fused with potassium nitrate and sodium carbonate. After extracting the fused mass with nitric acid, the phosphoric acid was determined. The difference between the total and the inorganic phosphoric acid of the original hydrochloric acid extract is the phosphoric acid in the form of phytin. The residue left after extraction with 0.2 per cent. hydrochloric acid was dried and extracted with 500 c.c. of 5 per cent. hydrochloric acid in the same manner as before, and the phosphoric acid in the solution, in the form of both organic and inorganic compounds, was determined. The last residue was dried and fused with the fusion mixture, dissolved in dilute nitric acid, and the molybdate method applied to determine the phosphoric acid in the form of nuclein. The results obtained are shown in the following table:—

In 100 parts of dry matter.

	Soy bean cake.	Rape seed cake.	Red clover hay (before flowering).	Herring guano.	Bone dust (steamed).	Pressed cake of pupa of silk-worms.	Crab shells.
Total phosphoric acid	1.311	2.251	0.554	4.470	25.060	1.350	3.23
Phosphoric acid extracted by ether and alcohol (as lecithin)	0.114	0.091	0.050	0.310	0.023	0.043	0.023
Phosphoric acid extracted by 0.2 per cent. hydrochloric acid	0.050	0.050	Trace	1.894	5.534	1.039	0.300
Phosphoric acid extracted by 5 per cent. hydrochloric acid	0.040	0.073	0.300	0.860	Trace	Trace	0.151
Phosphoric acid in last residue (as nuclein)	0.120	0.931	0.084	0.648	0.530	Trace	0.200
	0.236	0.204	0.050	0.583	0.112	0.169	0.302

to that in animal manures is explained by these results. The phytin used in the experiments was prepared by extracting rice-bran in succession with ether and 95 per cent. alcohol, drying the residue, and extracting it with 0.2 per cent. hydrochloric acid. From the acid solution the phytin was precipitated with 95 per cent. alcohol, washed with alcohol and ether, and purified by dissolving in 0.2 per cent. hydrochloric acid and reprecipitating with alcohol. It was a white powder containing 45.86 per cent. of phosphoric anhydride. The nuclein was prepared from beer yeast and contained 1.68 per cent. of phosphoric anhydride. The lecithin contained 7.75 per cent. of phosphoric anhydride. A second series of experiments showed that rice-bran and rape-cake exert a better manurial effect after the fat has been extracted, and that the chief manurial value of phosphoric acid in press-cakes is due to phytin. The most essential phosphorus compound in vegetable manures is thus seen to be

These results show distinctively the difference between animal and vegetable manures in the relative amounts of the different forms of phosphoric acid, the former containing it mostly in the form of inorganic compounds and the latter as organic compounds. In vegetable manures phosphoric acid is present principally in the form of phytin, and the amount of nuclein is comparatively small; lecithin is also contained in small quantities, the phosphoric acid in this form being always less than 10 per cent. of the whole. On the other hand, since tricalcium phosphate is the principal ingredient of bones, most of the phosphoric acid of animal manures containing bones is the part soluble in 5 per cent. hydrochloric acid. In crab shells the phosphoric acid is in nearly the same form as in bones; while in the pupa of the silk-worm, *Bombyx mori*, it is present in an inorganic form easily soluble in 0.2 per cent. hydrochloric acid.

—R. C. P.

Herring-guano: Availability of phosphoric acid in various forms in —. R. Mitsuta. J. Coll. Agric., Imp. Univ., Tokyo, 1909, 1, 163—165.

Eleven pots, each containing 2.5 kilos. of a humus-loam soil, were manured with 2 grms. of potassium carbonate and 3 grms. of sodium nitrate, these large doses being necessary to eliminate the effect of the potash and nitrogen of the herring-guano. One pot was used as a control, one was treated with 5 grms. of herring-guano in its original condition, five pots with the same quantity of herring-guano after treatment with different solvents, and one pot with a quantity of sodium phosphate containing an amount of phosphoric acid equal to the total phosphoric acid of the 5 grms. of herring-guano. The results showed that treatment with ether and alcohol had not increased, but decreased the manurial value of the herring-guano, owing to the fact that the material had originally been deprived of most of its oil content, and it was chiefly lecithin, perhaps from lecithalbumin, which had been extracted by the ether and alcohol. The guano was much less effective after extraction with 0.2 per cent. hydrochloric acid than before. Since the content of phytin in herring-guano is very small, the phosphoric acid soluble in dilute acid was probably chiefly calcium phosphate. Nuclein in herring-guano has no immediate manurial value as generally assumed. The principal part of the phosphoric acid serving as phosphatic manure in fish-guano is of inorganic nature, chiefly consisting of calcium phosphate. Lecithin and phosphates soluble in water also exert a certain rôle. There is thus a great difference regarding the manurial value of phosphoric acid in animal and vegetable manures. (See preceding page.)—R. C. P.

Diacyandiamide as a nitrogenous manure. R. Inouye. J. Coll. Agric., Imp. Univ., Tokyo, 1909, 1, 193—196.

Five pots containing 8 kilos. of air-dry soil were each manured with 10 grms. of superphosphate and 5 grms. of potassium carbonate. In addition, equal quantities of nitrogen were applied to each pot, except Pot V., which received no nitrogenous manure. Pot I. served as control, and contained the total nitrogen as ammonium sulphate; Pot II., two-thirds of the total nitrogen as ammonium sulphate and one-third as diacyandiamide; Pot III. received the manure in the same proportion as Pot II., but the diacyandiamide was given as top-dressing later on; in Pot IV. the total nitrogen was applied as diacyandiamide. Experiments with rape and barley showed that early in the growth of the plants, the diacyandiamide exerted an injurious effect, the growth being impeded and the leaves turning a yellowish-white colour and withering. Later on, these adverse symptoms disappeared, and when harvested, the plants in Pots II. and III. excelled the plants in the control pot. The best results were obtained from Pot III., where the diacyandiamide was given as a top-dressing. The conclusion arrived at by the author is as follows:—Diacyandiamide may be injurious to the plants, but if the dose does not surpass a certain limit, it acts rather beneficially upon them; and it is, indeed, a better manure than ammonium sulphate. The plants in Pot IV., which received diacyandiamide as the only nitrogenous manure, were as much injured as those in Pot V., which received no nitrogen. One gram of nitrogen in the form of diacyandiamide for 8 kilos. of soil is injurious to the crops and especially to the young plants, but 0.35 gm. of nitrogen in the same form yields a favourable result. If diacyandiamide is applied as manure, it is better to use it as top-dressing.—R. C. P.

Diacyandiamide; Manuring with —. K. Asō. J. Coll. Agric., Imp. Univ., Tokyo, 1909, 1, 211—222.

Numerous experiments with calcium cyanamide have shown that in many cases this nitrogenous manure is equal or nearly so to sodium nitrate or ammonium sulphate. On acid muck (swamp) soils and on sandy soils, however, less favourable results have been obtained. Acid soils should first be neutralised with lime before "lime-nitrogen" is applied. Further it is advisable to avoid mixing "lime-nitrogen" with superphosphate. In the case of soils not only rich in lime, but also containing much more lime than magnesia, the lime content of the soil would be unduly

increased by the application of "lime-nitrogen," and the results would not be so good. Hence it has been proposed to separate the lime from the cyanamide. When the crude "lime-nitrogen" is treated with warm water, a separation takes place into cyanamide and calcium hydroxide; and the cyanamide readily polymerises to diacyandiamide. Comparative experiments as to the effect of diacyandiamide on the growth of buckwheat, oats, and paddy-rice under varying conditions in flasks, pots, and frames, showed that in water culture, diacyandiamide at a concentration of 0.01 per cent. is a source of nitrogen for plants. In common soil, it acts poisonously when used at the rate of 5 grms. per 10 kilos. of soil, but serves as a favourable nitrogenous manure with reduced quantities. In paddy soil the injury is less than in the soil of common dry land, and when the precaution is taken to perform the planting three weeks after manuring with diacyandiamide, no injury whatever is observed, and the harvest reaches nearly that obtained with the equivalent quantity of ammonium sulphate or of "lime-nitrogen." This renders it very probable that the bacteria in paddy soil convert the injurious diacyandiamide into innocuous compounds (ammonium compounds?) more rapidly than those in common field soil. Furthermore, diacyandiamide acts as a nitrogenous manure more favourably when applied in conjunction with alkaline manures.—R. C. P.

PATENTS.

Fertiliser; Process of making —. J. H. Connor, Nashville, Tenn. U.S. Pat. 931,846, Aug. 24, 1909.

Five parts of powdered phosphate rock or calcium phosphate, 1 part of caustic soda, and 2 parts of quicklime are mixed with water to the consistence of thick mud, and the mass heated strongly until the phosphoric acid becomes "available."—A. S.

Pyrophosphates [for fertilisers]; Process and apparatus for transforming the salts of tribasic phosphoric acid into —. E. Giana. Fr. Pat. 398,792, Jan. 12, 1909. Under Int. Conv., June 30, 1908.

A mixture of sulphate and pyrophosphate is formed by the action of sulphur dioxide, at a high temperature, and in the presence of atmospheric oxygen, on a salt of tribasic phosphoric acid, according to the equation: $2\text{Ca}_3(\text{PO}_4)_2 + 2\text{SO}_2 + \text{O}_2 = 2\text{CaSO}_4 + 2\text{Ca}_2\text{P}_2\text{O}_7$, in which the calcium salt is taken as an example. The operation may be carried out in a furnace which is described, in the lower part of which pyrites is burnt, whilst the upper portion consists of a muffle for the decomposition of the phosphate, above which are channels for the deposition of dust. The product has the following advantages over ordinary superphosphate:—It is dry and pulverulent and does not tend to harden; it is not acid, is readily distributed, and contains more phosphoric anhydride than superphosphate; moreover, there is no danger to the workpeople engaged in its preparation.—F. Sonn.

Calcium phosphates; Process of enriching —. C. Bardy. Fr. Pat. 398,924, Jan. 29, 1909.

In the treatment of phosphatic chalks by the sugar process, the mineral is calcined to convert the calcium carbonate into quicklime, and the latter is dissolved out of the product by means of a sugar solution. According to the present patent, the separation of the calcium sucrate solution from the residual calcium phosphate is effected in a centrifugal machine, instead of by the methods (decantation, filtration, etc.) usually employed. The sucrate solution is then treated with carbon dioxide, and the precipitated calcium carbonate separated from the saccharine solution also in a centrifugal machine.—A. S.

Organic nitrogenous manures; Process for the manufacture of —. H. E. L. Fiévet. Fr. Pat. 400,661, June 16, 1908.

NITROGENOUS organic matter, such as excreta of animals, slaughterhouse residues, etc., is mixed with small quantities of manganese dioxide, or other oxygen-yielding compound, the double sulphate of iron and magnesium, and magnesia, alumina, or tricalcium phosphate. It is

then infected with an alkaline culture of brewers' yeast, and allowed to ferment. The whole of the nitrogen is transformed into ammonia, which is fixed by the double sulphate of iron and magnesium. When the fermentation is completed, the mass is mixed with an absorbent material such as peat, neutralised with sulphuric acid, treated with ozonised air, and then dried in a stove. The yeast culture is composed of 30 grms. of dried brewers' yeast, 2 grms. of urea, 20 grms. of soda crystals, 1 grm. of potassium phosphate, and sufficient urine to make up 1 litre.—A. S.

Superphosphates; Method of and apparatus for removing — from decomposition chambers. K. J. Beskow, Helsingborg, and M. Ekedahl, Limhamn, Sweden. Eng. Pat. 4494, Feb. 23, 1909. Under Int. Conv. March 2, 1908.

XVI.—SUGAR, STARCH, GUM, &c.

Beetroot; Optically active non-sugar in the —. A. Blau. Deutsche Zuckerind., 1909, 34, 743—744.

To avoid the error in the analysis of beetroot juice due to the presence of certain optically active non-sugar substances, Herles has proposed boiling the juice with lime (see this J., 1908, 1168). The author shows, however, that though lower polarimetric readings are thus obtained than by the ordinary method, the quantity of optically active non-sugar destroyed by boiling with lime is quite small, and insufficient to account for the differences.

—L. E.

Sugar analysis; Proposals for unification of methods of clarification in —. F. Sachs. Internat. Comm. for uniform methods of sugar analysis, London, 1909; Z. Ver. deut. Zuckerind., 1909, 775—778.

THE author proposes that for determining invert sugar in sugar products (both cane and beet), normal lead acetate should be used for clarifying the solution, as recommended by Schrefeld (see this J., 1908, 1168). The use of unclarified solutions is objected to on the ground that the results may be vitiated by the presence of foreign matter in the copper or copper oxide. In accordance with Browne's recommendation, the author also proposes that Herzfeld's modification of Clerget's method should be used for the analysis of cane products. On the assumption that the volume of the lead precipitate affects the polarisation, Gonnermann has proposed the following method of clarification with a view to avoiding this error:—28.6 grms. ($=26 \times 1.10$) of the sample are dissolved and made up to 100 c.c. This solution is then made up to 110 c.c. either with 2–3 c.c. of alumina cream and 8–7 c.c. of water, or with 10 c.c. of a 3 per cent. solution of basic lead acetate, mixed, filtered, and polarised in a 200-mm. tube. The author points out, however, that the total volume of liquid will be less than 110 c.c. Hence the method does not effect the object in view.—L. E.

Sugar analyses; Basic lead nitrate as a clarifying agent in —. F. Herles. Internat. Comm. for uniform methods of sugar analysis, London, 1909; Z. Ver. deut. Zuckerind., 1909, 782—783. (See this J., 1897, 67.)

THE author's clarifying agent, basic lead nitrate, presents the following advantages:—It decolorises the solution well, and owing to its insolubility, the excess of the clarifying agent, under the conditions in which clarification is executed, does not cause the precipitate formed to partially dissolve, nor does it affect the polarisation reading. The alkali nitrate formed when basic lead nitrate is used (unlike the alkali acetate formed when basic lead acetate is employed) has no influence on the precipitate formed, but, on the contrary, precipitates any lead salt from the solution; again, the alkali nitrate has less influence than the alkali acetate on the polarisation. Solutions clarified with basic lead nitrate can be used directly for inversion, since, not only do they contain very little lead, but on adding hydrochloric acid, no weak

acid of feeble inverting power is liberated, as is the case, when, owing to clarification with basic lead acetate, alkali acetate is present. The clarified solutions filter quickly, yielding filtrates which are clear and remain so for a long time. The author recommends basic lead nitrate as a clarifying agent not only for molasses, osmose water, after-products, etc., but also for raw, first-product sugars.

Sugars; Colour reactions of —. Reactions of Pettenkoffer and Seliwanoff. J. Ville and E. Derrien. Bull. Soc. Chim., 1909, 5, 895—901.

It has been frequently stated that Pettenkoffer's reaction (purple coloration given by sucrose in presence of cholic and sulphuric acids) and Seliwanoff's reaction (red coloration produced by levulose in presence of resorcinol and hydrochloric acid) are due, not to the sugars, but to furfural. The authors find, however, that the colorations given by furfural are not identical spectroscopically with those produced by the sugars. The two reactions mentioned are really due to methyl-4-hydroxy-2-furfural, produced by the hydrolysis of the sugars. Pure methyl-4-hydroxy-2-furfural gives colorations identical both chromoscopically and spectroscopically with those produced by sucrose and levulose in the reactions mentioned.

—E. C. V. E.

Carbohydrates of plant seeds. E. Schulze and C. Godet. Z. physiol. Chem., 1909, 61, 279—351.

THE authors have investigated the nature and proportions of the carbohydrates in the kernels (i.e., dehusked seeds) and husks of a considerable number of seeds. The chief results are as follows:—*Seed kernels.*—No pentose or hexose was found in any of the seed kernels. Sucrose is of wide occurrence; thus, out of 27 kinds of seeds examined, in only two (blue and yellow lupins) was sucrose not found, and perhaps even in these seeds, sucrose is present in quantities too small to be isolated. Water-soluble carbohydrates which yield galactose on hydrolysis, appear to be as widely distributed as sucrose. The only hexoses which are formed by the hydrolysis of the water-soluble carbohydrates (di- and poly-saccharides) of the seed kernel are dextrose, galactose, and levulose; in no instance was mannose detected. The content of water-soluble pentosans is very small; in no case was so much as 1 per cent. found, and in some cases, none. Since there is no doubt that the water-soluble carbohydrates (including amylan, levulin, sinistrin and levosin, which are found in amylaceous seeds and which yield dextrose and levulose on hydrolysis) serve as reserve materials, and that before they are utilised by the growing shoot, they are transformed into dextrose, levulose, and galactose, it appears that the latter are specially adapted to the nutrition of the young plant. The hemicelluloses appear to be of universal occurrence in the kernels of seeds; in seeds that are free from starch and poor in fat, the hemicelluloses are present in considerable quantity in the kernels and in such cases they serve as reserve material. On hydrolysis, the hemicelluloses yield mixtures of hexoses (in many cases galactose and in others, mannose, is formed in considerable quantity) and generally a pentose, e.g., arabinose; the proportion of pentose, however, is much less than that of hexose. The cell walls of the kernels of the seeds examined contain a small quantity of cellulose. *Seed- and fruit-husks.*—These materials contain very little water-soluble carbohydrates, and little or no starch; they consist chiefly of nitrogen-free substances, insoluble in ether, water, and malt extract, and contain a considerable quantity of hemicelluloses. On hydrolysis, the hemicelluloses from various seed- or fruit-husks were found to yield arabinose or xylose, or both, and in many cases, galactose. The residue from the husks left after removal of the hemicelluloses by hydrolysis, was found to contain a substance soluble in 5 per cent. sodium hydroxide and possessing the properties of "wood gum" (xylan); the material left after removing this substance yielded cellulose. The husks also contain lignin in considerable amount, and most of them contain brown-coloured substances of unknown nature.—L. E.

Sugars; Relation of pyridine to the —. C. Nenberg. *Biochem. Zeits.*, 1909, 20, 526—530.

THE view that under natural conditions, carbohydrates are converted into cyclic substances and the latter into the sugars, finds much acceptance. Chemical evidence, however, is scanty, and the author's experiments in this direction have not hitherto led to very satisfactory results. He has already investigated the formation of furfural by the dry distillation of inositol (*Biochem. Zeits.*, 1908, 9, 551). He now finds that on oxidising pyridine with hydrogen peroxide and ferrous or ferric sulphate in sulphuric acid solution, a pentose or pentose derivative is formed, though he has not yet succeeded in isolating such a substance. On heating the reaction-product with sulphuric acid, furfural is formed.—L. E.

Gums; Enzymes in acacia and other —. F. Reimter. *Z. physiol. Chem.*, 1909, 61, 352—392.

THE author has investigated the enzymes of a number of gums, including hard and soft Kordofan gums, a very pure gum presenting the properties of a soft Kordofan gum, and a rather crude Gheziri gum. His experiments on the distribution of the gum enzymes and the behaviour of these enzymes towards poisons and high temperature, lead to the conclusion that very probably at least three enzymes, *viz.*, an oxydase, a peroxydase, and a diastase, are present in gum, though in some gums, all three enzymes may not be present. The diastase appears to be a mixture of at least two enzymes, of which one dissolves starch and converts it into erythro-dextrin, whilst the other forms sugar (*cp.* Fränkel and Hamburg, this J., 1906, 945). *Oxydase*.—The gum oxydase very much resembles Bertrand's laccase (this J., 1894, 1071; 1895, 374) and the author proposes to designate it by this name provisionally. A gum of strong oxidising power was found to contain not more than a very small trace of manganese, and to effect its oxidising action in acid solution, so that Dony-Henault's chief arguments against the existence of oxydases are invalid unless the presence of iron is regarded as responsible for the oxidising action (this J., 1908, 823). Tyrosinase was not found in any of the gums examined. The oxydase-activity was found to vary with different gums, and to be absent in some cases. *Peroxydase*.—This enzyme was present in all the gums examined excepting tragacanth. *Amylase (diastase)*.—The author shows that gum amylase acts on starch paste with the formation of dextrin and maltose, and not of the former only as was supposed by Wiesner and Grafe. According to Wiesner, his "gum ferment" can convert cellulose into gum, and according to Grafe, this enzyme, though incapable of acting on cellulose, converts hemicellulose-like substances and starch into dextrin. The author shows, however, that gum amylase does not attack ungelatinised potato starch, and that it only completely liquefies the gelatinised starch when the concentration of the latter is less than 5 per cent.; subsequent addition of water to the cold starch paste does not alter its behaviour towards the amylase, thus showing that the action of the latter is determined by the degree of hydrolysis of the starch. Again, gum amylase neither liquefies nor saccharifies insoluble gums or plant mucilages, and the author concludes that it is impossible that this enzyme, or the oxydase and peroxydase accompanying it, can convert cellulose or hemicelluloses into gum. Different varieties of gum differ widely in respect of amylase-content, and the proportions of the enzymes of which the amylase consists also vary; gum amylase presents very great similarity to malt diastase. According to Grafe, the saccharification of starch by the gums is caused, not by the enzymes of the latter, but by bacteria, and he found that on filtering the gum solution through a Pukal filter, the filtrate obtained possessed no saccharifying power. Fränkel and Hamburg observed that malt diastase passes through a Pukal filter nearly quantitatively if the enzyme solution is not rich in those colloids which remain in the filter and adsorb the enzyme. A gum solution, however, is very rich in colloids, and the author shows that on passing such a solution through the filter, a large proportion of the colloids is retained, and that the saccharifying part of the amylase may either be completely or almost

completely retained whilst the liquefying part passes through. The author also shows, contrary to Grafe's statement, that ether (recently purified) does not extract an enzyme from gum capable of converting starch paste into erythro-dextrin, since the ethereal extract contains no substance capable of acting on starch paste, and the residual gum saccharifies the paste quite normally; Grafe's result appears to have been due to the use of unpurified ether. The fact that the bark and wood of trees contains amylase (*cp.* Butkewitsch, this J., 1908, 822) easily explains the presence of amylase in gum, and the presence of oxydase and peroxydase in gum is traceable to the same source.—The author shows that the frothing exhibited by a gum solution when shaken, is not due to enzyme action as supposed by Wiesner, since this property is not destroyed or diminished by heating the solution; the property is really due to the viscosity of the solution.—L. E.

XVII.—BREWING, WINES, SPIRITS, &c.

Hops; Chemistry of —. R. Siller. *Z. Unters. Nahr. u. Genussm.*, 1909, 18, 241—271.

THE researches of Hayduck have shown that hops contain three resins, two of which, the soft α - and β -resins, are bitter principles soluble in light petroleum spirit, while the third, or γ -resin, is tasteless and insoluble. He also prepared from the two soft resins crystalline compounds of the corresponding α - and β -hop bitter acids. The author finds that the α -bitter acid can be precipitated quantitatively from a methyl alcohol solution of the mixed resins by lead acetate dissolved in methyl alcohol. As the lead salt of the α -bitter acid is decidedly soluble in excess of the precipitant, it is advisable to use only a 1 per cent. solution of lead acetate. After a recrystallisation from glacial acetic acid, the lead salt contains 36.65 per cent. of lead and is sufficiently pure to yield, after decomposition with dilute sulphuric acid, a well crystallised preparation of the free acid. Based upon this precipitation of the lead salt of the α -acid, the author has elaborated a method for the estimation of the three resins in hops as follows: (1), an ether extract gives the total resins, $\alpha + \beta + \gamma$; (2), a petroleum spirit extract gives the α - and β -resins, the γ -resin being insoluble in petroleum spirit; (3), the α -resin is determined by precipitation as lead salt from a methyl alcohol solution of 1 or 2; (4), the β -resin is determined by difference between 2 and 3; and (5), the γ -resin is determined by difference between 1 and 2. This method is claimed to give results correct to about 0.2 per cent. The α -acid, when pure, proves to be much more resistant to oxidation than it is usually considered to be, being practically unaltered in air at ordinary temperature; on protracted heating it absorbs oxygen and is resinified. The γ -resin appears to be a mixture of two substances differing in their solubility in ether and their carbon content. The α -acid has at least two pairs of doubly linked carbon atoms, as it yields a tetra-bromo addition compound.—R. L. S.

Hops; Determination of moisture in —. J. F. Hoffmann. *Woch. f. Brau.*, 1909, 26, 460—461.

IN a previous paper (this J., 1903, 655) the author described a method for the estimation of moisture in different substances by distilling with turpentine oil at a temperature of above 135° C. He finds that the method then described gives too high values and has consequently modified it by using a mixture of 400 c.c. of turpentine oil and 100 c.c. of toluene in the apparatus described in

this J., 1902, 1088. Figures are given showing that the new method yields results agreeing well with those obtained by drying *in vacuo* over phosphoric anhydride or for four hours in an oven at 80° C.—R. L. S.

Peptolytic ferments; Detection of —. E. Adlerhalden and A. Schittenhelm. *Z. physiol. Chem.*, 1909, 61, 421–425.

The authors criticise the various methods at present used for the investigation of the action of proteolytic and peptolytic ferments upon polypeptides. They suggest the use of a polypeptide yielding a large proportion of a difficultly soluble amino-acid, e.g., tyrosine, leucine, or cystine, the polypeptide itself being freely soluble in water. Glycyl-L-tyrosine is shown to be suitable. They have also prepared a peptone ("Pepton Roche") from silk, which is easily soluble in water, and contains a large proportion of tyrosine groups. It is prepared by the partial hydrolysis of silk, and after purification, is obtained as a snow white powder giving a colourless aqueous solution. For experimental purposes a solution is made of 10–15 per cent. strength, and sodium bicarbonate is added to the slightly acid solution to give a weak alkaline reaction. The solution which must be quite clear, is then added to the test ferment and placed in an incubator. If peptolytic ferments are present, tyrosine separates after a short time, and on cooling may be filtered off and weighed. The silk peptone should also be useful for the cultivation of bacteria. Further researches are in progress to obtain peptones in a similar way from other proteins, in order to obtain general experimental material for researches on peptolytic ferments.—W. N. B.

Alcoholic fermentation in the presence of sulphurous acid. P. Martinand. *Comptes rend.*, 1909, 149, 465–467.

THE fermentation which commences sooner or later in musts and sugar solutions containing considerable quantities of sulphurous acid is due to a micro-organism similar to the *Torula*; this organism has feeble fermentative powers, does not ferment maltose, and does not form ascospores. In one experiment which is described, 5 grms. of sulphurous acid were added to a solution of 180 grms. of sucrose in 1 litre of water; this commenced to ferment at the end of 10 days. At this time about one-half of the added sulphurous acid was present in the free state, the other half being combined, probably with the aldehyde which is produced by the organisms. Twenty-four hours later, all the free acid had disappeared, whilst 4.09 grms. were present in the combined state. The amount of aldehyde now present was 1.14 gm. per litre. An experiment with yeast in a similar sugar solution did not lead to the formation of aldehyde, and, consequently, fermentation did not commence. A portion of the added sulphurous acid becomes oxidised to sulphuric acid and it is only when the sulphurous acid has disappeared, either by oxidation or by combination with the aldehyde produced during the fermentation set up by the above-mentioned organisms, that the yeast cells grow and predominate.—W. P. S.

"*Tanezu*" (*Japanese vinegar ferment*); *The micro-organisms of* —. T. Takahashi. *J. Coll. Agric., Imp. Univ.*, 1909, 1, 103–133.

JAPANESE vinegar is made from various raw materials, e.g. soured "saké," soured "moromi" mash of "saké," specially prepared vinegar mash and "saké-kasu," the pressed residue of "saké" mash. In all cases the use of a previously fermented mash is essential to the proper starting of the fermentation. This mash, which is called "tanezu," is prepared by mixing rice "koji," steamed rice, and water. The author has made a detailed study of the micro-organisms contained in it. He has isolated and characterised 7 varieties of bacteria, 2 of wild yeasts, and 2 of *Aspergillus*. The following bacteria are described: (1) *B. ascendans* Henneberg, var. *Tanezu*, which differs from the normal type in its ability to form acid directly from most of the sugars; this variety belongs to Hoyer's class of quick vinegar bacilli. (2) *B. acetosum* Henneberg, var. *Tanezu*, which may be classed among Hoyer's beer-vinegar bacilli and with *B. rancens* Beijerinck. (3) *B.*

acti Brown, var. *Tanezu* I., which forms reducing sugar from mannitol; it also may be classed with *B. rancens*. (4) *B. acti* Brown, var. *Tanezu* II., which resembles the last, but is characterised by the formation of a rose-red colour at high temperatures. (5) *B. acetosum* Henneberg, var. *Tanezu*, also classed with *B. rancens* Beijerinck, but its property of forming reducing sugar from mannitol assimilates it to *B. acti* Brown. (6) *B. acti* Pasteur, var. *Tanezu*, differing from *B. acetigenum* and *B. asenulans* in many respects, and forming acid direct from sugars. (7) *B. xylinoides*, var. *Tanezu*, which differs from the normal type in the fact that its films do not give the cellulose reaction. The amount of acid produced by these bacteria ranges from 1 to 5 per cent., according to the variety. The products of fermentation in media free from alcohol also differ according to the varieties:—some form methyl alcohol and fusel oil; others form isopropyl alcohol, ethyl alcohol, methyl alcohol and fusel oil, and one forms methyl lactate or butyric acid.—J. F. B.

Alcohol; Industrial — and its possibility as a source of power in the Philippines. A. J. Cox. *Philippine J. Sci.*, 1909, 4, A, 232–236.

THE sources of alcohol available in the Philippine Islands are rice, Indian corn, sugar-cane, the sap of the nipa and other palms, and cassava. At present nearly all the alcohol produced is obtained by the systematic "bleeding" of the nipa palm, followed by fermentation and distillation of the "tuba." The wholesale price of 15 litres of 95 per cent. alcohol from this source is 2.40 pesos (5s.), whilst the estimated price for the product from Indian corn is 2.30 pesos (4s. 9½d.), and for that from cassava 2.60 pesos (5s. 5d.) per 15 litres. As gasoline (sp. gr. 0.699) is at present sold in Manila at 2.38 pesos (4s. 11½d.) per 15 litres, and an engine requires about 1.5 times as much 95 per cent. alcohol as gasoline to develop the same power, it follows that alcohol at any price above 1.60 pesos (3s. 4d.) per 15 litres cannot compete with gasoline, except possibly in remote localities.—A. G. L.

PATENTS.

Malt kilns. R. Roth, Erfurt, Germany. Eng. Pat. 5409 Mar. 5, 1909.

In the kiln described, the hot air from the furnace passes through flues, provided with regulating valves, into the kiln proper, which contains a number of horizontal travelling bands placed one above the other. The heated air is then conducted from the top of this part of the kiln through a number of passages into a preliminary drying chamber. The green malt is fed on to a travelling inclined band, reaching to the top of the preliminary drying chamber, and is partially dried by the currents of hot air. It then falls on to the uppermost of the travelling bands in the kiln proper which delivers it to the next band, and so on, the dried malt finally falling from the lowest band into a discharge shoot. An exit flue for the hot air is provided at the bottom of the preliminary drying chamber, and a ventilating dome fitted with a valve is placed at the top of the kiln. In a second form of kiln described, the hot air is conducted from the kiln proper to the under surface of the travelling band in the preliminary drying chamber. In both kilns, the temperature may also be regulated by means of flues in connection with the outer air.—W. P. S.

Vinasses; Process for treating distillery —. F. and E. D. Verbièse. First Addition, dated Jan. 19, 1909, to Fr. Pat. 396,288, Jan. 21, 1908 (this J., 1909, 619).

In the process of clarification referred to in the principal patent, other bases than lime may be used if desired. A large excess of lime should be avoided, since it redissolves some of the precipitated matters and tends to attack the filtering cloths. For this reason it is proposed to remove the greater part of the excess of lime by the passage of a current of carbon dioxide, preferably the gas developed during fermentation.—J. F. B.

XVIII.—FOODS; SANITATION; WATER PURIFICATION, & DISINFECTANTS.

(A.) FOODS.

Preservatives in cream: The use of —, J. M. Hamill. Report to the Local Gov. Board, 1909, Food Report No. 10, 1—35.

ON several occasions traders have represented to the Board that 0.25 per cent. of boric acid (the limit recommended by the Departmental Committee on Preservatives and Colouring Matters in Food, 1901) is an insufficient quantity for the preservation of cream, and that in the conditions under which the cream trade has to be conducted, no limit of boric acid under 0.5 per cent. would suffice. The Board therefore instructed the author to make inquiries and investigations on the subject, and the results are published in this report. A description is given of the sources of the cream supply, methods of separation of cream, distribution of cream, richness of cream, clotted cream, etc. The results are also given of an experimental inquiry into the effect of different amounts of boric acid and boron compounds on the keeping power of cream at relatively high temperatures

Origin.	South America.	Central America.
	Per cent.	Per cent.
Raw.....	1.08—1.35	1.11—1.68
Roasted.....	1.11—1.48	1.15—1.70

and under conditions approximating to those under which the jug-cream trade is carried on. It was found that 0.2 per cent. and 0.3 per cent. of boric acid were insufficient to preserve cream either at 65° F. or 71° F. for more than 3—4 days; 0.4 per cent. and 0.5 per cent. of boric acid prevented the production of acid, but allowed the production of an unpleasant flavour after 4—7 days, and mould growth after about 6 days both at 65° F. and 71° F. A more effective preservative than boric acid is obtained when the boron preservative contains 7 grms. of alkali (Na_2O) per 100 grms. of boric acid. In the presence of this proportion of alkali, 0.4 per cent. of boric acid is practically as effective as 0.5 per cent. at 65° F., but is slightly less effective at 71° F. Cream may be preserved by either of these proportions for about 4—7 days at temperatures up to 71° F.

The following recommendations are made:—

(1). In the interests of the public health and of the consumer, and also with a view to removing difficulties which traders in cream are experiencing on account of present uncertainties, it appears desirable that effect should be given, subject to (2) below, to the recommendations made by the Departmental Committee on Preservatives, 1901, that the only preservative to be used in cream should be boric acid, borax, or mixtures of these boron preservatives; that a maximum limit of boron preservative calculated as boric acid (H_3BO_3) should be prescribed; and that the presence of boron preservatives should in all cases be declared. These provisions should also apply to clotted cream.

(2). An exception might, however, be made in respect of the use of hydrogen peroxide, the addition of which to cream might be permitted, provided that only traces were allowed to remain in the cream.

(3). It appears desirable that the question of issuing regulations on this matter should receive the Board's consideration and that account should be taken of the following points:—

(a). The declaration of the presence of preservative to the purchaser, whether wholesale or retail, should in all cases be adequate, and the preserved cream as an article of commerce should be differentiated from cream which contains no added preservative.

(b). In the case of boracised cream the maximum amount of boron preservative, calculated as boric acid (H_3BO_3), should be 0.4 per cent. from May to October inclusive, and 0.25 per cent. during the remainder of the year.

(c). Cream in which boron preservatives are permitted, subject to the above limits, should in all cases contain at least 40 per cent. of milk fat.

(4). Having regard to the use of sweetening agents such as saccharin to conceal sourness of cream and to impart an unnatural sweetness, it appears desirable that their presence should be notified to the purchaser.

—W. P. S.

Coffee: Amount of caffeine in —, and loss of caffeine on roasting coffee. K. Lendrich and E. Nottbohm. Z. Unters. Nahr. Genussm., 1909, 18, 299—308.

HEFELMANN (this J., 1908, 1218) found the dry substance of raw unwashed coffee to contain from 0.864 to 1.669 per cent. of caffeine, whilst results recorded by other chemists have differed widely from these figures. The amount of caffeine determined by the authors' method (this J., 1909, 379) in 32 samples of raw coffee varied from 1.05 to 2.83 per cent., and in the roasted beans from 1.09 to 2.95 per cent. Both in the case of the raw and the roasted beans the smallest proportion of caffeine was found in Abyssinian Mocha coffee, and the highest in Cazengo coffee. The proportions, arranged according to the origin of the coffee, were as follows:—

	Asia.	Africa.	Australia.
	Per cent.	Per cent.	Per cent.
Raw.....	1.10—1.65	1.05—2.83	1.35
Roasted.....	1.12—1.68	1.09—2.95	1.42

The samples of Cazengo and Encongo coffee, which contained over 2 per cent. of caffeine, were derived from wild plants in Portuguese Africa. The so-called "wild Congo coffee," with which Cazengo coffee can probably be classed, is produced by *Coffea camphora* (Pierre). The highest value for the caffeine content of this coffee recorded by Siedler (2.36) is exceeded by the Cazengo coffee, with 2.83 per cent. These wild kinds of coffee are regarded as of inferior quality in commerce, and are generally used for blending. Experiments are now being made in Java and Surinam on the cultivation of this coffee. The highest proportions of caffeine found in the samples of cultivated coffee were 1.65 and 1.68 per cent. No sample containing less than 1 per cent. was found, and the authors regard 1 per cent. as the probable lowest limit for commercial samples. Although the percentage of caffeine is probably influenced by the climate and methods of cultivation, it is mentioned as noteworthy that Liberian coffee, which contains the highest proportion among the cultivated kinds, still contains the most when cultivated in other parts of the world. Thus from 1.29 to 1.68 per cent. of caffeine was found in Liberian coffee of different origin. The loss of caffeine on roasting the coffee was found to vary from 1.50 to 8.53 per cent. of the total amount of alkaloid present. Contrary to the experience of Balland (J. Pharm. Chim., 1904, 20, 543) the beans were found to contain a higher percentage of caffeine than the seed-pellicles, whilst the hulls contained a still smaller proportion than the pellicles.—C. A. M.

"Tamari-Shoyu" [soy]; Chemical composition of —, K. Yoshimura. J. Coll. Agric., Imp. Univ., Tokyo, 1909, 1, 89—96.

"TAMARI-SHOYU" is manufactured entirely from soy beans, whereas ordinary "shoyu" is made from equal parts of soy beans and wheat (see this J., 1907, 1062). The mash is made up with soy beans, salt and water

and the "tamari" pressed out after about 20 months. In the following table, the composition of "tamari" is shown comparatively with that of ordinary "shoyu":—

	"Tamari."	"Shoyu."
Specific gravity	1.205	1.197
Water, per cent. by weight	45.68	67.15
Dry substance, per cent. by weight ..	54.32	32.85
Total nitrogen, per cent. by weight ..	2.385	1.240
Protein nitrogen, per cent. by weight ..	0.536	0.037
Ammonia nitrogen, per cent. by weight ..	0.305	0.140
Basic nitrogen, per cent. by weight ..	0.379	0.330
Nitrogen in other forms, per cent. by weight ..	1.165	0.742
The dry substance contains:—		
Organic matter, per cent.	58.04	49.12
Ash, per cent.	41.96	50.88
Sodium chloride, per cent.	16.64	44.94

The destruction of the proteins during the ripening period is not so intense in the case of "tamari" as in that of ordinary "shoyu." The authors have examined the bases of "tamari" more particularly. From 1 litre of "tamari," they isolated 0.3 gm. of putrescine, 0.7 gm. of ornitine, 0.7 gm. of a base, $C_6H_9N_3$, and 4.5 grms. of ammonia. The putrescine is regarded as being derived from the further breaking down of the ornitine, and both these bases are probably formed at the cost of arginine. The base, $C_6H_9N_3$, is probably a putrefaction derivative of histidine. It is known that glycine, the protein of the soy bean, yields arginine, lysine, and histidine on hydrolysis, but none of these bodies were found to have survived in the "tamari."—J. F. B.

"Shoyu" [soy]; *The carbohydrates of* — R. Mitsuda. J. Coll. Agric., Imp. Univ., Tokyo, 1909, 1, 97—101. (See preceding abstract.)

THE sugars present in "shoyu" have been isolated in the form of their osazones. After removing the greater part of the salt from the "shoyu" by evaporation, the liquid was decolorised with animal charcoal and treated directly for the preparation of the osazones. On purification, there were obtained from 400 c.c. of "shoyu," 5 grms. of glucosazone and 0.6 gm. of galactosazone, whilst maltosazone was recognised microscopically, but not isolated. When "shoyu" or "tamari" is exactly neutralised and distilled, traces of furfural are obtained, and this body must be regarded as pre-existent in the "shoyu." The quantities of furfural found did not exceed 0.0002 per cent., and the proportion appeared to be in some relation to the acidity of the "shoyu." When the "shoyu" is distilled without neutralisation, the proportion of furfural obtained is somewhat higher. It would appear that the presence of furfural in "shoyu" is due to the action of the organic acids on the pentosans at the ordinary temperature during the period of ripening. The author has studied the pentosan content of the "moromi" at different stages during the ripening process. The percentage of pentosans in the pressed extract increases in the early stages up to a maximum after 5 months; it subsequently decreases owing to the action of micro-organisms or to that of the organic acids. Compared with the amount of pentosans in the raw material, the quantity which is extracted by the salt water during the ripening process is quite small.—J. F. B.

Determining phosphoric acid in organic substances. Schaumann. See XXIII., Org. Quant.

Pure Food Act (1908), New South Wales. Further Regulations. (See this J., 1909, 902 and 999.) Bd. of Tr. J., Sept. 23, 1909. [T.R.]

A "SUPPLEMENT to the Government Gazette of New South Wales" for 28th July, 1909, contains further regulations which have been made under the Act.

These additional regulations relate to drugs, milk, butter, cheese, margarine, and condensed milk, and provide that certain packages of food shall be exempt from the

provisions of Section 14 of the "Pure Food Act" which relates to labelling, and requires that a statement as to the weight, number, measure or volume of the contents shall be attached to packages of food.

The regulations operate partly from the 28th July, 1909, and partly from 1st January, 1910.

PATENTS.

Flour from wheat; Art of milling and conditioning — H. Simon, Ltd., Manchester. From L. M. Thomas, Wilhelmshafen, Germany. Eng. Pat. 9946, May 7, 1908.

THE flour is subjected to the action of a current of air saturated with water vapour and having a temperature of from 30° to 50° C. The flour is led through the mixing apparatus at such a rate that it absorbs at least 0.1 per cent. of its weight of water.—W. P. S.

Flour; Treatment of — [improving its bread-making properties]. A. E. Humphries, Weybridge, Surrey. Eng. Pats. 13,135, June 19, 1908, and 17,279, Aug. 17, 1908.

THE flour is sprayed, preferably during the intermediate stages of the milling process, with water or with solutions of various substances. A preliminary experiment is necessary in order to determine the character of the solution required to be used. For instance, the weight of the flour may be increased by from 1 to 2 per cent. by simply using a water spray. For increasing the gas-making qualities of the flour, a solution containing 13 per cent. of maltose, 8 per cent. of dextrin, and 5 per cent. of malt extract (300° Lintner) may be employed; the solution may also contain a small quantity of ammonium phosphate. To improve the dough, the spray may contain calcium, magnesium, or potassium phosphates; and to restrain fermentation, etc., a solution containing 3 per cent. of potassium hydroxide, or a saturated solution of common salt may be sprayed on to the flour. The amount of spray used should be such that the flour receives from 0.2 to 0.5 per cent. of its weight of salt or salts, except in the case of the alkali spray, when the quantity of alkali added to the flour should not exceed 0.05 per cent.—W.P.S.

Flour; Process for improving [the baking qualities of] — F. Tildesley, A. B. Ritchie, and E. J. Watkins, London. Eng. Pats. 3612, Feb. 13, 1909, and 6178, Mar. 15, 1909.

THE flour is treated in an agitator with air containing sulphur trioxide, sulphur trioxide and chlorine, or with air which has been passed through or over Nordhausen sulphuric acid and one or other of the following acids:—Hydrochloric acid, hydrofluoric acid, hydrobromic acid, hydriodic acid, nitric acid, or nitrous acid.—W. P. S.

Baking-powder. J. H. Kellogg, Battle Creek, Mich. U.S. Pat. 932,138, Aug. 24, 1909.

THE baking powder is prepared by impregnating gluten with hydrochloric acid, drying the same, and mixing it with suitable quantities of flour, or starch, and sodium bicarbonate.—W. P. S.

Milk; Process for the manufacture of dried — Swiss Dry Milk Co. Fr. Pat. 398,941, Dec. 23, 1908. Under Int. Conv., April 27, 1908.

THE milk is concentrated under reduced pressure at a temperature of about 40° C. until the greater part of the water has been evaporated. It is then dried completely on a rotating drum heated to a temperature above 100° C.—W. P. S.

Condensation of liquid [milk] in vacuo; Continuous — Swiss Dry Milk Co. Fr. Pat. 400,513, March 8, 1909.

THE liquid, e.g., milk, is fed into the apparatus through the pipe, A, and is distributed from the vessel, B, through the ring of holes, C, on to the exterior surface of the spiral, D. The latter is supported on the exterior surface of the cylinder, b, so as to form a spiral channel, e, through which the heating medium is circulated, entering through the pipe, G, and being discharged through the pipe, H.

The milk flows over the outer surface of the spiral, is condensed or concentrated by the heat and is discharged from the bottom of the outer containing vessel, *a*, through the pipe, *E*; holes, *f*, *f*, being cut in the lower end of the cylinder, *b*, to allow the passage of the condensed milk to the outlet. The vessel, *a*, is connected by the pipe, *F*, to a vacuum pump, by which it is exhausted.—W. H. C.

Milk and other liquid foods, medicines, serums, etc.; Sterilisation of — V. Henri, A. Helbronner, and M. von Recklinghausen. Fr. Pat. 400,602, Mar. 2, 1909.

The liquid to be sterilised is allowed to flow into a funnel-shaped vessel, having corrugated sides, and inclined at an angle to the vertical. This vessel is rotated and the liquid flows, in a thin layer, down the sides to the bottom or stem, from which it is discharged into a receiving chamber. While the liquid is flowing down the sides of the vessel, it is subjected to the action of ultra-violet rays proceeding from a mercury vapour lamp fitted at the top of the vessel. A current of sterilised air or inert gas is passed upwards through the vessel while the operation is proceeding, in order to prevent the liquid from becoming heated.—W. P. S.

Sterilising liquids [foods], etc.; Process and means for — by the action of ultra-violet rays. Soc. Le Ferment. Fr. Pat. 400,760, Mar. 13, 1909.

The liquid is placed in a closed vessel, such as a bottle or other receptacle, and is subjected to the action of ultra-violet rays. The stopper of the bottle, or the bottle itself, is made of quartz, silica, or other substance which offers no obstacle to the passage of the rays, and the latter may be allowed to pass through the stopper, sides, or bottom of the bottle. A number of bottles may be placed on revolving plates situated around a central source of the light, and reflectors may be provided for concentrating the rays.—W. P. S.

Vegetable albumin and animal casein; Process of treating — and the product thereof. F. G. Wiechmann, New York, Assignor to Protal Co. U.S. Pat. 932,527, Aug. 31, 1909.

SEE Fr. Pat. 388,492 of 1908; this J., 1908, 909.—T. F. B.

Cooling apparatus for fluid or semi-fluid substances [margarine emulsions]. Eng. Pat. 1160. See XII.

(B.)—SANITATION; WATER PURIFICATION.

PATENTS.

Trade effluent [from wool washing, etc.]; Method and apparatus for purifying — T. Waite, Bradford, Yorks. Eng. Pat. 17,644, Aug. 22, 1908.

THE effluent is pumped into one or more "seak" tanks where the grease is separated by the addition of sulphuric acid. These tanks are provided with a trumpet-shaped agitator through which air is injected by means of a steam jet. The acid water is run off on to a water-wheel which operates a stirrer in a separate tank; in this tank is a bucket-wheel which delivers automatically a certain proportion of lime solution into the acid water. This then flows into neutralising tanks where a second precipitation takes place; the tank fills up and then the liquid is run off through a siphon into another similar tank where a further clarification is effected. The clarified liquid next passes to another water-wheel which automatically revolves a circular sprinkler situated over a filter bed composed of ashes suitably graded, through which the purified effluent is discharged. (Reference is directed to Eng. Pat. 11,366 of 1901; this J., 1902, 1292.)—J. F. B.

Water purifying and softening plant. H. Boyd, Timperley, Cheshire. Eng. Pat. 17,672, Aug. 22, 1908.

THE apparatus consists of a series of filtering tanks of circular section, each containing a filter which can be readily lifted out for cleaning, any mud or sediment being removed through a cock at the bottom. In combination with these filters there is an arrangement of bucket-wheels for measuring the water to be treated and the chemicals required. The water to be treated is delivered into a series of buckets mounted on a vertical chain, and thus provides the motive power for the measuring of the reagent and the agitation of the chemicals. The reagent and measured water fall together into a spout which conducts them to a mixing tank from which the filters are fed. The filters are connected in series, the top of one to the bottom of the next, the water passing upwards through the filters. The filter-beds are held in conical seatings making a tight joint with the walls of the circular tanks.—J. F. B.

Water; Process for purifying — W. P. Morgan. Fr. Pat. 400,525, Mar. 9, 1909.

THE process relates to the purification of waters containing calcium salts. To every 4.5 litres of the water is added a mixture consisting of aluminium sulphate, 0.256 gm.; kaolin, 0.384 gm.; and starch, 0.640 gm. These reagents may be conveniently made up in the form of tablets; when required for use, a tablet is ground up with a little water and the paste added to the bulk of the water. The coagulum which forms entrains the bacteria, suspended matters, and dissolved organic substances present in the water, and, after the lapse of five minutes, the precipitate is removed by filtering the water through fibrous material. (See also U.S. Pat. 914,887 of 1909; this J., 1909, 438.)—W. P. S.

Effluents; Process for the purification of — by means of finely ground humic coals (e.g., lignites, peat). W. Rothe and Co. Ger. Pat. 212,740, June 10, 1908.

THE effluent is treated with a mixture of humic coal (lignite, peat) and ordinary pit coal, both in a finely-divided condition, together with a salt of a heavy metal. The pit coal does not exert any purifying action, but accelerates the settling of the sludge, and renders the latter better suited for subsequent utilisation as fuel or by carbonisation.—A. S.

(C.)—DISINFECTANTS.

PATENT.

Disinfectants; Manufacture of — H. Schneider. Berlin. Eng. Pat. 2472, Feb. 2, 1909. Under Int. Conv., May 11, 1908. Addition to Eng. Pat. 3789 of 1907, dated Feb. 16, 1906.

SEE Addition of Feb. 3, 1909, to Fr. Pat. 377,141 of 1907; this J., 1909, 1000.—T. F. B.

XIX.—PAPER, PASTEBOARD, &c.

Cellulose esters; Notes on — R. G. Woodbridge. J. Amer. Chem. Soc., 1909, 31, 1067—1071.

THE results of some work on the propionates and formates of cellulose are given. Cellulose tripropionate may be prepared by the action of propionic anhydride upon cellulose in the presence of sulphuric acid or zinc chloride, the latter causing more complete esterification to take place in a shorter time. The properties of cellulose tripropionate are essentially the same as those of the acetate. It may be distinguished from the latter by its solubility in ethyl acetate. On spontaneous evaporation, solutions of the tripropionate yield good films, which are, however, not superior to those which can be obtained from the acetate. Cellulose formate is formed by the action of anhydrous formic acid upon cellulose in the presence of sulphuric acid. It is soluble in formic acid and zinc chloride solution, but insoluble in methyl, ethyl and amyl alcohols, acetone, chloroform, acetylene tetrachloride, ethyl acetate, amyl acetate, aniline, and nitrobenzene. It was not found possible to prepare a fibrous cellulose formate.—W. P. S.

Celluloid; Flameless decomposition of — A. Panzer. Z. angew. Chem., 1909, 22, 1831—1837.

CELLULOID was heated by an electrically heated wire touching its surface, in a vessel from which the air had been removed, till decomposition set in. The current was then switched off, the decomposition allowed to continue, and the products were examined. It was found that 24.8 per cent. of the weight of the celluloid was obtained as gaseous products, and 16.8 per cent. remained behind as charcoal or coke; the remaining 58.4 per cent. of liquid and solid products of distillation could be only partially collected, owing to the difficulty of condensing them. The charcoal was found to be, or to become when very gently heated, pyrophoric. The fires which have from time to time arisen in celluloid factories have very probably been caused by decomposition of the celluloid, followed by ignition of this pyrophoric charcoal. The gases consisted of (by volume) nitric oxide, 51.1; nitrous oxide, 5.5; carbon dioxide, 6.8; carbon monoxide, 30.9; hydrogen, 0.9; nitrogen, 4.8 per cent. The liquid products consisted very largely of camphor and nitric acid, very probably the whole of the camphor contained in the celluloid passing over as Kachler's camphor nitrate, $2C_{10}H_{16}O.N_2O_5$. Possibly the explosions which have occurred during celluloid factory fires are caused by this substance or the products of its decomposition by heat. Further investigation is, however, necessary. (See also this J., 1909, 1001.)—J. T. D.

PATENTS.

Paper, cardboard, etc.; Method of glazing — Armitage and Ibbetson Ltd., W. H. and F. Ibbetson, R. F. Woodburn and E. Norrie, Bradford, Yorks. Eng. Pat. 3883, Feb. 17, 1909.

PAPER or cardboard is coated with a film of gelatin by applying the gelatin or other glazing material in a fluid state to the surface of the paper, and passing the latter between a pair of rollers revolving in close proximity to each other but not actually in contact. One of the rollers supports the paper, whilst the other applies the fluid glaze, which is fed on to it by another roller revolving in a trough. The film is subsequently polished by pressing it in contact with a sheet of glass by means of resilient rollers.—J. F. B.

Papers for decorative purposes; Manufacture of varnished — C. Follot. Fr. Pat. 400,692, March 11, 1909.

PAPER is first coated with a "finish" or size and is then given a coating of coloured lacquer. The varnished paper is subsequently embossed by means of engraved rollers which impress striations or dots on its surface in such a way that various reflections of the light are produced according to the position in which the paper is held. Designs may be embossed or reserved on the paper in addition to the general groundwork of the decoration; also different colours may be printed in design by means of the relief portions of the embossing rolls.

—J. F. B.

Plastic material [from celluloid] for manufacture of combs and moulded articles. L. Desvaux and H. Allaire. Second Addition, dated March 6, 1909, to Fr. Pat. 388,097, March 11, 1908 (this J., 1908, 873, 1982).

ACCORDING to this addition the whole or a portion of the "maisin" claimed in previous specifications for incorporation with celluloid may be replaced by vegetable proteins of the amidine group, e.g., gliadin, gluten-fibrin, mucedin, zein, guaneide, etc., which are soluble in alcohol. For instance a celluloid mixture containing 50 parts of nitrocellulose and 25 parts of camphor may be milled with 50 parts of an amidine previously moistened with alcohol.—J. F. B.

Bamboo pulp and analogous materials; Treatment of — J. S. Turner and A. W. Maxwell. Fr. Pat. 401,035, March 19, 1909. Under Int. Conv., March 20, 1908.

SEE Eng. Pat. 6277 of 1908; this J., 1909, 851.—T. F. B.

Cellulose acetate; Process for producing solutions of — Fürst Guido Donnersmarck'sche Kunstseiden und Acetatwerke. Fr. Pat. 400,652, March 10, 1909.

SEE U.S. Pat. 922,340 of 1909; this J., 1909, 671.—T. F. B.

Treating waste sulphite liquor, and new product [tanning material] therefrom. Eng. Pat. 17,956. See XIV.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENTIAL OILS, & EXTRACTS.

Saponin-digitalin group of glucosides; A new member of the — B. Moore, F. W. Baker-Young, and S. C. M. Sowton. Pharm. J., 1909, 80, 364.

THE residue left after expressing the oil from the seeds of *Bassia longifolia* (mowrah seeds), has, in common with digitalis, an irritating action when in contact with a cut surface of the skin. A quantity of the residue was extracted with alcohol, and precipitated with ether. The substance on purifying proved to be a glucoside (carbon 51.9, hydrogen 6.85 per cent.), for it yielded a hexose and "mowrie acid" on hydrolysis. It has a strong coagulating effect on blood corpuscles in saline suspension. "Mowrin," the glucoside, has a stronger effect in this way than the salts of mowrie acid. Both substances are poisonous, and have an effect on the heart resembling that of digitalis.—F. SHDN.

Bismuth iodide; Hydrolytic dissociation of — R. Dubrisay. Comptes rend., 1909, 149, 451—453.

THE hydrolysis of bismuth iodide results in the formation of two distinct compounds; in low concentrations, when the amount does not exceed 0.002 gram-atom of bismuth per litre, a red compound corresponding to the formula, $BiOI$, is formed. Stronger concentrations result in the formation of a black compound having the composition $Bi_2O_3.5HI$. As a continuous curve is obtained when the contents of bismuth and hydriodic acid are represented graphically, it is concluded that two oxy-iodides exist. It is further shown that the dissociation of bismuth iodide increases as the temperature is raised.—W. P. S.

Iodate in commercial potassium iodide. Andrews. See VII.

Chemicals for use in factories: Duty-free admission of certain —. Dutch Bd. of Tr. J., Sept. 23, 1909. [T.R.]

A Dutch Royal Decree, dated the 31st July, 11th August, and 16th August, provides for the duty-free admission, under the conditions prescribed by the Royal Decree of the 11th August, 1908, of the following articles:—

(a) Fat mixed with pyroigneous spirit, for use in chrome-leather tanneries, and "cellangoh" (a solution of nitro-cellulose and camphor in alcohol and ether), for use in shoe factories;

(b) Chloride of ethyl, for use in scent manufactories; and

(c) Acetate of amyl, for use in electric incandescent lamp factories.

PATENTS.

Serum or anti-toxin [swine fever]: New — and method of obtaining same. Pharm. Inst. L. W. Gans, Frankfurt-on-Maine, Germany. Eng. Pat. 5773, March 10, 1909. Under Int. Conv., March 11, 1908.

A PROTECTIVE medium against hog cholera or swine fever is prepared by pressing or extracting the organs of the thoracic and abdominal cavities or the muscles of animals infected with the disease, after the animal has been bled. The virus in the extract is then killed by the addition of suitable germicidal agents, e.g., chloroform or toluene. The inoculating medium thus obtained is injected into animals of a different species, their blood being then prepared as a serum in the usual way.—J. F. B.

Blood: Process for obtaining a therapeutic agent from animal —. S. Bergel. Ger. Pats. 205,025, July 27, 1907, and 212,112 and 212,113, July 24, 1908.

FRESH animal blood obtained under aseptic conditions, from immunised animals, is centrifuged till the red corpuscles have separated completely from the white corpuscles and blood plasma. After removing the red corpuscles, the remaining portion of the blood is coagulated, and the mixture of fibrin with serum and white corpuscles is dried and pulverised at temperatures below 40° C., in some cases after addition of other substances such as yeast powder, collargol (colloidal silver), nucleic acid, silver citrate, zinc perhydrol (zinc peroxide), etc. After drying and pulverising, the product may be sterilised by heating, without destroying its therapeutic properties. After separation of the red corpuscles and coagulation of the residue, the fibrin may be separated from the mixture of blood serum and white corpuscles and the two products worked up separately according to the process described.—A. S.

Prophylactic substance in the tissues of immunised animals: Process for recovering the —. L. Heim. Ger. Pat. 212,709, March 20, 1908.

HITHERTO it has been thought that the prophylactic substances produced in immunised animals are contained in remunerative quantity, only in the serum, but according to the present patent, very active preparations can be obtained from the tissues of the animals. The muscles and interior organs of the animals are dried at a low temperature or by means of a mixture of acetone and ether, then freed from fat by means of acetone, and after removing the solvent, ground to a fine powder and the latter triturated with about ten times its quantity of water. The mixture is subjected to the action of proteolytic enzymes in an incubator nearly to the point at which the solution no longer gives the biuret reaction. It is then filtered and concentrated at a low temperature. The muscles and organs may also be mixed with sand and kieselsol, pressed, and the residue and press-juice treated separately according to the process described above.—A. S.

Vanilla: Oleo-resin of —. E. J. Sheehan, Assignor to San Gabriel Valley Fruit Products Co., New York. U.S. Pat. 931,805, Aug. 24, 1909.

THE product described is an oleo-resinous extract from vanilla beans; it is brownish-amber in colour, has a

gummy consistence, and contains approximately 10 per cent. of vanillin, 41 per cent. of neutral resins of the consistence of soft paraffin, insoluble in aqueous alkali but soluble in ether, and 31 per cent. of organic acids and acid resins; the latter are amber yellow in colour, of pasty consistence, are soluble in aqueous alkali and in alcohol, and on sublimation yield fine white crystals melting at about 73.5° C.—W. P. S.

Phenyl acetate: Antiseptic composition containing —. N. Sulzberger, New York. U.S. Pat. 932,647, Aug. 31, 1909.

A NON-IRRITANT, analgesic and antiseptic preparation for pharmaceutical use is claimed, containing phenyl acetate in admixture with about 3 per cent. of eucalyptus oil and 1 per cent. of peppermint oil. Generally expressed, the invention claims the use of a solution of about 5 per cent. of essential oils in the acetic ester of a phenol.—J. F. B.

Silver and albumose: Preparation of basic compounds of —. Chem. Fabr. auf Actien, vorm. E. Schering. Fr. Pat. 400,627, March 8, 1909. Under Int. Conv., March 23, 1908.

SOLUTIONS of albumose are mixed with solutions of the double compounds of salts of silver with non-irritant and non-poisonous organic bases, and the mixtures are dried, or the complex compounds precipitated by appropriate means. Compounds of albumose with silver nitrate, carbonate, and phosphate in combination with ethylenediamine and piperazine are described.—J. F. B.

Quinine: Manufacture of a sulphur compound of —. Valentiner und Schwarz. Fr. Pat. 400,631, March 9, 1909.

A COMPOUND having a composition corresponding to the formula, $C_{20}H_{23}N_2OS$, is prepared by heating anhydrous quinine with about 20 per cent. of sulphur at a temperature below the melting point of the base. The mixture begins to fuse at a temperature of 120° C., and after half an hour at 145° C., the reaction is complete. The product is dissolved in dilute hydrochloric acid and purified by precipitation from the filtered solution by the addition of ammonia.—J. F. B.

Emulsions of essences or volatile oils: Process for obtaining — immediately by mixture with water. M. Saporta. Fr. Pat. 400,911, March 17, 1909.

ESSENTIAL oils are mixed with a concentrated solution of "pure black soap" in alcohol; they are then stated to be readily emulsified in water. The following example is given of such an emulsifiable mixture: Soap, two parts, 90 per cent. alcohol, one part, aniseed oil, two parts, peppermint oil, two parts.—T. F. B.

Bacteria: Process for obtaining non-toxic, therapeutic preparations from acid-resisting —. Kalle und Co., Akt.-Ges. Ger. Pat. 212,350, May 17, 1908.

ACID-RESISTING bacteria are extracted for a prolonged period with an aqueous emulsion of lecithin, preferably in presence of a small quantity of hydrogen peroxide, and the liquid separated from the insoluble matter. The preparation obtained from tubercle-bacilli is stated to be of value in the treatment of tuberculosis.—A. S.

Protein substances from pathogenic bacilli: Process for obtaining active —. Kalle und Co. Ger. Pats. 212,830, May 17, 1908, and 212,831, July 14, 1908.

(1). THE bacilli are freed from fat, preferably by a method in which the protein is not coagulated, and are then heated with a solution of a primary or secondary alkylamine, or of a substance (dimethylurea, dimethylbenzamide, etc.) capable of yielding the same, until the greater part of the organic matter has dissolved. The solution is filtered and treated with acetic acid, whereupon a precipitate is obtained consisting of a protein substance, which, whilst relatively non-toxic, possesses great therapeutic value. The process is specially applicable to tubercle bacilli.

(2.) If anthrax bacilli which have first been subjected to the action of nitrous acid, be treated according to the process described, a very active preparation of anthrax toxin is obtained.—A. S.

Organic arsinic acids and their salts; Process for preparing [solutions of] — insoluble in water. P. Wolff. Ger. Pat. 213,394, May 6, 1908.

ORGANIC arsinic acids and their salts which are insoluble in water, are readily dissolved in glycerin, in which form they can be administered internally, either undiluted or diluted with water. A solution of mercuric *p*-aminophenylarsinate in glycerin has a stronger action on trypanosomes than the sodium salt (atoxyl).—T. F. B.

Hydroxyarylarsonoxides; Process for preparing —. Farbwerke vorm. Meister, Lucius, und Brüning. Ger. Pat. 213,594, Feb. 5, 1908.

By treating hydroxyarylarsonic acids with weak reducing agents, such as sulphurous acid, hydriodic acid, phenylhydrazine, phosphorus trichloride, or thionyl chloride, the arsinic acid group is reduced to the AsO group. For example, 114 grms. of sodium *p*-aminophenylarsinate are dissolved in 1.6 litres of water, and treated with 20 grms. of potassium iodide and 520 c.c. of dilute sulphuric acid (1 : 5); the solution is saturated with sulphur dioxide at about 18° C., then saturated with salt, and extracted with ether. The extract is freed from acid and the ether distilled off from the phenol-*p*-arsenoxide. If this is warmed with a hydrosulphite in neutral solution, *p*-arsenophenol, $\text{HO.C}_6\text{H}_4.\text{As} : \text{As.C}_6\text{H}_4.\text{OH}$, is produced.—T. F. B.

Trichloroacetylsalicylic acid; Process for preparing —. Chem. Fabr. von Heyden A.-G. Ger. Pat. 213,591, Jan. 16, 1908.

TRICHLOROACETYL SALICYLIC acid is obtained in the form of tasteless, white crystals, melting at 150–152° C., by the action of trichloroacetyl chloride or trichloroacetic anhydride, or a mixture of trichloroacetic acid and phosphorus pentoxide or trichloride, on salicylic acid or its salts, alone, or in presence of condensing agents, such as tertiary bases.—T. F. B.

Aromatic halogenalkyloxy-monocarboxylic acids; Process for preparing —. Chem. Fabr. von Heyden A.-G. Ger. Pat. 213,593, Jan. 22, 1908.

HALOGENALKYLEETHERS of cresols, of the general formula, $\text{CH}_3.\text{C}_6\text{H}_4.\text{ORX}$, where R is an alkyl radical and X a halogen, are oxidised to the corresponding carboxylic acids, without the alkyloxy-group being attacked, by such oxidising agents as convert toluene to benzoic acid (e.g., permanganate, bichromate and sulphuric acid, etc.).—T. F. B.

Camphor; Process for making — in a form easily handled and readily compressed. Chem. Fabr. auf Actien. vorm. E. Schering. Fr. Pat. 398,881, Jan. 27, 1909. Under Int. Conv., Feb. 6, 1908.

SEE Eng. Pat. 1532 of 1909; this J., 1909, 814.—T. F. B.

Aldehydes and ketones [with unsaturated fatty acids]; Process for making compounds of —. Farbwerke vorm. Meister, Lucius, und Brüning. Fr. Pat. 400,738, June 18, 1908.

SEE Eng. Pat. 13,790 of 1908; this J., 1909, 519.—T. F. B.

Lecithin; Process for extracting — from the seeds of lupins and other podded plants. H. C. Buer. Fr. Pat. 400,878, March 16, 1909.

SEE Ger. Pat. 210,013 of 1908; this J., 1909, 675.—T. F. B.

Sterilisation of milk, medicines, etc. Fr. Pat. 400,602. See XVIII.1.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

PATENTS.

Images on glass, ceramic, metallic, or other surfaces; Reproduction of —. A. R. Ling, T. Rendle, and E. W. Colbrook. London. Eng. Pat. 17,432, Aug. 19, 1908.

IMAGES which will withstand washing are obtained on ground glass or similar rough surface, by means of a sensitising solution containing invert sugar, honey, or other carbohydrate, a bichromate, and a volatile solvent for the bichromate and carbohydrate. The use of nitrocellulose in the sensitising solution (Eng. Pat. 24,214 of 1907; this J., 1908, 592) is unnecessary with rough surfaces. Suitable solvents are ethyl alcohol, wood spirit, acetone, ether, and ethyl acetate. Glycerin may be used in place of a carbohydrate, in which case acetic acid is used as solvent, and chromic acid as sensitiser. Bichromates of lithium, potassium, ammonium, strontium, calcium, copper, or iron may be used, as also may polychromates. The following is an example of such a sensitising solution:—Lithium bichromate, 2 grms.; honey, invert sugar, or other carbohydrate, 4 grms.; ethyl alcohol or wood spirit, 100 c.c.—T. F. B.

Images on glass, ceramic, metallic, or other surfaces; Reproduction of —. A. R. Ling, T. Rendle, and E. W. Colbrook. London. Eng. Pat. 17,433, Aug. 19, 1908.

IN the process described in Eng. Pat. 24,214 of 1907 (this J., 1908, 592), it is necessary to use a certain amount of water to dissolve the bichromate. It is found that more even films can be obtained by omitting the water, and using a volatile solvent or solvents for the bichromate and the carbohydrate which are miscible with the nitrocellulose solution. Thus, the sensitising solution consists of a bichromate of lithium, calcium, strontium, ammonium, sodium, potassium, copper, or iron, with a carbohydrate or glycerin, a solvent, which may consist of a mixture of ethyl alcohol or wood spirit with ether or ethyl acetate, and a nitrocellulose soluble in the solvent used. The bichromates may be replaced by polychromates or chromic acid; in the latter case, a difficultly oxidisable hygroscopic substance, such as glycerin, is used in place of a carbohydrate. Six examples of sensitising solutions are given.—T. F. B.

Photo-engraving; Preparation of surfaces suitable for —. A. Payne, Whitley Bay. Eng. Pat. 18,775, Sept. 7, 1908. Addition to Eng. Pat. 28,415 of 1907, dated June 22, 1908. (See this J., 1909, 383.)

A COATING of metal is deposited, electrolytically or otherwise, on a prepared plate bearing a "substratum resist," the latter is removed, and the plate is etched by means of a solution which does not affect the metallic coating. Thus, a prepared zinc plate may receive a coating of copper and then be etched by means of dilute nitric acid, or a brass or copper plate may be coated with silver and treated with ferric chloride. The plate prepared with a resist may be first etched and then metal may be deposited subsequently.—T. F. B.

Printing plates and the like; Process for producing —. E. Albert, Munich. Eng. Pat. 25,934, Dec. 1, 1908. Under Int. Conv., Dec. 6, 1907.

A SUITABLE plate, coated first with a resinous substance and then with a film of bichromated gelatin, is exposed under a negative, developed by means of water, and then treated with alcohol thickened by means of tannin or glycerin, or both, which rapidly removes the uncovered portions of the resinous layer. When this solvent action is finished, the plate is immediately washed in water, and finally etched.—T. F. B.

Three-colour screens for photography and process for their manufacture. J. Bamber, London. Eng. Pat. 11,147, May 14, 1909. Addition to Eng. Pat. 3252, Feb. 13, 1908 (see this J., 1908, 1132).

IN order to obviate the necessity of using a light filter for colour photography, the "tacky" substance used to hold the coloured gelatin grains to their support, is suitably coloured to regulate the light passing through it; the grains of gelatin are pressed on to the support, which is coated with the coloured "tacky" substance, so that the latter is partly forced up between the grains, forming a filter for the white rays, whilst that remaining beneath the grains modifies the action of the blue rays passing through the grains. —T. F. B.

Photography of colours by means of a screen and a special support; Process for the —, and its application to phototypic and other processes. E. C. G. Galle. First Addition, dated May 29, 1908, to Fr. Pat. 389,977, July 16, 1907.

INSTEAD of preparing the three-colour screen by superposition, as in the original patent (see Eng. Pat. 15,050 of 1908; this J., 1909, 914), it is prepared by photographing with a Lumière autochrome plate a surface coloured in three sets of areas with violet, orange, and green, or with red, blue, and yellow. —T. F. B.

Cinematograph film; Non-inflammable — and its manufacture. G. Chandon de Briailles. First Addition, dated March 30, 1908, to Fr. Pat. 386,845, April 20, 1907.

THE films described in the principal patent (this J., 1908, 834) may be prepared by means of an apparatus consisting of a cylinder rotating in a vat which contains the gelatin, kept in a liquid condition by a water-bath or similar device. The surface of the cylinder is polished and made of material not affected by gelatin. The gelatin adheres to the cylinder, forming a continuous band, which, when dry, is coated with nitrocellulose and cut by means of a knife supported on a carriage which travels on an endless thread along the surface; suitable gearing regulates the width of the band cut. If the film is to be printed mechanically, its surface is made porous by adding glycerin or other similar substance to the composition; the printing ink may also contain a dyestuff soluble in boiling oil, and also a base which can combine with the chlorine in the chondrine, forming a mordant. —T. F. B.

Cinematograph films; Process of restoring worn —. Soc. Anon. des Plaques et Papiers Photographiques A. Lumière et ses fils. Fr. Pat. 400,739, June 19, 1908.

CINEMATOGRAPH films which have, from continued use, become dull or scratched, are rendered fit for use again by re-polishing them, for instance, by applying a coating of collodion or celluloid to each side of the film by the aid of a suitable solvent and gentle pressure of a roller. —T. F. B.

Photographic film; Non-inflammable —. Soc. Anon. des Plaques et Papiers Photographiques A. Lumière et ses fils. Fr. Pat. 401,228, July 11, 1908.

NON-INFLAMMABLE photographic films are prepared by applying to a polished surface a thin layer of cellulose acetate or other non-inflammable cellulose ester, then a layer of gelatin, and finally a photographic emulsion. The cellulose acetate layer need not be more than one-fifth to one-half the thickness of the entire film. The gelatin may have been treated with formaldehyde, alum, etc. Films prepared in this manner are said to be unaffected in dimensions by the subsequent treatment. —T. F. B.

Photographs on metal, porcelain, glass, or other non-porous substances; Process for obtaining — by the gelatin-chromate process. A. Hans. Fr. Pat. 401,370, March 29, 1909.

SEE Ger. Pat. 212,761 of 1908; this J., 1909, 1066. —T. F. B.

Cellulose compounds in definite shapes [threads, films, &c.] Eng. Pat. 11,625. See V.

XXII. — EXPLOSIVES, MATCHES, &c.

Powder; Determination of nitrogen in gelatinised —. O. Poppenberg and E. Stephan. Z. ges. Schiess- und Sprengstoffw., 1909, 4, 350–351.

THE Schultze-Tiemann method (ferrous chloride and hydrochloric acid) for the determination of nitrogen is not applicable to powders containing nitroglycerin owing to the volatility of this body. The drawbacks of the nitrometer method are, that it takes a very long time to dissolve the gelatinised powder, and that carbon monoxide and carbon dioxide may possibly be produced by the prolonged action of the mixed acids on the cellulose and thus vitiate the results. Further, such substances as are added, either as stabilisers or to reduce muzzle flash, may react with the nitrosyl sulphuric acid to produce oximes and thus give low results. The authors, in order to determine the true nitrogen-content of gelatinised powder, make use of a bomb having gas outlets both at the top and bottom (see figure). One gram. of the explosive is mixed with 1.0–1.5 grms. of copper oxide, and the mixture is placed in a cylindrical iron cup having a stout copper wire projecting from the bottom into the interior. This copper wire serves, when the cup is introduced into the bomb, as the lower terminal for the current, and is connected with the upper insulated terminal by a thin platinum wire, 0.1–0.15 mm. diameter. The mixture surrounds this platinum wire, which is burnt through on the passage of the current. Very small charge densities can be employed, and the authors, working with as low a charging density as 0.06, found no appreciable amounts either of oxides of nitrogen or of ammonia in the products of decomposition. The firing takes place in an atmosphere of carbon dioxide, the gases are swept, by a current of carbon dioxide, through a heated tube filled with copper oxide, and the evolved nitrogen is measured over a solution of caustic potash. It was not found necessary to introduce a reduced copper spiral into the combustion tube. Some comparative results obtained with the different methods are given. —G. W. McD.

Explosion; Circumstances attending an — which occurred in the corning house of the gunpowder factory at Blackbuck, in the county of Lancaster, on July 15th, 1909. Major A. Cooper-Key, H.M. Chief Inspector of Explosives. [Cd. 4864.] (See also this J., 1906, 828.)

ABOUT half a ton of gunpowder was involved in this explosion, and two lives were lost. In the corning house the press-cake is, by means of a wooden hopper, passed between a pair of gun-metal toothed rollers, known as "crackers," which are kept almost in contact with one another by means of a suspended weight, so arranged that in the event of pressure arising between the crackers of sufficient force to lift the weight, they yield, and separate to a distance of about two inches, thus allowing the article causing the pressure to pass through before a dangerous degree of friction is set up. An examination of the debris after the accident brought to light certain indications pointing to the crackers as the seat of the original explosion. When passing the press-cake through the crackers, a piece will sometimes "play" on the rolls, and the workman is accustomed, in such cases, to turn the piece with a strip of copper. When clearing the debris, a piece of metal of this description was found, showing distinct marks of the teeth of the cracker rolls, and it is surmised that, whilst the workman was engaged in clearing the rolls, the piece of copper was dragged from his hand into the crackers, one end being at the same time embedded in the woodwork of the hopper in such a way as to cause sufficient friction to fire the powder. In future strips of ash or sycamore will be used instead of copper for the purpose of clearing the rolls. —G. W. McD.

Explosives used at mines and quarries in 1908. Mines and Quarries Report, 1908, Part II. [T.R.]

THE following table shows the amounts of the various explosives used at mines and quarries during 1908:—

Names of explosives.	Explosives used at			
	Mines under the Coal Mines Regulation Act.	Mines under the Metalliferous Mines Regulation Act.	Quarries under the Quarries Act.	Total Mines and Quarries.

* Explosives other than permitted explosives allowed under Section 6 of the Coal Mines Regulation Act, 1896.

PATENTS.

Explosive compounds. J. E. Holmes. Haliburton, Ont., Canada. Eng. Pat. 19,334, Sept. 15, 1908. Under Int. Conv., Dec. 28, 1907.

THE explosive consists of equal parts of finely-divided potassium chlorate and sugar, with the addition of 1 per cent. of sulphur.—G. W. McD.

Nitrocellulose; Process of dehydrating — G. W. Gentieu, Peoria, Ill. U.S. Pat. 931,749, Aug. 24, 1909.

THE bulk of the water is removed from the nitrocellulose, whilst in the form of pulp, by means of centrifugal force. The mass is then sprayed with alcohol, the rotation of the machine being meanwhile continued until the remainder

of the water has been expelled, after which the speed is reduced to such an extent that the final product shall retain the right proportion of alcohol.—C. A. M.

Charges for projectiles; Process for the preparation of — Dynamit Act.-Ges. vorm. A. Nobel und Co. Ger. Pat. 212,169, April 17, 1907.

It is stated that by cooling to about 0° C., the shell or other receptacle into which fused trinitrotoluene (or other suitable nitro-hydrocarbon) is introduced, the density of the solid explosive is increased to about 1.6.—A. S.

Fireworks; Manufacture of — Berthier et Cie. Fr. Pat. 398,859, April 4, 1908.

CLAIM is made for a composition consisting of 1 part of magnesium powder, 2 parts of barium nitrate, and half a part of an inert substance.—A. S.

Explosive. C. Clément and J. Langhard, Assignors to G. Grobet, Vallorbe, Switzerland. U.S. Pat. 933,060, Sept. 7, 1909.

SEE Fr. Pat. 351,793 of 1905; this J., 1905, 903.—T. F. B.

Nitrating oils. Fr. Pat. 398,748. See XII.

XXIII.—ANALYTICAL CHEMISTRY.

APPARATUS.

PATENTS.

Gas; Apparatus for analysing — O. Rodhe, Stockholm, Sweden. Eng. Pat. 18,829, Sept. 8, 1908.

THE lower part of the apparatus (see Fig.) is filled with mercury to the level, 65. The tube, 36, is connected to a supply of compressed air and 43 to the supply of gas to be analysed. The absorption pipette, 45, is filled with the absorbing liquid to the level, 66. The tube, 42, is closed by a liquid seal in 46. The bulb, 50, and the lower tube of bulb, 51, are filled with liquid to the level, 67. If compressed air is now admitted at 36, the mercury rises in tubes, 37, 38, and 65, until tubes, 68, 69, and 43, are sealed. The known volume of gas in bulb, 41, will, as the pressure increases, be forced over through the tube, 44, into the absorption pipette, 45, and any unabsorbed gas will collect in the upper part of this pipette, force the liquid in bulb, 50, into bulb, 51, and consequently force the air in 51 through the tube, 56, into the measuring bell, 59, where the volume is automatically recorded by the pencil, 62, on the rotating drum, 63. As soon as the whole of the gas has been forced over from the bulb, 41, into the absorption pipette, the level of the mercury in 35 has reached the opening of the

tube 37, the compressed air passes up this tube, and the conditions are automatically reduced to atmospheric pressure once more—the mercury falling in all the tubes to the original level, 65; a fresh quantity of gas is thus drawn in through the tube, 43, into the bulb, 41, ready for another determination, the bell, 59, sinking again to its original position.—G. W. McD.

Pyrometer. C. E. Foster, Rochester, N.Y. U.S. Pat. 933,543, Sept. 7, 1909.

The pyrometer consists essentially of a casing having an aperture at one end, which is exposed to the body of which the temperature is to be measured. Inside the casing are fixed a device sensitive to heat and an optical condensing device, which has one of its conjugate foci at the aperture and the other at the device sensitive to heat, the latter being protected from rays proceeding through the aperture directly from the hot body. Means are provided for measuring the effect produced on the device sensitive to heat by the rays concentrated thereon by the optical condensing device.—A. S.

Dropping pipette. Bachfeld and Co. Ger. Pat. 211,977, Jan. 6, 1909.

The tube of the pipette ends below in a short piece of glass rod with roughened surface, immediately above which is a capillary opening in the side of the tube. It is stated that by this arrangement, drops of equal size are delivered from the pipette.—A. S.

Testing fluids; Method and apparatus for —. H. B. Bishop, Assignor to General Chemical Co., New York. U.S. Pat. 933,015, Aug. 31, 1909.

SEE FR. Pat. 394,107 of 1908; this J., 1909, 222.—T. F. B.

INORGANIC—QUALITATIVE.

Isolate in commercial potassium iodide. Andrews. See VII.

INORGANIC—QUANTITATIVE.

Sulphuric acid; Precipitation of — as barium sulphate in solutions containing chlorides. I. F. Sacher. Chem.-Zeit., 1909, 33, 941—942.

RUPPIN (Chem.-Zeit., 1909, 398) concluded that sulphuric acid was not quantitatively precipitated as barium sulphate in a solution containing chlorides of alkali or alkaline-earth metals. The author, in reply, cites experiments to show that the deficiencies observed by Ruppinn were due to the solubility of the barium sulphate in potassium chloride solution. He has found that barium sulphate is also soluble in aqueous solutions of ammonium chloride, sodium chloride, calcium chloride, sodium chlorate, potassium chlorate, potassium bromide, and sodium nitrate. The solubility increases with the temperature and the concentration of the salt solution. It is increased by the presence of free hydrochloric acid, but reduced by bases. The most suitable conditions for the precipitation are the addition of a relatively large excess (about 3 times the theoretical amount) of 3 per cent. barium chloride solution to a very dilute solution of the sulphate, rendered very slightly acid with hydrochloric acid (about 1 c.c. of $N/5$ hydrochloric acid per 100 c.c.). The precipitation is made with both liquids at the boiling point, and the precipitate allowed to stand for at least 14 hours before filtration. When the proportion of hydrochloric acid was considerably greater and the excess of barium chloride was less, the results were too low. For the precipitation of sulphuric acid from potassium sulphate in the absence of potassium chloride, the addition of the hydrochloric acid was of little consequence, and so large an excess of barium chloride was unnecessary. The rate of the change of amorphous barium sulphate into the crystalline form depends upon the condition of the solution. In strongly acid liquids the change takes place in a few moments; it

is also brought about by heat. The speed of formation of the crystalline condition is accelerated with increase in the amount of the precipitant. If the precipitation be made in the cold in a neutral or slightly alkaline solution, the barium sulphate remains longer in the amorphous state. The presence of colloids such as albumin and gelatin also retards the formation of the crystalline form. These facts have a bearing on the technical manufacture of permanent white (*blanc fixe*). The product with the best covering power and in the finest state of division is obtained by precipitating the barium sulphate from a dilute solution of barium chloride at the ordinary temperature. The same remarks apply to the precipitation of other substances, such as calcium carbonate, calcium oxalate, magnesium ammonium phosphate, various lead salts, the sulphides of heavy metals, and numerous antimony compounds.—C. A. M.

Lead and bismuth; Quantitative separation of —. J. C. Galletly and G. G. Henderson. Analyst, 1909, 34, 389—391.

STAHLER and Scharfenberg (this J., 1906, 41), and Salkowski (*ibid.*), described methods of separating bismuth from other heavy metals in the form of phosphates. Lead and bismuth are quantitatively precipitated together as phosphates, and the authors have tried various methods of separating the mixed phosphates by digestion with dilute nitric acid, as suggested by Staehler and Scharfenberg. They find that, although it is possible in certain cases, to obtain satisfactory results in this way, the variations under similar conditions are so great as to render the process unreliable. They were also unable to obtain good results with the persulphate method of Dittrich and Reise (this J., 1905, 691), the electrolytic method of Balachowsky (this J., 1900, 855) and the electrolytic method of Holland and Bertiaux (this J., 1904, 839). With Clarke's method of separation, however, (this J., 1900, 26), the results were accurate. It is suggested as an improvement that the bismuth should be precipitated as phosphate, instead of with ammonium carbonate as described in the original method.—C. A. M.

Thiocyanic acid; Volumetric determination of — by means of potassium permanganate. K. Schröder. Z. offentl. Chem., 1909, 15, 321—336.

As the result of numerous experiments the author finds that thiocyanic acid cannot be accurately determined by direct titration with potassium permanganate solution, the results being too low. The reaction is approximately quantitative according to the equation: $\text{HCN} + \text{O}_2 = \text{SO}_2 + \text{HCN}$, when $N/10$ solutions are employed and when the manganese is precipitated by sodium carbonate, redissolved in hydrochloric acid, and again titrated. With more dilute solutions it is necessary to exclude atmospheric oxygen to obtain fairly accurate results. The thiocyanic acid (thiocyanate) may, however, be correctly determined by adding a definite volume of the thiocyanate solution to a known excess of warmed potassium permanganate solution acidified with sulphuric acid and phosphoric acid, decomposing the excess of permanganate by the addition of an excess of either standardised oxalic acid solution or hydrogen peroxide, and titrating the latter with permanganate.—W. P. S.

Silver; Iodometric determination of — based upon the reducing action of potassium arsenite. R. S. Bosworth. Amer. J. Sci., 1909, 28, 287—290.

SILVER, either in solution or in the form of the precipitated chloride, may be rapidly determined by adding an excess of standard potassium arsenite solution, boiling in the presence of ammonia or other alkali, until the silver salt is completely reduced, according to the equation: $2\text{Ag}_2\text{O} + \text{As}_2\text{O}_3 = \text{As}_2\text{O}_5 + 4\text{Ag}$, and then titrating the excess of arsenite with iodine, after acidifying and adding excess of sodium bicarbonate in the usual way; filtration from the reduced silver is not necessary.—F. SODS.

Cerium; Simplification of Mosander's method for the separation of — from the other cerite earths. O. Hauser and F. Wirth. *Z. anal. Chem.*, 1909, **48**, 679—692.

THE authors find that chlorine has no effect on an aqueous suspension of the peroxide formed when cerium, in the cerous state, is oxidised by hydrogen peroxide, in the presence of alkali; whereas lanthanum, neodymium, and praseodymium in like circumstances, are dissolved. The following process, based on these facts, is given for the separation of cerium from these elements. A slight excess of ammonia is added to the solution, containing 50—100 grms. of the oxides, and a 3 per cent. solution of hydrogen peroxide, free from phosphoric acid, is added in small portions, until the yellow colour of the hydroxide is no further deepened, any large excess of the reagent being avoided. A brisk current of chlorine is then led through the suspension, which is vigorously stirred, preferably by a mechanical arrangement; lanthanum is quickly dissolved, and ultimately the didymium earths also go into solution, but no trace of cerium is dissolved, if a harmful excess of hydrogen peroxide has been avoided. In order to get rid of any didymium yet present, however, the washed precipitate is dissolved in hot dilute nitric acid, a little hydrogen peroxide is added, and the above process is repeated.—F. SODN.

Electro-analysis; Report of the British Association Committee on —. *Electrician*, 1909, **63**, 919.

(1). EXPERIMENTS on the electro-deposition of mercury upon cathodes of gold, silver, platinum, and mercury, show that the use of mercury furnishes the only really satisfactory method of deposition (see also this J., 1909, 493), and a new electrolysing vessel of quartz has been designed for this purpose. It consists of a small quartz beaker, capable of holding about 80 c.c. of solution, with a siphon fused into it about 0.5 cm. from the bottom, contact being made by a piece of iridium wire, fused into the bottom of the beaker. The solution to be electrolysed is placed above the mercury, and the spiral anode rotated at 500—750 turns per min. The mercury is deposited in 20—30 minutes, and then, by pouring in water, the siphon is made to act, the addition of water being continued, until the ammeter indicates zero; the water is then replaced by 90 per cent. alcohol, and this by absolute alcohol, and finally the mercury is washed twice with dry ether and the surface is dried by blowing air over it for about 10 minutes. (2). Sand's apparatus for the electro-deposition of metals by graded potential (this J., 1907, 490; 1908, 963) has been modified in several particulars, in order to make it more portable and readily set up. (3). Experiments to ascertain the cause of discrepancies which have been observed in the deposition of lead as peroxide, have shown that lead peroxide is liable to take up water, and it is recommended, that deposition should take place at 90°—95° C., when the deposit, after drying with alcohol and ether, contains only about 1/3 per cent. of water.—F. SODN.

Thallium; Electrolytic determination of —. G. W. Morden. *J. Amer. Chem. Soc.*, 1909, **31**, 1045—1048.

THALLIUM is readily deposited by the action of an electric current, but the chief difficulty in the electrolytic determination is the prevention of oxidation of the deposited metal. The author has made a number of experiments in which the separated thallium was covered with a coating of zinc, but there was an uncertainty in obtaining a good, non-porous coating of the latter metal. It was found, however, that trustworthy results could be obtained by the formation of a dilute zinc amalgam by electrolysis of a zinc sulphate solution in the ordinary mercury cup and the use of the zinc amalgam thus obtained as the cathode for the deposition of the thallium. The usual method of procedure with the mercury cathode was followed. Experiments made to ascertain the minimum quantity of zinc necessary to prevent oxidation of the thallium, showed that with as small a quantity as 0.0007 gm. of zinc present, the wash water was free from

thallium when the amalgam contained 0.1142 gm. of the latter metal. Good results were also obtained with a cadmium-thallium amalgam.—W. P. S.

ORGANIC—QUANTITATIVE.

Phosphoric acid; Determination of — in organic substances. H. Schaumann. *Z. anal. Chem.*, 1909, **48**, 612—617.

A WEIGHED quantity of the substance, such as excreta, animal organs, or foods, containing not more than 0.1 gm. of phosphoric acid, is placed in a flask of from 250 to 500 c.c. capacity, and heated with from 10 to 25 c.c. of a mixture of equal parts of concentrated sulphuric and nitric acids. Should the solution remain dark in colour after continued heating, a little more nitric acid is added and the mixture is again heated until a colourless or faintly yellow solution is obtained, and most of the nitric acid is expelled. After cooling, about 30 c.c. of water are added, the solution is boiled, filtered if necessary, and transferred to a flask of about 500 c.c. capacity into which 50 c.c. of 50 per cent. ammonium nitrate solution have been previously introduced. Forty c.c. of 10 per cent. ammonium molybdate solution are then added, and the mixture is kept at a temperature of from 50° to 60° C. for 18 hours. The precipitate is now collected on an asbestos filter, washed with water until free from acidity, and then dissolved in a known volume (say 10 c.c.) of N/2 sodium hydroxide, the solution being collected in the precipitation flask. The filter is washed with about 100 c.c. of water, the washings being also collected in the flask, and the contents of the latter are next boiled until all ammonia has been removed. After the addition of a few drops of phenolphthalein solution, the solution is titrated with N/2 hydrochloric acid until the coloration disappears, N/2 sodium hydroxide is then run in until the red coloration reappears, the solution is boiled for 2 minutes, and finally titrated with N/2 hydrochloric acid. The difference between the total quantities of N/2 sodium hydroxide and N/2 hydrochloric acid used corresponds with the amount of phosphoric acid present. Each c.c. of N/2 sodium hydroxide is equivalent to 0.001268 gm. of phosphoric acid (P₂O₅) or 0.0005536 gm. of phosphorus.—W. P. S.

XXIV.—SCIENTIFIC & TECHNICAL NOTES.

- Silkworm; Presence of an enzyme in the —, which produces ammonia from amino-compounds.* T. Takeuchi and R. Inouye. J. Coll. Agric., Imp. Univ., Tokyo, 1909, 1, 15—20.

THE juice expressed from crushed silkworms, especially from the moths, contains an enzyme which is capable of splitting certain amino-compounds with the production of ammonia. The authors have isolated an active preparation by precipitation with alcohol and have examined its action on various amino-compounds at a temperature of 28° C. The enzyme only acts when the medium is made faintly alkaline; it exerts a very pronounced action on asparagine and acts more feebly on urea, biuret, leucine, and glycocoll; certain other amino-compounds, e.g., tyrosine, guanidine, etc., are not attacked. Asparagine apparently yields succinic acid as a cleavage product together with ammonia.—J. E. B.

- Fat in the black walnut (*Juglans nigra*); Development of —.* F. M. McClenahan. J. Amer. Chem. Soc., 1909, 31, 1093—1097.

THE results of observations on the development of the black walnut are given. Starch, sugar, and tannin were found to be absent from the kernel at all periods of its development, but tannin was markedly present in the hull and tissue of the kernel capsule. When the kernel was entirely liquid, there was a pronounced pressure in the capsule. The first formation of the jelly-like kernel was on the interior surface of the capsule; this gradually changed to a white solid, whilst the jelly-like formation retreated towards the centre of the chamber, replacing in turn the liquid and finally itself being replaced by the solid kernel. The fat increased out of all proportion to the increase or decrease of the other constituents. From these observations it is evident that the fat in the walnut is not formed from starch, sugar, or tannin within the capsule of the kernel, nor is it formed from the decomposition products of the crude fibre, proteins, and pentosans. The author suggests that it is possible that the tannin in the tissue of the kernel may afford material from the decomposition products of which the fat is built up. These decomposition products enter the capsule by osmosis, as there is no fluid circulation between the capsule and other parts of the nut.—W. P. S.

- Sugars; Decomposition of the —.* I. Provisional communication. *Reversion of the synthesis of sugar.* W. Löb. Biochem. Zeits., 1909, 20, 516—522. (See this J., 1909, 617.)

PREVIOUS experiments have supported von Baeyer's theory of the rôle of formaldehyde in the synthesis of

sugar, and have led the author to the conclusion that the same compound, or rather a tautomeric, active form of it, plays a special part in the decomposition of sugar that occurs in physiological combustion and fermentation. Granting that formaldehyde can occur in an intermediate labile form, it must be admitted that the latter can undergo (1), synthesis to carbohydrates or other substances; and, (2), rearrangement to stable formaldehyde. In reference to the synthesis of a hexose from formaldehyde in presence of hydroxyl ions, a reaction which the author regards as reversible, the phase of this reaction represented by the equation, $C_6H_{10}O_5 + (H_2O) = C_6H_{12}O_6$, is discussed. If this is the course of the action, its reversible nature shows that in the decomposition of sugar the opposed course is of importance. The author has found that dextrose may be converted into pentose and formaldehyde by inversion of the synthesis of sugar from formaldehyde with lead hydroxide at 70° C. according to the method of Lobry de Bruyn and van Ekenstein. Thus, if a 4 per cent. solution of dextrose is allowed to stand, at 70° C., with 0.8 per cent. of freshly precipitated and well washed lead hydroxide, pentose and formaldehyde, besides polyhydroxy-acids and formic acid (and probably polyhydric alcohols), are formed. Again, by the action of sodium hydroxide on dextrose, both at ordinary and slightly higher temperatures, pentose and formaldehyde are obtained; the accompanying reactions are more complicated than in the previous case; an alkalinity corresponding to that of the blood, is sufficient, at incubator temperatures, to effect the decomposition into pentose and formaldehyde, and, in the light of this result, the author discusses the physiological combustion of sugar. In conclusion, he considers that the sugar suffers a kind of dissociation which, on the one hand, leads to decomposition by oxidation processes, and, on the other, gives opportunity to new syntheses of the cleavage-products in various directions. This dissociation and the subsequent synthesis, cause the inter-conversion of the sugars, the occurrence of the different sugars in nature, and the formation of a series of reaction-products of anaerobic respiration or intramolecular oxidation to which a part of the phenomena of fermentation belongs.—L. E.

- Oxydases; Employment of hydrogen peroxide in experiments on —.* T. Kikkoji and C. Neuberg. Biochem. Zeits., 1909, 20, 523—525.

IN experiments on the action of "tyrosinases," addition of hydrogen peroxide or of hydrogen peroxide and ferrous sulphate, is often made. In presence of iron salts, however, hydrogen peroxide acts on a large number of the aromatic compounds used in experiments on oxydases, yielding dark colorations, or brown or black precipitates, which are not identical with the "melanins." In most experiments on tyrosinases at the present time, however, the dark coloured products are not examined chemically. Hence, the possibility of their formation by other than true enzyme actions, or by chemical and fermentative actions superposed, must be considered. Since, also, many enzyme solutions contain iron, caution must be observed in the use of hydrogen peroxide in oxydase actions. The views concerning these actions require modification in the light of the experiments of Euler and Bolin (Z. physiol. Chem., 1908, 57, 80). The authors describe the colorations or precipitates obtained from various compounds by the action of hydrogen peroxide and iron (ferrous or ferric) salts, and give a method whereby the product from phenol may be obtained in quantity.—L. E.

Trade Report.

- The Tariff Commission on Chemicals.* Chem. and Drugg., Sept. 18, 1909.

THE latest memorandum by the Tariff Commission analyses the course of the export trades in leading manufactures of the United Kingdom, Germany and the United

States in order to illustrate (a) the comparative growth of the export trade in the principal manufactures under the tariff systems of the three countries; (b) the magnitude and growth of the trade of these countries with groups of protected countries; (c) the growth of German trade in manufactures with the central European group of countries with which Germany has special commercial treaties; and (d) the extent and growth of the trade of each country with the British Empire since the adoption of Colonial preferences. The memorandum is published by P. N. King and Son, 2 and 4, Great Smith Street, Westminster, S.W., at 3d. As regards chemicals the Commission says the export from Germany has made far greater advance than that of the United Kingdom or the United States. The increases in the last twelve years have been: Germany, £11,250,000; United Kingdom, £5,500,000; and the United States, £2,250,000. German exports, which were £2,000,000 larger than those of the United Kingdom in 1895, are now £7,750,000 larger. The United Kingdom trade with protected markets has remained practically stationary, while the German trade has nearly doubled. The facts as stated are set forth in a series of tables.

£30,822,211. or, after deduction of drawbacks and repayments, to £29,158,057, which is £41,943, or 0.14 per cent., less than the Budget estimate for the year, and £3,423,937, or 10.5 per cent., less than the net yield for 1907-8.

The largest items in the total Customs receipts during the last two financial years were as follows:—

Gross produce of Customs Duties (excluding duties collected in the Isle of Man).

	Year ended 31st March.

Books Received.

MINES AND QUARRIES. GENERAL REPORT AND STATISTICS FOR 1908. PART II. LABOUR. [Cd. 4877.] Wyman and Sons, Fetter Lane, E.C. Price 10d.

This volume contains an account of the number of persons employed in mines and quarries in 1908, and also of accidents and prosecutions. Also a list of "permitted" explosives, a table showing the amount of explosives used in mines and quarries in 1908, and various other miscellaneous details. (See also under Class XXII.)

MINUTES OF EVIDENCE TAKEN BY THE ROYAL COMMISSION ON WHISKY AND OTHER POTABLE SPIRITS, WITH APPENDICES. Vol. II. [Cd. 4797.] Wyman and Sons, Fetter Lane, E.C. Price 2s. 6d.

This volume contains a list of the witnesses examined, 203 foolscap pages of minutes of evidence, and 13 appendices, containing analyses of whiskies, brandies, and rums, and other matters.

INDEX AND DIGEST OF EVIDENCE TAKEN BEFORE THE ROYAL COMMISSION ON WHISKY AND OTHER POTABLE SPIRITS. [Cd. 4876.] Wyman and Sons, Fetter Lane, E.C. Price 7d.

IMPORTS AND EXPORTS AT PRICES OF 1900. TABLES SHOWING FOR EACH OF THE YEARS 1900—1908 THE ESTIMATED VALUE OF THE IMPORTS AND EXPORTS OF THE UNITED KINGDOM AT THE PRICES PREVAILING IN 1900, WITH AN INTRODUCTORY MEMORANDUM. [Cd. 4867.] Price 2½d.

This return, which has been prepared in the Commercial, Labour and Statistical Department of the Board of Trade, is issued in continuation and extension of that issued last year [Cd. 4115, 1908], in which a detailed comparison was made, in respect of each year since 1900, between the values of the various groups of imports and exports as actually declared and the estimated values of such groups based on the average values obtaining in 1900. The object of this series of returns is to eliminate as far as possible the effect of the fluctuation of prices, and so secure a basis for a closer comparison between the volume of imports and exports in each year.

FIFTY-THIRD REPORT OF THE COMMISSIONERS OF HIS MAJESTY'S CUSTOMS (FOR THE YEAR ENDED 31st MARCH, 1909). [Cd. 4862.] Price 4d.

ACCORDING to this report, the gross Imperial Customs revenue collected in the year 1908-9 amounted to

QUANTITATIVE CHEMICAL ANALYSIS ADAPTED FOR USE IN LABORATORIES OF COLLEGES AND SCHOOLS. By F. CLOWES, D.Sc., Lond., and J. B. COLEMAN, A.R.C.Sc., Dublin. Eighth edition. J. and A. Churchill, 7, Great Marlborough Street, London. 1909. Price 10s. 6d. net.

Svo volume containing 543 pages of subject matter, an index to separations, and a general index. The work is subdivided as follows:—PART I. General processes. (i.) The chemical balance, weights, and weighing. (ii.) Determination of specific gravity, melting point, and boiling point. (iii.) Mechanical preparation of solids. Drying, solution, evaporation, filtration, etc. PART II. (iv.) Simple gravimetric estimations. PART III. Volumetric analysis. (v.) Measurement of liquids. Calibration and use of graduated vessels. Indicators. Standard solutions. (vi.) Alkalimetry and acidimetry. (vii.) Oxidation and reduction processes. (viii.) Unclassified estimations. PART IV. General quantitative analysis. (ix.) Technical analysis, including analysis of alloys, minerals, soda-ash, salt-cake, glass, iron and steel, coal and coke, and fertilisers; also dry assay for lead, silver, gold, and tin. (x.) Water analysis. (xi.) Food analysis. Valuation of tanning materials. Soap analysis. (xii.) Examination of oils, fats, and waxes. PART V. (xiii.) and (xiv.) Organic analysis and molecular weights. PART VI. Volumetric estimation of gases. PART VII. Tables for reference, including results of typical analyses, specific gravities of solutions of alcohol and acids and alkalis, constants of oils, fats, and waxes, English and metric weights and measures, logarithms, etc. PART VIII. Preparation of gases. Use of compressed gases. Distillation of water, etc.

AMERICAN MEDICINAL BARKS. ALICE HENKEL. U.S. Dept. of Agric., Bureau of Plant Industry, Bulletin No. 139, Washington, June 3, 1909.

This bulletin of 51 pages forms the second instalment on the subject of American medicinal plants, the first one having dealt with root drugs. Thirty-five drugs, derived from barks, are described and illustrated, and briefer information concerning closely related species is included. The barks described are white pine (*Pinus strobus*), tamarack (*Larix laricina*), aspen (*Populus tremuloides*), white willow (*Salix alba*), bayberry (*Myrica ripens*), bitter-nut (*Juglans cinerea*), ironwood (*Ostrya virginiana*), sweet birch (*Betula lenta*), tag-alder (*Alnus rugosa*), white oak (*Quercus alba*), slippery elm (*Ulmus pubescens*), magnolia (*Magnolia acuminata*, *M. tripetala*, and *M. glauca*), tulip-poplar (*Liriodendron tulipifera*), sassafras (*Sassafras sassafras*), spicebush (*Benzoin benzoim*), witch-hazel (*Hamamelis virginiana*), blackberry (*Rubus villosus*, *R. nigrobaccus*, and *R. cuneifolius*), American mountain ash (*Sorbus americana*), wild cherry (*Prunus serotina*), prickly ash (*Xanthoxylum americanum* and *X. clavaherculis*), wafer-ash (*Ptelea trifoliata*), black alder (*Ilex*

verticillata), wahoo (*Euonymus atropurpurea*), false bittersweet (*Celastrus scandens*), horse-chestnut (*Aesculus hippocastanum*), cascade sagrada (*Rhamnus purshiana*), cotton (*Gossypium hirsutum*), dogwood (*Cornus florida*), moose-wood (*Dirca palustris*), white ash (*Fraxinus americana*), fringe tree (*Chionanthus virginica*), bitter-sweet (*Solanum dulcamara*), hutton-bush (*Chapmanthus occidentalis*), cramp-bark tree (*Viburnum opulus*), and black haw (*Viburnum prunifolium*).

Patent List.

Where a Complete Specification accompanies an Application, an asterisk is affixed. The dates given are (i) in the case of Applications for Patents, the dates of Application, and (ii) in the case of Complete Specifications Accepted, those of the Official Journals in which acceptances of the Complete Specifications are advertised.

Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

I.—PLANT, APPARATUS, AND MACHINERY.

APPLICATIONS.

20,871. Southern. *See under VII.*

20,880. Leask. Apparatus for cooling water or treating gases with liquids. Sept. 13.

21,050. Hatschek. Apparatus for filtering through layers of finely-divided material. Sept. 15.

21,293. Held. *See under XVII.*

21,369. Cambridge Scientific Instrument Co., and Whipple. Radiation pyrometers. Sept. 18.

21,418. Tattersall. Apparatus for evaporating and cooling liquids.* Sept. 20.

21,582. Pritchard, and United Alkali Co., Ltd. Apparatus for utilising heat from liquors discharged from stills, etc. Sept. 21.

21,660. Maschinenfabr. F. Weigel Nachfolger, and Spielvogel. Filter-press.* Sept. 22.

21,862. Pedersen. Centrifugal separators. Sept. 25.

COMPLETE SPECIFICATIONS ACCEPTED.

19,668 (1908). Hommel, and Metals Extraction Corporation. Liquid distributors for absorbing towers. Sept. 22.

20,244 (1908). Carr. Apparatus for controlling or deflecting the flow of flue gases, especially for use with CO₂ recorders. Sept. 29.

21,095 (1908). Kirchberg. Reverberatory furnace. Sept. 29.

21,474 (1908). Wöhl and Tarbutt. Filtering apparatus for use in washing slimes, &c. Sept. 22.

23,001 (1908). Challis. Filtration. Sept. 22.

3250 (1909). Vallery. Saturating device for liquids. Sept. 29.

12,056 (1909). Fate. Means for indicating loss of vacuum in vacuum chambers. Sept. 29.

12,958 (1909). Seaver. Apparatus for separating finely divided materials. Sept. 22.

II.—FUEL, GAS, AND LIGHT.

APPLICATIONS.

20,906. Sheppard. Manufacture of fuel blocks. Sept. 13.

20,975. Fritz. Purifying fuel and increasing its heating power. Sept. 14.

21,003. Graf and Smyth. Gas for lighting, heating, and power. Sept. 14.

21,010. Otto und Co. Recovery of by-products from gases derived from combustibles. [Ger. Appl., Oct. 7, 1908.]* Sept. 14.

21,674. Betts. Process for utilising coal.* Sept. 22.

21,942 and 21,947. Werber. Manufacture of mantles for incandescent gas lighting. [Austrian Appl., March 20 and June 5, 1909.]* Sept. 25.

COMPLETE SPECIFICATIONS ACCEPTED.

17,603 (1908). Glasgow. Manufacture of water-gas. Sept. 29.

18,672 (1908). Kaysser. Protecting iron walls of gas-holders from the cyanogen compounds entering the water of the seal. Sept. 22.

19,264 (1908). Act.-Ges. f. Kohlendestillation. Regenerative coke ovens. Sept. 22.

24,332 (1908). Thom and Pryor. Retort furnaces for making gas, etc. Sept. 22.

8940 (1909). Hill and Westwood. Apparatus for making a combustible heating and illuminating gas. Sept. 29.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

APPLICATIONS.

21,007. Pichon and Truchelut. Utilising chlorides of carbon for rendering benzine, turpentine, chloroform, alcohol, ether, &c., non-inflammable.* Sept. 14.

21,153. Fabri. Deodorisation and treatment of mineral and like oils. Sept. 16.

21,789. Fabri. Deodorising mineral oil from shale for burning purposes. Sept. 24.

COMPLETE SPECIFICATION ACCEPTED.

13,252 (1908). Heinemann. *See under XVI.*

IV.—COLOURING MATTERS AND DYE STUFFS.

APPLICATIONS.

20,905. Newton (Bayer und Co.). Manufacture of a dyestuff of the oxazine series and its leuco-derivative. Sept. 13.

21,578. Johnson (Kalle und Co.). Manufacture of sulphur-containing matters for vat dyeing. Sept. 21.

21,579. Johnson (Kalle und Co.). Manufacture of reduction products of acenaphthenequinone and of leuco-compounds of vat dyestuffs. Sept. 21.

21,580. Johnson (Kalle und Co.). Manufacture of new compounds and colouring matters. Sept. 21.

21,581. Johnson (Kalle und Co.). Manufacture of brominated colouring matters of the thioindigo group.* Sept. 21.

COMPLETE SPECIFICATIONS ACCEPTED.

25,551 (1908). Imray (Meister, Lucius, und Brüning). Manufacture of vat dyestuffs of the anthracene series. Sept. 22.

657 (1909). Newton (Bayer und Co.). Manufacture of azo dyestuffs. Sept. 22.

6831 (1909). Newton (Bayer und Co.). Manufacture of 1,8-diaminonaphthalene-4-sulphonic acid. Sept. 22.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

APPLICATIONS.

21,024. Kemp. Dyeing and washing machines. Sept. 14.

21,203. Turnbull and Turnbull. Dyeing and washing machines. Sept. 16.

21,535. Lundeborg. Pressed fabric and its manufacture. Sept. 21.

21,714. Owens. *See under XI*X.

COMPLETE SPECIFICATIONS ACCEPTED.

20,743 (1908). Kur. Dyeing and sizing, or dyeing and starching in one operation, yarns or fabrics of vegetable fibres. Sept. 29.

24,810 (1908). Newton (Bayer und Co.). Process of dyeing and printing. Sept. 29.

26,460 (1908). Newton (Bayer und Co.). Dyeing with oxyanthraquinone dyestuffs. Sept. 29.

VII.—ACIDS, ALKALIS, AND SALTS.

APPLICATIONS.

20,871. Southern. Calcining limestone and other inorganic substances. Sept. 13.

20,893. Imray (Meister, Lucius, und Brüning). Manufacture of concentrated formic acid from formates. Sept. 13.

20,907. Nydegger, and Wedekind und Co. Manufacture of pure ammonium nitrate. Sept. 13.

21,032. Cons. f. Elektrochem. Industrie. Production of hydrogen. [Ger. Appl., Nov. 9, 1908.]* Sept. 14.

21,884. Gill. Manufacture of ferric oxide. [Addition to No. 5618 of 1909.] Sept. 25.

COMPLETE SPECIFICATIONS ACCEPTED.

19,402 (1908). Hurford. Obtaining nitrogen from atmospheric air. Sept. 22.

22,824 (1908). Soc. d'Electro-Chimie, and Hulin. *See under XI*.

27,302 (1908). Carulla. Manufacture of ammonium salts and iron oxide from ferrous liquors. Sept. 22.

15,997 (1909). Serpek. Manufacture of ammonia from aluminium nitride. Sept. 22.

VIII.—GLASS, POTTERY, AND ENAMELS.

APPLICATIONS.

21,063. Davies. *See under IX*

21,123. Lewis. *See under IX*.

COMPLETE SPECIFICATIONS ACCEPTED.

2294 and 2295 (1909). Salamon, Grace, and Exploration Co. Preparation of china clay. Sept. 29.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

APPLICATIONS.

21,063. Davies. Kilns for burning bricks and pottery. Sept. 15.

21,123. Lewis. Kilns for making bricks or other clay or ceramic goods. Sept. 15.

• 21,670. Sinclair. Cement. [U.S. Appl. Sept. 22, 1908.]* Sept. 22.

X.—METALS AND METALLURGY.

APPLICATIONS.

21,419. Hodgkinson. Carburising iron or mild steel in iron alloys. Sept. 20.

21,497. Batchelor and Batchelor. Recovery of tin and iron from tinplate scrap.* Sept. 21.

21,584. Isherwood. Treatment of refractory zinc-lead ores. Sept. 21.

21,612. Ruthenburg. Metallurgical and like furnaces. Sept. 22.

21,676. Webb and Webb. Treatment of iron or steel. Sept. 22.

21,718. Diehl. Process for winning metals. Sept. 23.

21,768. Zohrab and Evans. Treatment of refractory ores, iron sands, and other small or waste ores.* Sept. 23.

21,923. Vautin. Wet separation of copper from its ores or compounds. Sept. 25.

COMPLETE SPECIFICATIONS ACCEPTED.

12,962 (1908). Lockwood and Samuel. Treatment of ores. Sept. 29.

19,667 (1908). Hommel, and Metals Extraction Corporation. Furnaces for volatile metals. Sept. 22.

22,337 (1908). Von Schütz. Detinning tin plate waste, &c., by means of chlorine. Sept. 29.

24,007 (1908). Johnson (Chem. Fabr. Griesheim Elektron). Preparation of iron or steel for casting. Sept. 29.

27,025 (1908). Frölich. Process of obtaining cement copper. Sept. 29.

2849 (1909). Pyrotrass Soc. Anon. Granulating slag. Sept. 22.

2938 (1909). Sebillot and Maucclair. Apparatus for recovering metalliferous fumes obtained in roasting or smelting ores. Sept. 29.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

COMPLETE SPECIFICATIONS ACCEPTED.

22,824 (1908). Soc. d'Electro-Chimie, and Hulin. Apparatus for the electrolytic production of sodium and the like. Sept. 29.

605 (1909). Siemens Bros. and Co. (Siemens und Halske A.-G.). Electrolysis of aqueous saline solutions. Sept. 22.

4553 (1909). Aktiebolaget Elektrometall. Electric furnace. Sept. 29.

XII.—FATTY OILS, FATS, WAXES, AND SOAPS.

APPLICATIONS.

21,457. Bauer. Preparation of soft soap.* Sept. 20.

21,742. Kobe. Manufacture of cleansing preparations. [Ger. Appl., Nov. 26, 1908.]* Sept. 23.

COMPLETE SPECIFICATIONS ACCEPTED.

19,511 (1908). Lake (Comp. Luz Stearica). Treatment of the nut of the bieuyba. Sept. 22.

26,857 (1908). Jacekels. Manufacture of soap. Sept. 29.

691 (1909). Egeberg. Apparatus for purifying oil. Sept. 29.

XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, &c.

(A.)—PIGMENTS, PAINTS.

APPLICATION.

21,163. Wakefield and Rathbone. Sanitary paint. Sept. 16.

COMPLETE SPECIFICATION ACCEPTED.

12,498 (1909). Dalby and Benson. Paint and like compositions. Sept. 22.

(C.)—INDIA-RUBBER.

COMPLETE SPECIFICATION ACCEPTED.

20,303 (1908). Gare. Manufacture of sheet rubber and rubber articles. Sept. 29.

XIV.—TANNING, LEATHER, GLUE, SIZE, &c.

APPLICATIONS.

21,202. Eberle. Process of bating hides. [Ger. Appl., Nov. 16, 1908.]* Sept. 16.

21,836. Dickson. Leather and process for preparing same. Sept. 24.

COMPLETE SPECIFICATION ACCEPTED.

4488 (1909). Lehmann. Treating hides and skins to remove grease, fat, oil, and lime, and for disinfecting. Sept. 22.

XV.—MANURES, &c.

COMPLETE SPECIFICATIONS ACCEPTED.

11,924 (1909). Johnson and Austin. Manufacture of manure. Sept. 22.

17,116 (1909). Pickering and Voss. Fungicides. Sept. 29.

XVI.—SUGAR, STARCH, GUM, &c.

COMPLETE SPECIFICATION ACCEPTED.

13,252 (1908). Heinemann. Conversion of carbohydrates into hydrocarbons. Sept. 29.

XVII.—BREWING, WINES, SPIRITS, &c.

APPLICATIONS.

21,173. Löblov. Manufacture in the form of grain of pure or mixed cultures of bacteria producing lactic fermentation.* Sept. 16.

21,293. Held. Iron vats, casks, &c., for brewers' use.* Sept. 17.

21,685. Boake, Roberts, and Co., Ltd., and Berry. Bleaching and fumigating hops. Sept. 23.

21,788. Fabri. Obtaining a greater proportion of ethyl alcohol from maize. Sept. 24.

COMPLETE SPECIFICATION ACCEPTED.

19,212 (1908). Schwensen and Lazarus. Process of saccharifying malt. Sept. 22.

XVIII.—FOODS; SANITATION, WATER PURIFICATION; AND DISINFECTANTS.

(A.)—FOODS.

APPLICATION.

21,753. Blenkinsop. Treatment of flour. Sept. 23.

COMPLETE SPECIFICATION ACCEPTED.

19,246 (1908). Evans. Manufacture of feeding cake. Sept. 22.

(B.)—SANITATION; WATER PURIFICATION.

APPLICATIONS.

21,184. Riedel. Removing iron from water and regenerating the purifying material. [Ger. Appl., Dec. 10, 1908.]* Sept. 16.

21,855. Edgeworth. Bacteriological treatment of sewage. Sept. 25.

21,929. Bevan. Furnaces for destroying injurious gases, &c. Sept. 25.

COMPLETE SPECIFICATION ACCEPTED.

6935 (1909). Payne and Staynes. Purification of water. Sept. 22.

XIX.—PAPER, PASTEBOARD, &c.

APPLICATIONS.

20,911. Kuess. Manufacture of pulp for making paper, &c. [Fr. Appl., Sept. 15, 1908.]* Sept. 13.

21,473. Deiss. Manufacture of cellulose.* Sept. 20.

21,714. Owens. Bleaching wood pulp or other vegetable fibres. Sept. 23.

COMPLETE SPECIFICATIONS ACCEPTED.

22,420 (1908). Lövinsohn. Manufacture of transfer papers. Sept. 29.

17,15 (1909). Galay and Galay. Air-proof and water-proof paper and films. Sept. 29.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENTIAL OILS, AND EXTRACTS.

APPLICATIONS.

21,007. Pichon and Truchelut. *See under III.*

21,173. Löblov. *See under XVII.*

21,174. Löblov. Enriching bacteria cultures. [Ger. Appl., May 29, 1909.]* Sept. 16.

21,948. Wetter (Blank). Manufacture of formaldehyde.* Sept. 25.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

APPLICATIONS.

20,891. Vigers. Preparation of paper for photographic purposes. Sept. 13.

21,281. Sury and Bastyns. Photographic printing in colours with the bichromate gelatin process.* Sept. 17.

XXII.—EXPLOSIVES, MATCHES, &c.

APPLICATIONS.

21,265. Middleton. Safety explosives. Sept. 17.

21,266. Middleton. Explosives. Sept. 17.

21,272. Hale. Manufacture of explosives. Sept. 17.

21,305. Hale. Manufacture of explosives. Sept. 17.

21,931. Johnson (Chem. Fabr. Griesheim-Elektron). Igniting compositions for matches, &c.* Sept. 25.

The Society of Chemical Industry.

Past Presidents.

Sir Henry E. Roscoe, B.A., D.C.L., LL.D., Ph.D., F.R.S.	1881—1882.
†Sir Frederick A. Abel, Bart., K.C.B., G.C.V.O., D.C.L., D.Sc., F.R.S.	1882—1883.
†Walter Weldon, F.R.S.	1883—1884.
†Sir Wm. H. Perkin, LL.D., Ph.D., F.R.S.	1884—1885.
E. K. Muspratt, LL.D.	1885—1886.
David Howard	1886—1887.
Sir James Dewar, M.A., LL.D., F.R.S.	1887—1888.
Ludwig Mond, Ph.D., F.R.S.	1888—1889.
†Sir Lowthian Bell, Bart., F.R.S.	1889—1890.
†E. Rider Cook	1890—1891.
J. Emerson Reynolds, M.D., D.Sc., F.R.S.	1891—1892.
†Sir John Evans, K.C.B., D.C.L., LL.D., Sc.D., F.R.S.	1892—1893.
†E. C. C. Stanford	1893—1894.
Sir Edward Thorpe, C.B., LL.D., Sc.D., Ph.D., F.R.S.	1894—1895.
Thomas Tyrer	1895—1896.
†Edward Schunck, Ph.D., F.R.S.	1896—1897.
Frank Clowes, D.Sc.	1897—1898.
George Beilby, LL.D., F.R.S.	1898—1899.
C. F. Chandler, D.Sc., M.D., Ph.D., LL.D.	1899—1900.
Sir Jos. W. Swan, D.Sc., M.A., F.R.S.	1900—1901.
Ivan Levinstein	1901—1903.
Sir Wm. Ramsay, K.C.B., D.Sc., LL.D., F.R.S.	1903—1904.
Wm. H. Nichols, M.S., LL.D., D.Sc.	1904—1905.
Edward Divers, M.D., D.Sc., F.R.S.	1905—1906.
Eustace Carey	1906—1907.
Sir Boverton Redwood, D.Sc.	1907—1908.
Raphael Meldola, F.R.S.	1908—1909.

† Deceased.

LIST OF COUNCIL, 1909—1910.

President: President Ira Remsen.

Vice-Presidents:

Dr. G. Beilby, F.R.S.	Dr. R. Messel.
Eustace Carey.	Sir Boverton Redwood.
Dr. J. T. Dunn.	Walter F. Reid.
E. Grant Hooper.	Geo. C. Stone.
A. R. Ling.	Dr. T. B. Wagner.
Prof. R. Meldola, F.R.S.	R. C. Woodcock.

Ordinary Members of Council:

Prof. P. Phillips Bedson.	D. Lloyd Howard.
Prof. W. Hodgson Ellis.	Dr. Charles A. Keane.
Oscar Guttman.	Prof. W. R. Lang.
H. Hemingway.	Harold Van der Linde.
Prof. G. G. Henderson.	B. E. R. Newlands.
Prof. W. R. E. Hodgkinson.	Dr. Julius Raschen.

Sectional Chairmen and Secretaries:

Dr. T. Slater Price.	BIRMINGHAM.	F. R. O'Shaughnessy.
Dr. Milton L. Hersey.	CANADIAN.	Alfred Burton.
Max Muspratt.	LIVERPOOL.	W. Roscoe Hardwick.
Dr. J. Lewkowitsch.	LONDON.	Julian L. Baker.
R. H. Clayton.	MANCHESTER.	Julius Hübner.
C. J. Potter.	NEWCASTLE.	Dr. F. C. Garrett.
Dr. W. H. Walker.	NEW ENGLAND.	Alan A. Clafin.
Maximilian Toch.	NEW YORK.	Dr. H. Schweitzer.
S. J. Pentecost.	NOTTINGHAM.	S. R. Trotman.
D. J. Playfair.	SCOTTISH.	Dr. G. B. Neave.
Prof. J. A. Schofield.	SYDNEY, N.S.W.	T. U. Walton.
Prof. W. M. Gardner.	YORKSHIRE.	Thomas Fairley.

Honorary Treasurer:

Thomas Tyrer, Stirling Chemical Works, Strathord, E.

Honorary Foreign Secretary:

Dr. Ludwig Mond, F.R.S.

General Secretary: Charles G. Cresswell, 59, Palace Chambers, Westminster, S.W.

Telegraphic Address: 59, Palatable, London.

Telephone Number: 715, Victoria.

THE JOURNAL.

Publication Committee.

The President.

Julian L. Baker.	J. Lewkowitsch, Ph.D.
J. Carter Bell.	A. R. Ling.
C. F. Cross.	W. Macnab.
Edw. Divers, M.D., D.Sc., F.R.S.	N. H. Martin.
T. Fairley.	B. E. R. Newlands.
Prof. A. G. Green.	John Pattinson.
H. Hemingway.	A. G. Perkin, F.R.S.
John Heron.	F. B. Power, Ph.D.
Prof. W. R. E. Hodgkinson, Ph.D.	Prof. H. R. Procter.
G. T. Holloway.	Sir Boverton Redwood.
E. Grant Hooper.	Walter F. Reid.
David Howard.	John Spiller.
Julius Hübner.	L. T. Thorne, Ph.D.
Charles A. Keane, D.Sc., Ph.D.	Thomas Tyrer.

Editor:

Watson Smith, 34, Upper Park Road, Haverstock Hill, N.W.

Assisted by the following Staff of Abstractors.

J. Allan	XII.	J. H. Johnston	XVIII.
E. F. Armstrong	(XVI, XVII,	A. T. Larter, B.Sc.	H, IV.
Ph.D., D.Sc.	(XVIII, XX,	A. G. Levy, B.Sc.	VIII, IX.
H. G. Bennett	XIX.	E. W. Lewis	XIII.
J. O. Braithwaite	XX.	G. W. Macdonald, M.Sc.	XXII.
J. F. Briggs	(XVI, XVII,	F. Marsden, Ph.D.	IV, V.
	XIX, XX.	C. A. Mitchell,	XII, XXII.
H. Brumwell	XIV.	B. A.	
T. F. Burton	(III, XX, XXI,	Barker North	V, XI.
B.Sc.	Patent List.	T. H. Pope,	XVI, XVII,
J. C. Cain, D.Sc.	IV, V, XX.	B.Sc.	XX, XXI.
W. H. Coleman	I, III, VII.	O. Reichertz	VII, IX, XVIII.
P. F. Crosland	V, VI.	F. Rowley	IX, X, XI.
J. T. Dunn, D.Sc.	VII, X.	Chas. Salter	(II, III, IX,
L. Eynon, B.Sc.	XVI, XVII.		XVI, XVII.
E. Feiloann, Ph.D.	IV, V.	F. Shedden	XX.
J. Wilberforce Green	XVIII,	A. Shonk	III, VII, X, XI.
	XXII.	R. L. Siau	XXI, XXII.
C. J. Guttman, B.Sc.	I, XXII.	W. P. Skertchly	(XII,
Walter C. Han-	cock, B.A.		XVIII.
	(IX.	F. Southerden, B.Sc.	IX, XX.
S. H. Higgins, M.Sc.	V.	H. H. Stephenson	VIII, IX.
J. W. Hinchley	VII, X, XI.	L. J. de Whalley, B.Sc.	XVI.
C. F. Hudson	X.	C. A. Wonham, B.Sc.	X.

Birmingham Section.

Chairman: T. Slater Price.

Committee:

F. H. Alcock.	O. F. Hudson.	R. S. Morrell.
N. Parr Booth.	E. Hunt.	H. T. Pinnock.
P. F. Frankland.	J. F. Liverseege.	E. C. Rossiter.
H. L. Heathcote.	C. A. Mander.	Harry Silvester.
A. H. Horns.	J. C. Mann.	

Hon. Local Secretary and Treasurer.

F. R. O'Shaughnessy, Tyburn, nr. Birmingham.

Canadian Section.

Chairman: Milton L. Hersey.

Vice-Chairmen:

Wallace P. Cohoe, A. McGill, W. Lash Miller.

Committee:

M. L. Allard.	Nevil N. Evans.	W. B. Tindall.
E. G. R. Ardagh.	C. F. Heebner.	T. H. Wardleworth.
C. F. Bardorf.	F. L. Langmuir.	G. J. Webster.
W. Hodgson Ellis.	A. Nieghorn.	

Hon. Treasurer: J. W. Bain, University of Toronto.

Hon. Local Secretary:

Alfred Burton, 2-16, Liberty Street, Toronto.

Liverpool Section.*Chairman:* Max Muspratt.*Vice-Chairman:* J. T. Conroy.*Committee:*

J. Campbell Brown.	W. Ramsay.	J. W. Towers.
Arthur Carey.	W. H. Roberts.	Alex. Watt.
Eustace Carey.	H. B. Stocks.	W. Collingwood
G. C. Clayton.	J. M. Taylor.	Williams.

Hon. Treasurer: W. P. Thompson.*Hon. Local Secretary:*

W. R. Hardwick, 13, Batavia Buildings, Haekins Hey, Liverpool.

New York Section.*Chairman:* Maximilian Toch.*Vice-Chairman:* C. E. McKenna.*Committee:*

L. N. Adler.	W. D. Horne.	R. W. Moore.
T. Lynton Briggs.	L. S. Kohnstamm.	T. J. Parker.
V. Coblenz.	Hugo Lieber.	F. J. Pond.
W. F. Fuerst.	E. G. Love.	Geo. C. Stone.
Bernhard C. Hesse.		

Hon. Treasurer: Frank C. R. Hemingway, 133, Front Street, New York City, U.S.A.*Hon. Local Secretary:*

H. Schweitzer, 117, Hudson Street, New York City, U.S.A.

London Section.*Chairman:* J. Lewkowitsch.*Vice-Chairman:* E. Grant Hooper.*Committee:*

A. C. Cleverman.	G. T. Holloway.	I. R. Power.
W. P. Dreyer.	D. L. Howard.	W. F. Reid.
A. Hazden.	C. A. Keene.	L. T. Florine.
H. Hemingway.	W. J. Leonard.	J. A. Voelcker.
W. R. Holman on.		

Hon. Local Secretary and Treasurer:

Julian L. Baker, Stainesbury Holt, Kingston Road, Staines.

Nottingham Section.*Chairman:* S. J. Pentecost.*Vice-Chairman:* O. Quibell.*Committee:*

L. Archbutt.	J. I. Kempson.	H. J. S. Sand.
F. J. R. Carulla.	F. Stanley Kipping.	G. J. Ward.
J. Golding.	T. H. Lloyd.	J. White.
T. F. Harvey.	J. M. C. Paton.	J. T. Wood.

Hon. Local Secretary and Treasurer:

S. R. Trotman, 1, Regent Street, Nottingham.

Manchester Section.*Chairman:* R. H. Clayton.*Vice-Chairman:* G. J. Fowler.*Committee:*

J. Allan.	J. H. Roseason.	J. F. Thorpe.
W. H. Bentley.	E. Knecht.	L. E. Miles.
W. H. Coleman.	J. H. Lester.	E. E. Wielder.
W. B. Hart.	W. Thomson.	

Hon. Local Secretary:

Julius Hubner, Ash Villa, Cheadle Hulme, Cheshire.

Scottish Section.*Chairman:* D. J. Playfair.*Vice-Chairman:* Robert Hamilton.*Committee:*

Journal and Patent Literature.

PATENT SPECIFICATIONS may be obtained by post by remitting as follows:—

English.—8d. each, to the Comptroller of the Patent Office, W. Temple Franks, Esq., Southampton Buildings, Chancery Lane, London, W.C.

United States.—1s. each, to the Secretary of the Society.

French.—1 fr. 25 c. each, to Belin et Cie., 56, Rue des Francs Bourgeois, Paris (3e.).

German.—1 mark each (with full particulars) to Kaiserlich Patentamt, Berlin, Germany.

I.—PLANT, APPARATUS, AND MACHINERY.

PATENTS.

Rotary drums; Supporting inclined.—W. Clark, London. From Fellner und Ziegler and A. B. Helbig, Frankfurt-on-Maine, Germany. Eng. Pat. 24,328, Nov. 12, 1908.

THE brackets of the rollers supporting the weight of rotary drum furnaces or kilns are mounted so as to be capable of rotation in two directions. Each bracket as a whole can rotate on its foundation (parallel to the axis of the drum) and is connected by rods with the other brackets to ensure similar angular position. Under the pressure of the drum, each roller can also move about an axis passing approximately through the point of contact of the drum and the roller. In this way the drum may be made, during continuous rotation, to take its bearing at the middle of the faces of the supporting rollers.—J. W. H.

Centrifugal machines. J. B. Allott and A. M. Philips, Nottingham. Eng. Pat. 25,435, Nov. 25, 1908.

THE basket of a centrifugal machine is provided with a door or doors in its bottom by means of which the contents may be removed. The door is hinged on the side near the axis of the machine and may be opened by means of a vertical rod having a spring catch. The parts are arranged so that the centrifugal force produced while the machine is in action tends to keep the door closed.

—J. W. H.

Separating air and other gaseous fluid from liquids; Means for.—J. Hallett, London. Eng. Pat. 27,466, Dec. 17, 1908.

THE apparatus is intended for separating air from a liquid flowing through pipes. It consists of an enlargement in the pipe, provided with a central baffle-plate to direct the gases into a casing above, in which the separated gases accumulate. The separated gases are released from this casing by means of a piston valve and float carried by a balanced lever. The whole of the mechanism is balanced so that the construction may be substantial without affecting its practical sensitiveness.—J. W. H.

Evaporating apparatus. Fawcett, Preston and Co., Ltd., and H. Shield, Liverpool. Eng. Pat. 2049, Jan. 28, 1909.

THE claim is for the provision of T-shaped flanged expansion joints in the heating belt of the evaporator.—W. H. C.

Concentration of liquids; Apparatus for the continuous.—W. Wiegand. Fr. Pat. 400,860, March 15, 1909. Under Int. Conv., March 17, 1908.

THE liquid to be concentrated is introduced through the tube, *d*, provided with a valve, *e*, and a constriction, *f*, into the chamber, *b*, of the lower vessel, *A*. It passes up the tubes, *a*, into the chamber, *c*, being heated by steam introduced through the pipe, *n*, into the space surrounding the tubes, *a*. From the chamber, *c*, the boiling liquid passes up the trumpet-shaped pipe, *g*, and is discharged in a state of spray through the narrow orifice, *t*, between the upper end of *g*, and the cover, *h*, into the separating chamber, *B*, where the vapour and liquid are separated. The vapour passes up the pipe, *i*, into the steam space of the upper vessel, *A'*, which is similar to the lower vessel, *A*, and the liquid rises up the pipe, *m*, provided with the contraction, *s*, into the chamber, *b'*. The vapour separated in the upper separating chamber, *B'*, passes through the pipe, *K*, to the condenser, the concentrated liquid being discharged through the overflow pipe, *l*. Any water

condensed in the steam space of the lower vessel, *A*, passes up the pipe, *o*, provided with a constriction, *r*, into the steam space of the upper vessel, *A'*, from which it is discharged along with any water condensed in *A'*, through the pipe, *p*, provided with the constriction, *q*, into the pipe, *K*, leading to the condenser. The constrictions mentioned serve to regulate the flow of the liquids. Several chambers may, if desired, be combined together.

—W. H. C.

Still. A. Estève. Fr. Pat. 400,839, March 4, 1909.

THE apparatus consists of a condenser and a rectifying column mounted above a tubular boiler of special construction. The latter consists of an annular vessel having a number of interior cross-tubes similar to those of a vertical boiler, which expose a large surface of the liquid to the action of the heat. The boiler and rectifying column are enclosed in an outer casing spaced away from the boiler and column in order to reduce the loss of heat by radiation. The boiler is heated by burners fed with heavy petroleum under pressure.—W. H. C.

Regenerative reverberatory furnaces. O. Friedrich. Fr. Pat. 400,924, March 17, 1909.

THE claim is for a method for reducing the time necessary for repairing the air and gas conduits between the regenerators and the furnace, which are rapidly attacked and require frequent renewal. Those portions of the conduits which are most liable to deterioration are constructed independently, so that the damaged portion may be removed and replaced bodily by spare sections, without the necessity of pulling down and rebuilding the damaged portions brick by brick.—W. H. C.

Dryer for pulverulent and other materials. A. Besson. Fr. Pat. 400,947, March 18, 1909.

THE apparatus consists of a metallic chamber through which the materials are carried on superposed endless belts and are dried by the hot gases from a furnace placed below. The hot, moisture-laden air is withdrawn from the upper part of the chamber by a fan, and passed through

a condenser chamber situated above the dryer proper, from which, after it has deposited the moisture, it is returned to the ash-pit of the furnace.—W. H. C.

Recovery of alcohol and ether lost in the air during the manufacture of powder, artificial silk, or in other processes in which alcohol and ether are employed either together or separately. Apparatus and process for the —, C. Cépelle-Fontaine. Fr. Pat. 401,182. July 9, 1909.

The air containing the vapours of alcohol or ether is withdrawn from the working place by a fan and is discharged into the base of a column, divided by horizontal partitions into sections, each of which is provided with a bubbling weir or hood and an overflow pipe. The air passes up the column and bubbles through an acid or other suitable absorbing liquid, which flows down the column from an overhead supply tank. The liquid flows from the bottom of the column through a cooler, where its temperature is reduced, to a well from which it is pumped back into the overhead tank. The column is provided with thermometers, as it is necessary for the successful recovery of the vapours to maintain the column and washing liquid at a suitably low temperature.—W. H. C.

Solvents insoluble in water; Process for separating volatile — from the dissolved substance, which is also insoluble in water, by distillation. O. Wilhelm. Ger. Pat. 213,246, April 19, 1904.

This process is applicable to the separation of the solvent from solutions of rubber, wax, etc., which are liable to decomposition by direct heat, and which are, therefore, difficult to free from the last traces of solvent. It is only suitable for those substances which are insoluble in water and not volatile in steam. The solution is poured on the surface of water, when it can be distilled by heating the water, the last traces of solvent being readily removed.—T. F. B.

Reaction between a liquid and a gas; Apparatus for ensuring by intimate contact —. C. Boudon. Fr. Pat. 401,202, March 25, 1909.

THE claim is for the method of packing a tower shown in the figures: Fig. 1, being an elevation partly sectional;

FIG. 1.

FIG. 2.

and Fig. 2, a sectional plan of the apparatus, showing the relative positions of four superposed rows of the packing material.—W. H. C.

Crystallisation vessels; Special floor for —. H. Mecher. Ger. Pat. 212,589, Aug. 11, 1908.

THE floor of the crystallisation vessel is provided with a series of radial or tangential guide-plates arranged one over the other in a manner similar to the folds of a fan. The solution is circulated in the vessel by one of the usual methods, and the guide-plates cause the motion to be horizontal, or nearly so, over the floor of the vessel.—A. S.

II.—FUEL, GAS, AND LIGHT.

Refractory metals from their chlorides; Preparation at high temperatures of some —. [Metallised filaments for electric lamps.] J. N. Pring and W. Fielding. Chem. Soc. Trans., 1909, 95, 1497—1506.

ATTEMPTS have been made to prepare electric lamp filaments of carbon coated with a refractory metal by "flashing" carbon filaments (heating them by means of a current) in an atmosphere of the chloride of the refractory metal alone or mixed with hydrogen, etc. The authors' experiments were made with a view to determine the conditions necessary for causing the separation of tungsten, molybdenum, chromium, silicon, and boron from the respective chlorides, by means of a heated carbon rod; to study the extent to which the elements react with the carbon at different temperatures; and to ascertain the photometric properties of the coated rods. The carbon rods used were 5 mm. in diam. and 7—9 cm. long. With boron trichloride and excess of hydrogen, at atmospheric pressure, a slight non-adherent deposit of boron was obtained at 1500° C. At 1750° C. a smooth skin deposit of boron carbide was produced, which at 1950° C. was more adherent and assumed a nodular form, whilst at 2150° C. large non-adherent crystals were observed. At 2200° C. a sooty deposit of the carbide and of free boron was produced on the bulb in which the carbon rod was mounted. Above 2000° C. boron appears to exert a catalytic effect in converting carbon into graphite. With silicon tetrachloride alone, no considerable deposit could be obtained. In presence of excess of hydrogen, a skin deposit of silicon was obtained at 1700° C., and crystals of free silicon at higher temperatures; at 1925° C. the deposit consisted wholly of silicon carbide. With benzene vapour in place of, or mixed with, the hydrogen, deposits of silicon carbide mixed with carbon were obtained. With tungsten hexachloride vapour alone, at a pressure of 10 mm., deposition of the metal began at 1000° C. At all temperatures tried (1200° C. to 2050° C.), the deposits were of a silver-white colour, adherent, and

smooth. Between 1000° and 1500° C., the deposit consisted of the metal, being comparatively soft and unable to mark glass; at higher temperatures the deposit consisted of carbide, scratching glass easily. With molybdenum tetrachloride and pentachloride under similar conditions to those employed with tungsten hexachloride, deposits of metallic molybdenum were obtained at temperatures below 1330° C., and of carbide at higher temperatures. When the deposition of tungsten and molybdenum was effected in presence of 1–2 ccs. of water vapour, the bulb being otherwise vacuous, the deposits were always free from carbon, but were less adherent than those obtained in absence of water vapour. No satisfactory deposits could be obtained from chromium oxychloride vapour.

The photometric efficiency of the coated rods was measured approximately in comparison with that of a carbon rod of the same size. The carbon rods were 5.5 cm. long and 4 mm. diam., and the deposits were in most cases 0.25 mm. thick (0.75 mm. in the case of silicon). The measurements were made with a photometer of the Lummer-Brodheim type, and the results were expressed in terms of the standardised lamp.

	Carbon rod.	Tungsten deposit.	Molybdenum deposit.	Boron deposit.
Luminous intensity with 332 watts, temp. 1600° C.....	1.01	3.00	2.97	—
Luminous intensity, with 465 watts, temp. 1775° C.....	3.40	6.06	6.27	1.16

With a rod coated with silicon carbide (diam. 5.5 mm.) the value was as low as 0.91. With the boron and silicon deposits, the luminosity was not sufficiently high for measurement with the lower amount of power.—A. T. L.

PATENTS.

Coking process. L. L. Summers, Chicago, Ill. U.S. Pat. 935,175, Sept. 28, 1909.

THE fuel is passed continuously through a horizontal retort and the gases distilled from the freshly charged fuel are caused to pass transversely through the hotter portions of the fuel column.—A. T. L.

Compression of gas or air for lighting or heating purposes; Apparatus for the —. E. Fletcher, Tottenham. Eng. Pat. 26,719, Dec. 9, 1908.

THE apparatus consists of a double-acting, reciprocating air-pump without valves. In the middle of the cylinder two ports are arranged: one communicates with the low-pressure gas supply and the other with the reservoir of compressed gas. The piston is longer than the stroke of the pump and has two sets of ports, which at the ends of the stroke coincide with those in the cylinder walls, so that the compressed gas is released from one end of the cylinder and flows to the reservoir, and the gas from the supply enters the other end of the cylinder and destroys the partial vacuum produced there.—J. W. H.

Gas-generator. J. Darling, Chicora, Pa., Assignor to The Smokeless Heat and Power Co., Cleveland, Ohio. U.S. Pat. 933,828, Sept. 14, 1909.

THE claims are for a gas-generator comprising vertical furnace walls, with two series of horizontal retorts arranged one above the other and extending across the furnace chamber, the lower retorts being connected by pipes to the retorts above them. The ends of the retorts are rectangular and the vertical sides are provided with ribs which abut against the ribs of the adjacent retorts, so as to space the retorts apart and permit of a vertical joint being made between them with mortar.—A. T. L.

Gas-producer. H. I. Lea, Pittsburg, Pa., Assignor to The Westinghouse Machine Co. U.S. Pat. 934,446, Sept. 21, 1909.

THE producer, which works with a down-draught, comprises a truncated conical producer chamber arranged above an ash chamber of inverted truncated conical form. A ring of gas outlet ports is formed at the widest part of the producer, leading to an annular gas-collecting chamber. The ash-pit is water-sealed.—A. T. L.

Water-gas; Process of making —. C. E. White, Philadelphia, Pa. U.S. Pat. 935,344, Sept. 28, 1909.

A COLUMN of refractory material is heated in an electric furnace, and steam or steam and hydrocarbons, is passed through the heated mass. The heating current passes transversely through the column between a series of electrodes arranged at the two sides. The column is heated to different temperatures at different points, by varying the current density, and the steam is passed through the whole column while the hydrocarbon is passed through only a part of it.—A. T. L.

Gas-generating apparatus. J. H. Stringham, Jersey City, N.J., Assignor to The Westinghouse Machine Co. U.S. Pat. 935,429, Sept. 28, 1909.

THE invention relates to a gas producer having a water-jacketed casing forming a steam generator. The jacket can be heated independently of the producer fire by means of a gas burner beneath it, the combustion products from this burner passing up through vertical heating tubes in the jacket. The blast-pipe for the producer chamber is perforated and is supplied with air from a number of valved branch pipes, so that the blast to different portions of the pipe can be independently controlled.—A. T. L.

Tar and other substances from blast furnace, producer and other gases; Purification of and recovery of —. W. C. Neilson, Coatbridge, Lanark. Eng. Pat. 28,462, Dec. 31, 1908.

PRODUCER or other gases are treated with vaporised cresote oil or other solvent for tar, before being passed through tar-trapping devices. Under ordinary circumstances, in purifying producer or furnace gases at 45° C., 1 part of oil to 7000 parts of gas (by weight) will reduce the viscosity of the tar sufficiently.—J. W. H.

Gas-washing apparatus. O. H. Ensign, Madison, Wis. U.S. Pat. 933,966, Sept. 14, 1909.

THE apparatus comprises a cylindrical chamber containing a bell or holder with perforated walls sealed at the lower edge. The gas is admitted to the interior of the bell and is cleaned by passing through the walls. The bell is continuously rotated, and washed by a water-spray playing on its outer surface.—A. T. L.

Natural gas; Apparatus for recovering light oils from —. J. L. Gray, Elizabeth, N.J. U.S. Pat. 933,976, Sept. 14, 1909.

THE apparatus comprises a compressor which forces the gas through a separator, a condenser, a second separator, and finally through a relief valve which maintains a steady pressure within the system. The oil collected in the second separator passes to a closed trap, having its discharge valve controlled by the liquid, and the upper part of this trap is connected to the gas main between the separator and the relief valve.—A. T. L.

Gas-scrubbing apparatus. J. J. Nix, Los Angeles, Cal. U.S. Pat. 934,205, Sept. 14, 1909.

THE apparatus consists of an annular vertical cylindrical casing, divided by radial partitions into a number of compartments. Gas is admitted to one of the compartments through its outer wall and is led downwards through a pipe bent at right-angles and open at its lower end. This pipe is fitted with a water-spray pipe at the top of the vertical limb. The gas passes from each compartment to the next by a similar pipe bent at right-angles and fitted with a sprayer, the last compartment being connected to the gas outlet. Each compartment

is fitted with a water overflow pipe which maintains the water-level slightly below the open ends of the bent pipes, but a second overflow at a higher level is fitted to the inlet compartment so that the inlet pipe may be sealed when desired.—A. T. L.

Gas purifier. H. I. Lea, Pittsburg, Pa., Assignor to The Westinghouse Machine Co. U.S. Pat. 934,448, Sept. 21, 1909.

THE apparatus comprises a wet scrubber, a water-seal box, and a drying chamber, all arranged within a single casing. The gas enters through a down-pipe which extends below the water level in the water-seal box at the base of the apparatus, then passes up through a scrubbing column against a counter-current of water. The gas is then led down through a water-sealed pipe and finally passes up through a drying column to the gas outlet.

—A. T. L.

Gas-purifying apparatus. H. I. Lea, Pittsburg, Pa., Assignor to The Westinghouse Machine Co. U.S. Pat. 934,679, Sept. 21, 1909.

THE apparatus comprises a dust-collecting chamber of inverted conical form arranged beneath a multitubular boiler having vertical heating tubes, the boiler being surmounted by a gas-collecting chamber provided with a gas-outlet and also with a stack-pipe. The dust-collecting chamber is fitted with a fuel grate beneath the boiler, and an air inlet is provided beneath the grate. The gas-inlet to the dust-collecting chamber is provided with a vertical baffle-plate to direct the gas downwards.

—A. T. L.

Incandescence lamps; Manufacture of filaments for —. Cie. Franç. de la Lampe Canello. First Addition, dated July 9, 1908, to Fr. Pat. 361,602, July 3, 1905 (this J., 1906, 976).

THE process described in the principal patent is simplified by incorporating a solution of cellulose with the solution or mixture of substances from which the filament is to be formed, and then forming threads from this mixture, instead of impregnating a cotton or other thread. An oxygen or sulphur compound of osmium, tungsten or molybdenum is added to the mixture of rare earths, and the threads formed as described, after being dried and heated in a reducing gas, are decarbonised by the passage of a current, with the formation of carbon monoxide, dioxide or bisulphide. The filaments are finished by heating them in hydrogen.—A. T. L.

Incandescent electric lamps; Manufacture of filaments for —. Soc. Franç. d'Incandescence par le Gaz (Système Auer). Fr. Pat. 401,307, July 18, 1908.

FILAMENTS formed from a mixture of oxides of metals or of metalloids with lampblack and a binding agent, are heated to redness in a reducing atmosphere to render them conducting, and are then decarbonised by heating electrically in gases containing oxygen or sulphur to combine with the carbon. The filaments are then "metallised" by heating to a high temperature in an atmosphere containing hydrogen and ammonia. The ammonia may be formed in the vessel in which the "metallising" process is carried out by passing sparks through a mixture of nitrogen and hydrogen in this vessel, or by decomposing an ammonium salt therein. The decarbonising and "metallising" processes may be carried out simultaneously by mixing the decarbonising gases with the hydrogen and ammonia. When the filaments are of vanadium, titanium or other metals which combine with nitrogen, the small quantity of air not removed from the lamp bulbs by the vacuum pump is absorbed by the filament itself, or by an auxiliary filament used for this purpose, or by charcoal, or a metal such as calcium or magnesium, thus leaving in the bulbs only gases of the argon group.—A. T. L.

Coke ovens; Regenerative —. Act. Ges. f. Kohlen-destillation and L. Holbeck, Gelsenkirchen-Bulmke, Westphalia. Eng. Pat. 19,264, Sept. 14, 1908.

SEE Fr. Pat. 394,077 of 1908; this J., 1909, 237.—T. F. B.

Gas-holders; Method of protecting the iron walls of — from the destructive influence of the cyanogen compounds entering the water of the seal from the gas. O. Kaysser, Dortmund, Germany. Eng. Pat. 18,672, Sept. 5, 1908.

SEE Fr. Pat. 393,661 of 1908; this J., 1909, 132.—T. F. B.

Gas and air; Process for the manufacture of a mixture of — for illuminating purposes. F. W. Wolff, Assignor to Selas-Ges. m.b.H., Berlin. U.S. Pat. 935,444, Sept. 28, 1909.

SEE Eng. Pat. 25,596 of 1905; this J., 1907, 41.—T. F. B.

Liquids and gases; Apparatus for effecting intimate contact of —. [Gas washers, &c.]. S. Hersey, London, and E. W. Blake, Croydon, Assignors to Kirkham, Hulett, and Chandler, Ltd., London. U.S. Pat. 935,501, Sept. 28, 1909.

SEE Eng. Pat. 28,387 of 1907; this J., 1909, 83.—T. F. B.

Filling and emptying gas-burettes. Ger. Pat. 212,338. See XXIII. Apparatus.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

Aniline; Action of potassium hydroxide on —. A. Bacoescu. Ber., 1909, 42, 2938—2940.

WHEN aniline is mixed with 12 parts of powdered potassium hydroxide and kept for 3 hours, most of the aniline is converted into a mixture of azobenzene and *o*-hydroxyazobenzene. Azobenzene itself when heated on the water-bath with potassium hydroxide yields traces of *o*-hydroxyazobenzene. Hydrazobenzene similarly gives azobenzene and traces of *o*-hydroxyazobenzene. The formation of *o*-hydroxyazobenzene in these reactions is probably due to the direct action of the alkali on azobenzene, but the other transformations are probably effected through the oxygen of the air.—J. C. C.

Paraffin crystals; Acicular — and their importance for the Scottish sweating process. E. Pyhälä. Seventh Int. Congr. Appl. Chem., London, 1909. Petroleum, 1909, 4, 1392—1394.

ACCORDING to the author, the acicular form of crystallised paraffin wax yields far better results than the tabular or foliaceous type of crystals, when the cakes are refined by the dry sweating process in the Henderson apparatus. The crystals, which are 15—20 mm. long and 0.5—1 mm. thick, spring from the upper and lower surfaces of the cake; and on the application of heat, the solidified oils located between the crystals, melt and drain away readily. On the other hand, the tabular crystals retard the escape of the melted oil, and delay the extraction, sometimes for several weeks, the residual mass being still more or less impure.—C. S.

Toxicity of aniline derivatives. Hildebrandt. See XX.

PATENTS.

Coal; Apparatus for the destructive distillation of —. T. Parker, Wednesfield. Eng. Pat. 14,167, July 3, 1908.

THE apparatus, which is shown in transverse section in the figure, comprises two series of batteries, *a*, of vertical retorts extending throughout its length, with chambers, *b*, for the heating gases between successive batteries of retorts. Producer gas is distributed from two longitudinal gas-chambers, *c*, by means of conduits, *e*, provided with shut-off valves, *f*, leading to mixing chambers, *g*, beneath the chambers, *b*. Air is admitted to the mixing chambers by valves, *j*, consisting of slotted pipes which may project to any desired extent into the mixing chamber, so as to expose more or less of the length of the slots. The combustion gases pass through the open brickwork of the walls of the chambers, *b*, and circulate around the retorts, passing finally to the chimney. The coke from the retorts is allowed to fall on to the inclined

walls, *l*, of a central discharge chamber, *k*, so as to be broken up before reaching the conveyor, *z*. The mechanism for operating the doors at the lower ends of the retorts is carried within the chamber, *k*, and is arranged to be operated by shafts, *o*, from the two sides of the setting.

—A. T. L.

Mineral oils ; Treatment of — J. J. Hood and A. G. Salamon, London, Eng. Pats. 16,617, Aug. 6, 1908, and 24,209, Nov. 11, 1908.

DARK-COLOURED oils are treated with or filtered through finely-divided alumina, magnesia, bauxite, or magnesite in order to decolorise them. The filtering material is previously ignited at a temperature below redness and after use can be regenerated by being washed with petroleum spirit and again ignited. Certain kinds of magnesite and bauxite are first treated with acids or alkalis before use. Thick, viscous oils are diluted with petroleum spirit of low boiling point, and after treatment the light petroleum is distilled off.—W. H. C.

Sulphuric acid and oils ; Process for the recovery of — from waste acid. G. Stolzenwald, Ger. Pat. 212,000, Aug. 6, 1907.

THE waste acid, *e.g.*, that from the refining of petroleum oils, is passed upwards through a series of vertical retort-tubes, wider in their lower than in their upper parts, and is heated gradually in these retorts to a temperature at which resinous and tarry matters are carbonised. In the lower cooler parts of the retorts, the oils, *etc.*, are volatilised, whilst in the upper, strongly heated portions, the tar, *etc.*, is decomposed, together with a small quantity of the sulphuric acid. The vapours, together with some entrained charcoal, leave the retorts through a discharge pipe at the top. From this discharge pipe, a pipe passes vertically downwards into a vessel, where it dips into a liquid seal. The condensed sulphuric acid and the charcoal pass down this pipe, and are separated by settling.

The oil vapours and any sulphur dioxide are led to a condenser, where the oils condense, whilst the sulphur dioxide may be subsequently converted into sulphuric acid.—A. S.

Recovery of useful constituents of sewage. Eng. Pat. 18,199. See XVIII.B.

Distillation of wood, with direct utilisation of the charcoal for metallurgical purposes. Fr. Pat. 401,226. See X.

IV.—COLOURING MATTERS AND DYESTUFFS.

Amines ; Diazotisation of weakly basic, sparingly soluble, primary —, and some reactions connected therewith. O. N. Witt. Ber., 1909, 42, 2953—2961.

THE diazotisation of weakly basic amines, such as dinitraniline or 2:6-dichloro-*p*-nitraniline, can be very readily effected when the base is dissolved in concentrated nitric acid (sp. gr. 1.48). The nitrous acid is produced from the nitric acid by adding the calculated amount of potassium pyrosulphite (metabisulphite). The process is best carried out by grinding together the base and pyrosulphite and adding the mixture gradually to the cooled nitric acid, the quantity of which may be 2—3 times that of the base employed. The resulting diazo-solution is very stable ; when required for use it is best diluted with powdered ice. The diazo-compound of dichloronitraniline combines with β -naphthol in strongly acid solution, yielding an insoluble scarlet red azo-compound. Dichloronitraniline itself, when treated with concentrated nitric acid, is converted slowly into dichloro-*p*-nitrophenylamine, which yields readily soluble metallic salts, except in the case of the thorium salt, which is insoluble ; it is suggested that this latter salt might be used for the analytical estimation of thorium.—J. C. C.

Amino- and hydroxy-compounds ; Action of sulphites on aromatic —. 7th Communication. Application of the sulphite reaction to some ana-(1.5)-derivatives of naphthalene. H. T. Bucherer and A. Uhlmann. J. prakt. Chem., 1909, 80, 201—241.

1:5-NAPHTHYLENEDIAMINE-2-SULPHONIC acid is prepared by heating purified 1:5-naphthylenediamine sulphate with 6 parts of fuming sulphuric acid containing 5 per cent. of sulphur trioxide for 1½ hours at 100°—110° C. The mixture is cooled, mixed with 1 part of fuming acid containing 25 per cent. of sulphur trioxide and again warmed. The sulphonic acid separates on pouring the mass into water. On boiling this acid for 12 hours with sodium bisulphite solution (36° B.), treating the product first with sodium hydroxide and then with hydrochloric acid, 1:5-aminonaphthol-2-sulphonic acid is obtained. 5-Acetylamino-1-naphthylamine-8-sulphonic acid, prepared by reducing Nietzki and Zübelen's nitroacetylnaphthionic acid with zinc dust and hydrochloric acid at a temperature not exceeding 30° C., on saponification and treatment of the resulting diamino-acid with sodium bisulphite, yields 1:5-aminonaphthol-8-sulphonic acid. The constitution of this acid is confirmed by its yielding 1:5-aminonaphthol when heated with 20 per cent. hydrochloric acid. With tetrazotised benzidine in alkaline solution it yields a dyestuff giving blue violet shades on cotton which, when diazotised and developed on the fibre with β -naphthol, become dirty reddish-violet. When combined with the same tetrazo-compound in acid solution, a dyestuff is obtained which gives deep blue shades on cotton ; on diazotisation and development with β -naphthol, clear brown shades are produced. When 5-acetylamino-1-naphthylamine-8-sulphonic acid is heated on the water-bath for 20 hours with sodium bisulphite solution (38° B.), 1:5-aminonaphthol-4-sulphonic acid is produced, which is separated from the diamino-acid and the isomeric acid by fractional precipitation. When further treated with bisulphite the acid yields the corresponding dihydroxynaphthalenesulphonic acid. This, when heated in a sealed tube with ammonia, yields first the aminonaphthol-

sulphonic acid just described and finally the diamino-acid. By sulphonating 1:5-dihydroxynaphthalene it seems probable that a mixture of 1:5-dihydroxynaphthalene-2- and -5-sulphonic acids are produced. When 1:5-amino-naphthol-7-sulphonic acid ("M" acid) is treated with bisulphite, it is converted into 1:5-dihydroxynaphthalene-7-sulphonic acid.—J. C. C.

Aniline Black; Constitution of —. H. T. Bucherer. Ber., 1909, 42, 2931–2933.

THE author cannot accept Willstätter and Dorogi's formula (this J., 1909, 635) for Aniline Black and points out that an indamine formula for Emeraldine, the red imine and Aniline Black which are all very stable towards acids, is not reconcilable with the fact that indamines are extremely susceptible to the action of acids. The azine constitution is at least equally probable in the case of the dyestuffs of the Aniline Black group.—J. C. C.

o-Azothioanisol and o-thiodianisidine. K. Brand. Ber., 1909, 42, 3463–3468.

THE compounds mentioned in the title have been prepared by the following series of reactions. *o*-Nitrothiophenol, $\text{SH}\cdot\text{C}_6\text{H}_4\cdot\text{NO}_2$, is obtained by boiling an alcoholic solution of *o*-dinitrodiphenyl disulphide with a mixture of sodium hydrosulphide and hydroxide or a suitable amount of sodium sulphide, disulphide, or polysulphide. The solution of the sodium salt of *o*-nitrothiophenol is heated with potassium methyl sulphate for some hours on the water-bath or, better, is diluted with water and treated with dimethyl sulphate. A quantitative yield of *o*-nitrothioanisol, m.p. 85° – 87°C , is obtained. On electrolytic reduction by Elbs's method, this is converted into *o*-azothioanisol, m.p. 156 – 158°C , which can be reduced to *o*-hydrazothioanisol, m.p. 104°C , by means of sodium or ammonium hydrosulphide. The latter is more conveniently prepared, however, from *o*-nitrothioanisol by reduction with zinc dust and sodium hydroxide. On treatment with hydrochloric acid for several hours in the cold, this is transformed into *o*-thiodianisidine, m.p. 110 – 112°C , the tetrazo-compound of which gives with salicylic acid an orange yellow, and with H-acid a blue dyestuff both of which dye cotton direct. The diacetyl compound melts at 245° – 247°C .—J. C. C.

PATENTS.

1:8-Diaminonaphthalen-4-sulphonic acid; Manufacture of —. P. A. Newton, London. From Farbenfabr. vorm. F. Bayer und Co., Elberfeld, Germany. Eng. Pat. 6831, March 22, 1909.

1:8-NAPHTHYLENEDIAMINE acid sulphate, or a mixture of sulphuric acid and 1:8-naphthylenediamine capable of forming the acid sulphate, is heated, preferably *in vacuo*, to temperatures above 100°C (e.g., to 155°C for about 10 hours); the product is dissolved in dilute sodium carbonate solution, filtered, and the filtrate acidified, when 1:8-naphthylenediamine-4-sulphonic acid separates out.—T. F. B.

Azo dyestuffs. L. Hesse, O. Günther, and A. Zart. Assignors to Farbenfabr. vorm. F. Bayer und Co., Elberfeld, Germany. U.S. Pats. 933,446, 933,447, 933,448, and 933,562, Sept. 7, 1909.

(1). CLAIM is made for the azo dyestuff prepared by combining diazotised aniline-*o*-sulphonic acid with cresidine, diazotising the resulting aminoazo-compound and combining it with 5-hydroxy-1:2-phenylnaphthiminazole-7-sulphonic acid. The sodium salt is a dark powder giving a blue solution with concentrated sulphuric acid and dyeing cotton in blue shades. (2). An azo dyestuff is prepared by combining diazotised 1-naphthylamine-2:4-disulphonic acid with *p*-xylydine, diazotising the resulting aminoazo-compound and combining it with 2-phenylamino-5-naphthol-7-sulphonic acid. The sodium salt is a dark powder giving a blue-green solution with concentrated sulphuric acid and dyeing cotton in violet shades. (3). Diazotised aniline-*o*-sulphonic acid is combined with *p*-xylydine, the resulting aminoazo-compound is diazotised and combined with 2-amino-5-naphthol-1:

7-disulphonic acid. The sodium salt of the product is a dark green powder giving a greenish-blue solution with concentrated sulphuric acid and dyeing cotton in bluish-red shades. (4). An azo dyestuff is prepared by combining diazotised *m*-xylydine-*o*-sulphonic acid with *p*-xylydine, diazotising the resulting aminoazo-compound and combining it with 2-phenylamino-5-naphthol-7-sulphonic acid. The product in the form of the sodium salt is a dark green powder giving a blue solution with concentrated sulphuric acid and dyeing cotton in reddish-violet shades.—J. C. C.

Anthracene series; Process for preparing grey vat dyestuffs of the —. Farbenfabr. vorm. F. Bayer und Co. Ger. Pat. 213,501, Oct. 1, 1908.

α -*ANTHRACENES* are nitrated and the nitro-compounds reduced; the resulting compounds dye cotton fast grey shades from the vat.—T. F. B.

Sulphur [sulphide] dyestuffs; Brown and olive —. K. Gly, Berlin, and P. Dieterle, Lyons, Assignors to Act.-Ges. f. Anilinfabr., Berlin. U.S. Pats. 934,302 and 931,303, Sept. 14, 1909.

WHEN *o*- or *p*-aminophenol is heated with *m*-toluylenediamine and sulphur, sulphide dyestuffs are obtained which dye cotton fast brown and olive shades respectively from alkali sulphide solutions, without mordants. The dyestuffs from one mol. of *o*-aminophenol and two of *m*-toluylenediamine, and from two mols. of *p*-aminophenol and one of *m*-toluylenediamine are described.—T. F. B.

Azo dyestuff dyeing chromed wool; Process for the production of an —. Act.-Ges. f. Anilinfabr. Fr. Pat. 401,092, March 22, 1909.

o-CHLORO-*p*-NITRANILINE is diazotised and combined with salicylic acid in alkaline solution. The resulting azo dyestuff gives fast brick-red shades on chromed wool.—J. C. C.

Monoazo dyestuffs; Process for the production of yellow —. Act.-Ges. f. Anilinfabr. Fr. Pat. 401,133, March 23, 1909.

THE disulphonic acid of *p*- or *o*-toluidine is diazotised and combined in alkaline solution with phenylmethylpyrazolone. The azo dyestuff obtained gives clear yellow shades on wool, which are very fast to light.—J. C. C.

Dyestuffs; Manufacture of new —. Farbwerke vorm. Meister, Lucius, und Brüning. Second Addition, dated Feb. 11, 1909, to Fr. Pat. 400,590, Feb. 11, 1909. Under Int. Conv., Nov. 6, 1908. (See Eng. Pat. 3758, this J., 1909, 975, and Ger. Pat. 208,968, this J., 1909, 517.)

INSTEAD of the diamines mentioned in the principal patent and the first addition, their sulphonic acids may advantageously be employed. An example is given describing the combination of diazotised *p*-nitrobenzoyl-*p*-phenylene-diaminesulphonic acid with *p*-nitrobenzoyl-2:5:7-aminonaphtholsulphonic acid in alkaline solution. The resulting dyestuff gives bluish-red shades on cotton which are unchanged by diazotisation and development with β -naphthol on the fibre.—J. C. C.

3-Oxy-(1)-thionaphthene; Process for preparing halogen-substituted —. Badische Anilin und Soda Fabrik. Ger. Pat. 212,942, Oct. 23, 1906.

3-OXY-(1)-THIONAPHTHENE and its homologues or derivatives are converted into halogen-substitution products by treatment with chlorine or bromine or substances which produce chlorine or bromine (excepting alkali hypochlorites or hypobromites). Mono- or di-halogen derivatives can be produced, the halogen being attached to the nucleus containing sulphur.—T. F. B.

Dyestuffs soluble in fats, oils, and resins; Process for preparing —. Chem. Fabr. Flörsheim Dr. H. Noerdlinger. Ger. Pat. 213,172, Nov. 29, 1908. Addition to Ger. Pat. 198,278, Jan. 6, 1907.

THE dyestuffs soluble in fats, oils, etc., prepared according to the original patent (this J., 1908, 801), are rendered much more intense and brilliant by mixing them with basic dyestuffs soluble in fats. These basic dyestuffs may be added to the other dyestuffs at a suitable stage of the process, or both dyestuffs may be rendered fat-soluble by one process. Also the alkali salts of alizarin may be precipitated by means of basic dyestuffs, and the resulting product mixed or melted with the alkaline-earth, earth, or heavy metal salts of fatty or resin acids, with or without addition of free fatty or resin acid.

—T. F. B.

Azoxy dyestuffs dyeing cotton direct; Process for preparing —. L. Cassella and Co. Ger. Pat. 213,278, March 12, 1908.

DIAZOTISED *p*-nitraniline or one of its derivatives is combined in acid solution with 2,5-aminonaphthol-7-sulphonic acid; on reducing this azo dyestuff by means of alkaline reducing agents, direct cotton azoxy dyestuffs are obtained, which, when developed on the fibre, produce very fast, deep red shades; in this respect they differ from the dyestuffs obtained by performing the combination in alkaline solution, the shades of these not being improved by development.—T. F. B.

Vat dyestuffs; Process for preparing halogenated red —. Ges. f. Chem. Ind. in Basel. Ger. Pat. 213,504, June 5, 1908. Addition to Ger. Pat. 196,349, April 27, 1907. (See this J., 1908, 557.)

THE condensation product of acenaphthenequinone and 3-oxy-(1)-thionaphthene is treated with halogens or substances developing halogens, at the ordinary temperature, in presence of concentrated sulphuric acid. (See also Ger. Pat. 198,510; this J., 1908, 801.)—T. F. B.

Vat dyestuffs; Process for preparing halogenated —. Ges. f. Chem. Ind. in Basel. Ger. Pat. 213,505, May 12, 1908.

HALOGEN-SUBSTITUTED isatin derivatives of the naphthalene series are condensed with 3-oxy-(1)-thionaphthene and its derivatives. These products form vats from which cotton is dyed various shades of brown-violet, violet-grey, grey, and violet-black.—T. F. B.

Dyestuffs containing sulphur; Preparation of leuco-compounds of —. Kalle and Co. A.-G. Ger. Pat. 213,714, March 29, 1908.

WHEN diindole is condensed with 3-oxy-(1)-thionaphthene or its 2-carboxylic acid or another of its benzene-substitution products, preferably in presence of an alkali carbonate, leuco compounds of indigo analogues containing sulphur are produced. These compounds are soluble in alkali hydroxides to yellow solutions, from which red dyestuffs are precipitated in contact with air, and which serve for the production of red dyeings on fibres.—T. F. B.

Vat dyestuffs of the anthracene series; Manufacture of —. O. Imray, London. From Farbwerke vorm. Meister, Lucius, und Brüning, Höchst on Maine, Germany. Eng. Pat. 25,551, Nov. 26, 1908.

SEE Ger. Pat. 208,969 of 1908; this J., 1909, 650.—T. F. B.

Azo dyestuffs. J. Jansen and W. Neelmeier, Leverkusen. Assignors to Farbenfabr. vorm. F. Bayer und Co., Elberfeld, Germany. U.S. Pats. 933,841 and 933,842, Sept. 14, 1909.

SEE Ger. Pat. 210,597 and Fr. Pat. 396,381 of 1908; this J., 1909, 698 and 595.—T. F. B.

Vat [anthracene] dyestuff. J. Démet, Assignor to Farbenfabr. vorm. F. Bayer und Co., Elberfeld, Germany. U.S. Pat. 935,590, Sept. 28, 1909.

SEE Fr. Pat. 400,653 of 1909; this J., 1909, 1029.—T. F. B.

Pyrazolone dyes and process of making them. P. Julius and E. Fussenegger, Assignors to Badische Anilin und Soda Fabrik, Ludwigshafen on Rhine, Germany. U.S. Pat. 935,370, Sept. 28, 1909.

SEE Fr. Pat. 398,602 of 1909; this J., 1909, 832.—T. F. B.

Izo dyestuff. P. Julius and E. Fussenegger, Assignors to Badische Anilin und Soda Fabrik, Ludwigshafen on Rhine, Germany. U.S. Pat. 935,371, Sept. 28, 1909.

SEE Fr. Pat. 398,602 of 1909; this J., 1909, 832.—T. F. B.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

Silks; Proximate composition [and constitution] of various —. I. Monoamino acids from Niët ngô tsâm (China) silk. E. Abderhalden and G. A. Brossa. II. Monoamino acids from Indian tussah silk. E. Abderhalden and W. Spack. VII. Monoamino acids from the gum of Canton silk. E. Abderhalden and Worms. Z. physiol. Chem., 1909, 62, 129–132, 142–144.

THE authors have examined the products of hydrolysis from the cocoons of Niët ngô tsâm silk, and obtained a residue of melanine products equal to 1 per cent. The determination of tyrosine and the remaining monoamino acids was carried out in the usual way, and the yields obtained from 100 grms. of dry ash-free substance, were: glycocoll, 24 grms.; alanine, 18.5 grms.; tyrosine, 7.8 grms.; with small proportions of glutamic acid, aspartic acid, leucine, serine, proline, and phenylalanine. From Indian tussah silk an average yield of gum equal to 16 per cent. was obtained. The residue left by hydrolysis of the degummed silk was 16 per cent., which was reduced to 6 per cent. by a more drastic treatment. The yield of ultimate products calculated per 100 grms. of dry ash-free substance was: glycocoll, 9.5 grms.; alanine, 24 grms.; the remaining amino-acids being similar to above. The gum obtained from Canton silk gave by hydrolysis with (1), 25 per cent. sulphuric acid, (2) fuming hydrochloric acid, a residue equal to 1 per cent. In the determination of the ultimate products, it was found essential to have a good vacuum (0.1 to 0.2 mm.) for distilling the esters. By this means a fraction containing aspartic and glutamic acids was obtained. The results obtained show clearly that the gum is quite different in composition from silk fibroin or gelatin.—W. N. B.

Mordanting of wool with iron salts. R. Möhlau. Ver. Deutscher Chemiker, Sept., 1909. Chem.-Zeit., 1909, 33, 1020.

WHEN wool which has been mordanted with iron salts is exposed to light, it assumes a grey or brownish-yellow tone. A process of oxidation apparently takes place, which, however, is dependent upon the presence of light, since in an atmosphere of oxygen or ozone, and in the dark, no change occurs. The mordanted wool becomes yellow upon placing it in a slightly alkaline solution of hydrogen peroxide, indicating that the iron is oxidised from the ferro- to the ferro-ferri form. The shades obtained upon this "oxidised" mordant are richer and darker than those with the original one.—F. M.

Mordants on wool; Fixation of "Schwefel" —. R. Möhlau. Ver. Deutscher Chemiker, Sept., 1909. Chem.-Zeit., 1909, 33, 1020.

SAMPLES of wool were mordanted with salts of the following nineteen metals: cerium, thorium, zirconium, ytterbium, beryllium, aluminium, nickel, cobalt, uranium, chromium, copper, zinc, cadmium, manganese, antimony, lead, tin, thallium, and iron. Solutions of the sulphates were employed, as preliminary trials showed that from such solutions the oxide of the metal was generally absorbed by the wool. The mordanting baths were maintained at constant volume and contained (1), 5 per cent. and

alkali. The materials to be bleached remain in this peroxide-soap bath for about 12 hours and are then squeezed and rinsed.—F. M.

Mercerising under tension; Machine for —. P. Hahn. Fr. Pat. 401,004, Mar. 12, 1909.

THE pieces pass between rollers to which a heavy pressure is applied, and then into the caustic liquor. After impregnation, longitudinal shrinkage is prevented by passing the pieces between a series of squeezing rollers (the peripheral speed of each pair of which is slightly greater than that of the preceding pair) and lateral shrinkage is avoided by interposing a number of screw-threaded expanding rollers. The squeezing bowls and expanding rollers are supplied with toothed wheels, which gear one into the other and thus transmit the power from a main cog-wheel.—F. M.

Dyeing machine for wool in the form of sliver, hanks, or on bobbins. H. Maly. Fr. Pat. 401,290, Mar. 27, 1909.

THE machine comprises a vessel to contain the dye-liquors and a dye-vat, connected together by pipes supplied with three-way valves, and a rotary pump and steam injector. The material to be dyed is arranged on perforated tubes, fitting into hollow discs which are supported upon the perforated, hollow central spindle of the dye-vat. The dye-liquor is forced, by means of the pump, alternately over the material and through the spindle, the circulation being assisted by the use of the steam injector, which also ensures the temperature of the liquors being maintained at 100° C., or more.—F. M.

Dyeing half-wool or half-silk goods with sulphide dyestuffs; Process for reserving the wool or silk in —. Farbwerk Mülheim vorm. A. Leonhardt und Co. Ger. Pat. 212,951, Sept. 12, 1908.

WHEN "protamol" (Färber Zeit., 1908, 266) is added to the sulphide dye-bath, the wool or silk in half-wool or half-silk goods remains undyed: the temperature of the dye-bath is preferably 30°–40° C.—T. F. B.

Waterproofing fibrous materials. A. O. Tate, Toronto, Canada. U.S. Pat. 933,861, Sept. 14, 1909.

THE material is heated with a substance of a soapy nature in order to render the interior fibres non-capillary. It is then immersed in an electrolytic bath and "palmate of aluminium" is deposited on one or both of its sides.—S. H. H.

Artificial lace fabric and the like; Method of producing —. M. Ratignier and H. Pervilliac, Lyons, France. U.S. Pat. 934,214, Sept. 14, 1909.

Recovery of alcohol and ether lost in the air during the manufacture of artificial silk. Fr. Pat. 401,182. See I.

VII.—ACIDS, ALKALIS, SALTS, AND NON-METALLIC ELEMENTS.

Sodium chloride; Boiling point of —. F. Emich. Ges. Deutscher Naturforscher u. Aerzte, Sept. 1909. Chem.-Zeit., 1909, 33, 1015.

WHEN sodium chloride is introduced into an iridium flask which is heated to a temperature of about 2000° C., the rate of vaporisation is so rapid as to be almost explosive. The temperature at which vaporisation commences has now been determined by gradually raising the temperature of an electrically heated iridium plate, until the sample of salt swells up and disappears. This temperature (optically determined) corresponds with the melting point of platinum, i.e., about 1750° C.—F. M.

Sodium hypochlorite; Electrolytic preparation of —. W. Oglöblin. J. Russ. Phys.-Chem. Ges., 1909, 41, 670–679. Chem. Zentr., 1909, 2, 1177–1178.

FROM results obtained with an apparatus of the Keller type for the electrolytic production of sodium hypochlorite from common salt, the author draws the following conclusions. In a given period of time, with constant temperature, E.M.F., and current-strength, the yield of sodium hypochlorite is higher the greater the concentration of the salt solution. The yield is also increased by keeping the quantity of electrolyte small, having as few interruptions in working as possible, and using a high current-strength and low temperature. Electrolytically prepared sodium hypochlorite solution suffers less decomposition on exposure to light and air than a bleaching powder solution of equivalent concentration.—A. S.

Copper sulphate; Influence of temperature on the decomposition of — in a current of dry air. W. Wanjukow. J. Russ. Phys.-Chem. Ges., 1909, 41, 688–717. Chem. Zentr., 1909, 2, 1124.

CRYSTALLISED copper sulphate was heated in a porcelain boat in a porcelain tube contained in a Heraeus furnace, a current of dry air being passed through the tube, and the temperature measured just above the boat by means of a thermo-couple. The results obtained were as follows:—The formation of the hydrate, $\text{CuSO}_4 \cdot 3\text{H}_2\text{O}$, is complete at 30° C. Between 93° and 98° C. the hydrate, $\text{CuSO}_4 \cdot \text{H}_2\text{O}$, is formed, and above 98° C. formation of the anhydrous salt commences, being complete at 232° C. The anhydrous salt is stable up to 341° C., but above this temperature evolution of sulphur dioxide begins. Between 341° and 621° C. there is formed a brown oxy-salt, $8\text{CuO} \cdot 3\text{SO}_3$, which gives a blue hydrate with boiling water. Between 621° and 670° C. both sulphur dioxide and sulphur trioxide are evolved, and an orange-coloured oxy-salt, $2\text{CuO} \cdot \text{SO}_3$, is formed, which also yields a blue hydrate. This orange-coloured salt begins to decompose at 704° C., but decomposition is still not complete at 850° C.—A. S.

Alcohol for use in preparing sodium hydrosulphite; French denaturation tax on —. Board of Trade J., Sept. 30, 1909. [T.R.]

IN virtue of a Ministerial Decision, dated July 8th, 1909, sodium hydrosulphite in powder shall pay, in addition to the Customs duty applicable to "salts of soda not specially mentioned," the denaturation tax on the alcohol used in

its preparation on the basis of 4 centilitres of alcohol per kilo. of the salt. (Hitherto the denaturation tax has been payable on the basis of 50 centilitres of alcohol per kilo.)

Sulphur industry of Italy. U.S. Cons. Rep., Sept., 1909. [T.R.]

The following figures show the amount of raw sulphur produced and exported in Italy and Sicily from 1905 to 1908:—

Year.	Tons.	
	Production.	Exportation.
1905.....	568,927	384,428
1906.....	499,814	336,339
1907.....	426,972	297,378
1908.....	443,720	330,093

The production of sulphur in Sicily itself, which produced nearly all the sulphur mined in Italy, is shown by the following figures:—

	1903.	1907.	1908.
	Tons.	Tons.	Tons.
Production of Sicily.....	522,274	399,672	413,580
Exports to:—			
Italy proper.....	46,974	57,743	60,134
France.....	79,727	59,868	96,448
Other European countries.....	180,194	188,283	171,955
United States.....	157,259	4,073	12,484

Stock unsold.....	363,495	396,445	618,459
Average price per ton.....	778.	748.	758.

Graphite production in the United States. U.S. Geol. Survey, 1908. [T.R.]

NOTWITHSTANDING the steady increase in the use of graphite in the manufacture of lubricants, rust-resisting paints, etc., there was a decline in the output of this mineral in 1908. During the year in question domestic graphite was produced by only sixteen firms, to the amount of 2,587 tons, compared with 29,277 tons in 1907. The great decrease is due principally to the fact that the Georgia firms, which in 1907 produced a large number of tons of graphite for use in fertilisers, suspended operations during 1908. As, however, the value of this material is only about \$1.25 per ton the falling off in the value of the total graphite production of the United States from \$296,970 in 1907 to \$208,090 in 1908 is not commensurate with the decrease in the tonnage.

The manufacture of artificial graphite on a commercial scale is conducted at Niagara Falls, using electric power generated at the Falls. At present the output of artificial graphite is greater than the production of natural crystalline graphite in the United States. In 1908 the production of artificial graphite amounted to 7,385,541 pounds, valued at \$502,667, as compared with 6,590,000 pounds, valued at \$481,239, in 1907. Pure amorphous carbon appears to be converted into graphite only very slowly in the electric furnace at atmospheric pressures. The conversion appears to take place on a commercial scale only when certain amounts of impurities, usually silicious, aluminous, or ferruginous, are present. These need not form more than 3 per cent. of the total mass. Anthracite coal, with a small amount of finely distributed ash, has yielded the best results commercially; an anthracite, with 5.78 per cent. of ash, has yielded a graphite with only 0.03 per cent. of ash. The earlier productions of artificial graphite were not as soft and unctuous as much of the natural graphite, but in 1906 a process of manufacturing graphite of this type was devised which has since been used in increasing quantities for lubricating purposes. This so-called "defoliated graphite" is said to be produced by adding small quantities of gallotannic acid and ammonia to oil or water mixed with very fine graphite. The latter, it is claimed, will

then remain in suspension almost indefinitely and can thus be fed through ordinary oil cups.

In spite of the development of the manufactured or artificial graphite by the electric furnace, the demand for the natural product has increased very largely in recent years because of the increased need for lubricants and the development of electric machinery which calls for graphite products.

Sicilian sulphur and the direct application of sulphur ore in the manufacture of sulphuric acid. G. A. Bruhn Chem. Ind., 1909, 32, 560—565.

THE author considers it doubtful whether the proposals of the Italian parliamentary commission will suffice to put the Sicilian sulphur industry again in a satisfactory position (see this J., 1908, 684; 1909, 937). Much more promising is the proposed use of the sulphur ore directly as a raw material for the manufacture of sulphuric acid, as recommended by Oddo (this J., 1908, 222, 560). In mining the sulphur ore a large proportion (20 per cent.) of "small" (*sterro*) is produced, which is much richer than the main bulk of the ore, containing, on the average, at least 40 per cent., frequently 50 per cent., and in some cases as much as 80 per cent. of sulphur. Under present conditions this "sterro" with a content of 40 per cent. of sulphur, could be delivered at Sicilian ports at a cost of 11 lire (8s. 9½d.) per ton or 27.5 centesimi (2.64d.) per unit of sulphur. The selling price of Spanish pyrites (47 per cent. of sulphur) may be taken as 15 lire (12s.) per ton f.o.b. Seville, or 32 centesimi (3.07d.) per unit of sulphur. This leaves a margin for profit, etc., of only 4.5 centesimi (0.43d.) per unit of sulphur for the Sicilian sulphur ore, but the position would be much more favourable if "sterro" with a higher content of sulphur than 40 per cent. were put on the market, and the Italian Government were to give facilities for the cheap transport of the ore on land. Taking the 1907 figures as a basis, the annual production of Sicilian crude sulphur ore is 2,590,000 metric tons, of which 500,000 tons consist of "sterro," containing 200,000 tons of sulphur, an amount sufficient for the production of one-fifth of the total world's consumption of sulphuric acid. These 500,000 tons of "sterro," if treated by the ordinary methods, yield 80,000 tons of fused sulphur, so that if they were utilised as raw material for sulphuric acid manufacture, the annual production of sulphur, as such, in Sicily would be reduced from 400,000 to 320,000 tons, as against a demand for 350,000 tons, leaving a quantity of 30,000 tons to be obtained from the large accumulated stocks of Sicilian sulphur.

In the author's opinion, the problem of the utilisation of sulphur ore as a raw material for the manufacture of sulphuric acid would be best solved by the installation of new works in Sicily itself or near Sicily. This has already been done in one case, a large company having been formed for the manufacture at Messina of sulphuric, tartaric, and citric acids, etc.—A. S.

Determination of phosphoric acid. Grete. See XXIII. Inorganic Quantitative.

PATENTS.

Sulphuric acid; Apparatus for making — [by the chamber process]. F. J. Falding, New York. U.S. Pat. 932,771, Aug. 31, 1909.

THE apparatus comprises a source of sulphur dioxide, A (see Fig.), Glover tower, B, lead chamber, C, cooling means, D, for the reaction products, and a Gay-Lussac

tower. E. Relative zones of reaction and inaction are secured in the chamber by constructing this with its vertical axis in the proportion of about 3 to 2 over any horizontal axis. (See also Falding, this J., 1909, 1032.) —F. SODX.

Lime and carbonic acid gas; Manufacture of —, T. M. Thom, Cheshunt, and H. Pryor, Saffron Walden. Eng. Pat. 20,102, Sept. 24, 1908.

LIMESTONE is heated in closed retorts arranged vertically around a central combustion chamber, beneath which is a furnace; holes are provided in the walls of the combustion chamber for the passage of the products of combustion, and the whole apparatus is enclosed in a casing which excludes air from the retorts. Superheated steam is admitted to the retorts at their lower ends, and this decomposes the limestone and carries the carbon dioxide through outlets at the top of each retort, leading to a collecting gas main running round the top of the casing. The retorts have closely fitting mouthpieces above and below, at which they are charged and discharged respectively. Perfect combustion and the fullest use of heat from the waste gases is obtained by a system of primary and secondary air and waste gas flues. It is claimed that carbonic acid gas is obtained with this apparatus in a pure state. —F. SODX.

Calcium silicide; Process of producing —, T. L. Willson and M. M. Haff, Ottawa, Canada. U.S. Pat. 934,379, Sept. 14, 1909.

CALCIUM silicide is prepared by heating together calcium carbide and silica, with or without carbon, in the electric arc. The production of other alkaline-earth silicides is also claimed. —F. SODX.

Potassium nitrate and sodium nitrite; Process for the simultaneous manufacture of —, Soc. "Le Nitrogène." Fr. Pat. 400,958, Mar. 18, 1909. Under Int. Conv., Mar. 24, 1908.

For the separation of the mixture of nitrate and nitrite formed by the absorption of oxides of nitrogen, from mixtures of these with air, by milk of lime, the neutral solution is treated with potassium and sodium sulphates or carbonates, in such quantities that the potassium salt is equivalent to the nitrate and the sodium salt to the nitrite present; after separation of the precipitated calcium sulphate or carbonate, the potassium nitrate and sodium nitrite are obtained from the solution by successive crystallisations. The potassium and sodium salts may also be added before absorption of the oxides of nitrogen by the lime; or, the same end may be reached by using for the absorption a mixture of sodium and potassium hydroxides, or such of their salts as are decomposed by nitrous and nitric acids, in the proportion in which nitrite and nitrate respectively are subsequently produced. —F. SODX.

Decolorising product, composed of solid anhydrous sodium hydrosulphite and zinc dust. Badische Anilin und Soda Fabrik. Fr. Pat. 401,000, Mar. 5, 1909. Under Int. Conv., Jan. 30, 1909.

CLAIM is made for a decolorising product, which is composed of solid anhydrous sodium hydrosulphite and zinc dust, and for its industrial applications. The new product, prepared, for example, by intimately mixing 100 kilos. of solid anhydrous sodium hydrosulphite (90 per cent.) with 10 kilos. of zinc dust, is said to keep better when wet than sodium hydrosulphite and to be more active; it ends itself specially to the bleaching of straw, leather, lue, and feathers. —F. SODX.

Stannic chloride; Process of manufacture of —, Soc. Industrielle de Produits Chimiques. Fr. Pat. 401,125, Mar. 23, 1909.

IRON, or material containing it, is treated with dry commercial chlorine, in the presence of some suitable liquid, on which chlorine has no action, such, for instance, as stannic chloride itself. A current of chlorine is passed into the mixture, which is contained in a distillation apparatus, provided if necessary with an agitator, and the

reaction is started by raising the temperature to 50°–110° C.; the stannic chloride produced is distilled off, and the last traces are carried over by a current of air, when chlorination is finished. It is claimed for the process, that local heating and consequent partial oxidation of the tin by impurities in the chlorine are avoided. —F. SODX.

Compounds containing active oxygen; Process for the preparation of —, E. Merck, Ger. Pat. 213,457, Sept. 6, 1907.

SALTS of alkali peroxide-hydrates, especially alkali peroxide-sulphates and alkali peroxide-carbonates, are obtained by the interaction of alkali bisulphates or bicarbonates with alkaline-earth peroxides or peroxide-hydrates. For example, sodium peroxide-carbonate is obtained by the interaction of sodium bicarbonate and barium peroxide-hydrate: $\text{Ba}(\text{OH})_2 \cdot 2\text{NaHCO}_3 \rightarrow \text{BaCO}_3 + \text{Na}_2\text{C}_2\text{O}_4 + 3\text{H}_2\text{O}$. —A. S.

Barium sulphate; Process of bleaching natural —, Soc. Générale d'Etudes et d'Organisations Industrielles, Commerciales, et Financières. Fr. Pat. 401,325, Mar. 22, 1909.

NATURAL barium sulphate is treated with an acid sulphate capable of interacting to form soluble salts with the impurities present; after extraction with water, pure white barium sulphate, which is claimed as a new product, is obtained. For example, 100 kilos. of potassium bisulphate are melted, and a little strong sulphuric acid and 150 kilos. of the finely powdered barium sulphate are added; the temperature is raised, and heating continued, until the reaction is complete, and then water is added to the cooled mass and the barium sulphate separated, the acid sulphate being recovered. —F. SODX.

Hydrogen gas; Mixture for manufacturing —, G. F. Brindley, San Francisco, Cal., and P. M. Bennie, Niagara Falls, N.Y. U.S. Pat. 934,036, Sept. 14, 1909.

THE mixture consists of finely-divided aluminium and molten sodium hydroxide, free from water, the proportion of the latter being between 1 and 3 mols. to 1 mol. of aluminium. Silicon and zinc may also be added. —F. SODX.

Sulphur and other substances; Apparatus for the continuous sublimation of —, E. F. J. Bert. Fr. Pat. 401,923, July 2, 1908.

THE apparatus, which is described chiefly with reference to sulphur, comprises a hopper, from which the crude material is automatically fed into a vessel, heated by waste heat, in which it is melted, the impurities being deposited and removed, and the liquid sulphur rising through a filtering device immersed in the liquid; the nearly pure sulphur passes then to a number of tubular retorts of fairly thin steel or iron, the surface of which may be suitably protected; these are heated in one common furnace, and the sulphur vapour passes from them to the collecting chambers through condensers cooled by water, the temperature of the chambers being thus kept suitably low. It is claimed for this apparatus, that a much increased yield with a given expenditure of fuel is obtained, and the loss of time and heat due to frequent cleaning of the retorts is avoided. —F. SODX.

Electrolysis of alkali chlorides; Apparatus for the —, J. Billitzer, Vienna. U.S. Pat. 934,385, Sept. 14, 1909. SEE Fr. Pat. 376,329 of 1907; this J., 1907, 1015. —T. F. B.

VIII.—GLASS, POTTERY, AND ENAMELS.

Alundum; Manufacture of ——. Mining World, Oct. 2, 1909. [T.R.]

THE abrasive known as "alundum" is manufactured at Niagara Falls. Crude bauxite is calcined in a rotary calciner 60 ft. long, heated by two gas producers; the machine is continuous and will calcine 40 tons of bauxite per day. The ore after calcination is ready for the electric furnaces. These consist of conical pots which stand on cars and are heated by vertical electrodes, which are gradually raised as the molten bauxite fills the furnace. In the furnace room 2000 electric horsepower are used. The dimensions of the furnaces are calculated so that the fusion shall not extend to the water-cooled shell. During the fusion iron is reduced from the bauxite as a result of the reducing action of the electrodes. This iron, containing 5 to 12 per cent. silicon, is sold to the steel makers in masses or "pigs" each weighing about 3 tons. After the completion of the fusion, the furnace is taken under an electric crane, which removes the solidified mass and places it on the cooling floor until it is cool enough to handle. The mass is then broken up and fed to a crusher, after which the alundum passes through a reel which removes all the fine dust, which is re-fused. The product which has gone over the reel is passed over a sorting belt, where the material not up to the standard is picked out. The resulting product in fragments about the size of a man's fist is then subjected to the various operations necessary for use in the alundum wheels.

One of the recent applications of alundum is as a refractory material. The substance melts at 2300° C., and has a very low coefficient of expansion. It is, moreover, very inert, and tests made in the basic open-hearth furnaces show that it is not appreciably affected by slags in these processes. The lining of a Deville furnace does not show deterioration after repeated burns at 1800° C.

PATENTS.

"Slip" or like material employed in the manufacture of china, earthenware, and like goods; Means for purifying the ——. G. C. Solon and A. J. Campbell, Stoke-on-Trent. Eng. Pat. 18,482, Sept. 3, 1908.

THE apparatus, which is arranged preferably below the bottom sieve of the slip-sifting machine, consists of a series of movable frames each carrying a number of electro-magnets; the frames are supported in such a way that the magnets become energised by suitable contact devices when the frames are immediately under the sieve. The cores of the magnets project upwards through holes in the frames somewhat larger than themselves, and the finely-divided slip is made to pass through these holes, thus coming into very intimate contact with the magnets which retain metallic particles. Periodically, the frames are pushed forward by a device connected with an eccen-

tric, and, as each is removed out of position under the sieve, it is automatically demagnetised, and is then picked up by an endless chain and made to pass through a water trough, where the accumulated metallic particles are washed away from the magnets, the latter being then carried by the chain into operative position again; the magnet cores are thus always in effective condition for attracting the maximum amount of metallic particles present in the slip. The invention may be used for removing these impurities from slip or any other potters' materials, either dry or wet.—F. SONS.

Glass melting furnaces or ovens. C. Royer, Gisors, France. Eng. Pat. 20,393, Sept. 28, 1908.

SEE Fr. Pat. 390,102 of 1908; this J., 1908, 1021.—T. F. B.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

Plaster of Paris; Examination of ——. O. Frey, Tonind. Zeit., 1909, 33, 1229—1230.

COMMERCIAL plaster of Paris may contain the following constituents, which can be determined by analysis: (1), Calcium sulphate semi-hydrate, $\text{CaSO}_4 \cdot \frac{1}{2}\text{H}_2\text{O}$; (2), soluble anhydrite, CaSO_4 ; (3), "flooring-plaster," CaSO_4 ; (4), dead-burnt plaster, CaSO_4 ; (5), raw gypsum, $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$; (6), natural anhydrite, CaSO_4 ; (7), impurities other than calcium sulphate. To determine the amount of semi-hydrate (1), 5 grms. of the plaster are made into a thin paste with water, allowed to stand for half an hour, and dried at 60° to 70° C. until the weight remains constant. The increase in weight is due to the amount of water required for the complete hydration of the semi-hydrate and of the soluble anhydrite present. If y be the weight of semi-hydrate, z the weight of soluble anhydrite, and a the increase in weight after complete hydration, $y = 5.37(a - 0.26z)$. To determine z , the amount of soluble anhydrite present, another 5 grms. are allowed to stand over water in a well-fitting bell-jar for 7 days, at the end of which all the soluble anhydrite will have been converted into semi-hydrate. After drying at 70° C. to constant weight, and calling the increase in weight, b , the amount of soluble anhydrite, z , is given by the equation, $z = b \times 15.11$. "Flooring plaster" is that portion of the gypsum which has been heated to a red heat, and which is intermediate between normal and dead-burnt plaster. Taking the same quantities of plaster and of water as for the determination of semi-hydrate, the paste is allowed to remain in air saturated with aqueous vapour for 7 days, at the end of which it is dried as before. If e be the amount of "flooring-plaster" present, c the total increase in weight, and a the increase in weight due to the hydration of the semi-hydrate, $e = (c - a) \cdot 3.78$. To determine the remaining "inactive" constituents of the plaster, the total amount of calcium sulphate present is first determined by dissolving in hydrochloric acid and precipitating as barium sulphate. To the weight of calcium sulphate found in this way, is added the amount of combined water contained in the original plaster (which is separately determined by finding the loss of weight on ignition), and their sum, G , less the sum of the active constituents, (1), (2), and (3), already determined, represents the weight of inactive gypsum present, $t + r$, where t is the sum of the weights of dead-burnt plaster and natural anhydrite, and r the amount of raw gypsum. The latter is calculated from the equation $r = (t - y \cdot 0.062) \cdot 4.78$, in which r is the loss on ignition of 5 grms. of the plaster, and y is the weight of semi-hydrate present. The amount of foreign matter is finally determined by difference.—O. R.

PATENTS.

Artificial stones; Manufacture of ——. H. M. J. Soufflet. Fr. Pat. 401,261, July 15, 1908.

NATURAL or artificial corundum or emery, melted bauxite or alumina, are introduced into an agglomerate formed of cement, porphyry and granite, for the production of paving stones, etc.—B. N.

Cement clinker; Process of making —, and apparatus therefor. C. Ellis, White Plains, N.Y., Assignor to Pitte Street Patents Co., New Jersey. U.S. Pat. 934,056, Sept. 14, 1909.

THE apparatus consists of communicating superposed rotary cylinders, the flame and gases heating the lower cylinder being able to pass by a conduit to the upper one. In the upper cylinder, which is adapted for calcination, the raw cement material is deprived of carbon dioxide, and it is then removed and ground by appropriate means, and made to enter the lower cylinder, where it is burnt to clinker.—F. SODX.

X.—METALS AND METALLURGY.

Iron; Corrosion of — in the earth (gas and water mains) by stray currents from tramway lines. F. Haler and P. Krassa. Z. Elektrochem., 1909, 15, 705—712.

A CONTINUATION of the investigations of Haber and Goldschmidt (this J., 1906, 186) and discussion of the conditions affecting corrosion. A large number of observations and experimental results are given, but no conclusions are yet drawn from them. The authors are of opinion that the access of atmospheric oxygen to underground junctions of different metals has much to do with the possibility of corrosion; and they still consider that as long as positive currents flowing from mains do not exceed 0.75 milliampère per sq. dm. the danger of electrolytic corrosion is but slight.—J. T. D.

Iron; Corrosive power on —, of alternating and of frequently reversed continuous currents. F. Bergius and P. Krassa. Z. Elektrochem., 1909, 15, 712—717.

CAST iron, in water, is practically unaffected by alternating currents of a frequency of 15 to 50. Continuous currents, reversed every 1 to 4 hours, produced no corrosion greater than that produced when the current was not reversed. Much greater corrosion occurs while the current is passing than when no current flows, and the amount of it depends very much on the condition of the surface. The "skin" on a casting affords protection against electrolytic as well as against chemical corrosion.—J. T. D.

Copper-ore; Obtainment and treatment of — at the Oss-Mazzurana works in Predazzo, S. Tyrol. F. Oss-Mazzurana and R. Hesse. Metallurgie, 1909, 6, 569—596.

THE Oss-Mazzurana copper mine with its associated works for the production of copper sulphate is situated on Mt. Mulât near Predazzo in the South Tyrol. The authors discuss the geological and mineralogical formation of the mountain, which latter includes copper pyrites, pyrites, tourmaline, scheelite, and magnetite. The copper ore contains about 4.6 per cent. of copper, 15.2 per cent. of sulphur, 3.6 per cent. of iron oxide, 1.5 per cent. of tungstic acid, and 2 grains of gold and 35 grains of silver per ton; the pure copper pyrites contains 34 per cent. of copper, and the scheelite 79 per cent. of tungstic acid, and 4 oz. of silver and 0.2 oz. of gold per ton. A detailed scheme of "dressing," including the most recent methods of crushing and grading the ore, is described, whereby scheelite containing 70 per cent. of tungstic acid and a concentrate containing 20 per cent. of copper are obtained. The ore is roasted in a cylindrical iron drum, heated by three oil-injectors, the air supply to which can be perfectly controlled. A thermoelectric junction of iron and constantin inserted in an iron tube in the drum is connected with a recording pyrograph, and also with an alarm set at the maximum temperature desired. The operation needs very close supervision to ensure the whole of the copper being finally obtained as copper sulphate. With poor concentrates the temperature is maintained at about 450°—480° C. for some hours to form directly the copper sulphate. The temperature is then raised to 560° C., when the ferrous sulphate produced is decomposed into ferric oxide, without affecting the copper salt. With rich concentrates the temperature is from the start

rapidly raised to about 600° C. in order to obtain copper oxide, which is of importance for the removal of iron at a later stage. It is found that when a temperature of 420° C. is reached, the injectors can be stopped, the combustion of the sulphur being sufficient to raise the temperature of the mass to between 500° and 610° C. Considerable economy of oil is thus effected. The roasted mass is lixiviated with dilute sulphuric acid, and treated with copper oxide in a current of air to convert the ferrous sulphate into copper sulphate and ferric oxide. After the solution has been filtered, and concentrated, crystallised copper sulphate of a very high grade of purity is obtained.—A. H. C.

Alloys; Alteration of the physical properties of — by mechanical and thermal treatment. E. Pannain. Atti R. Accad. dei Lincei, Roma, 1909, [5], 18, 1., 700—701. Chem. Zentr., 1909, 2, 900—901.

THE author's experiments were made with coinage alloys, viz., bronze containing about 4 per cent. of tin, and a silver-copper alloy containing 16.5 per cent. of copper. The structural alterations of these alloys during mechanical and thermal treatment have been previously described (see this J., 1909, 246, 838). It has now been found that the specific gravity of the bronze (8.76965 at 16° C.) increases during its manufacture into coins, rising to 8.94623 after stamping. The greatest increase (0.1618) was caused by the rolling after the first heating; stamping only increased the specific gravity by 0.00006. The specific gravity (at 18° C.) of the silver alloy rose from 9.99932 to 10.21636 during the entire process, the first rolling causing an increase of 0.20038. It is stated that during the heating, the alloys regain their original ductility, without the compactness caused by rolling being impaired.—A. S.

Tantalum and niobium; Determination of —, and their separation from silica in minerals, steel, and alloys. W. E. von John. Chem. News, 1909, 100, 154.

FOR the determination of tantalum and niobium in minerals, these are decomposed by fusion with potassium bisulphate; the cooled melt is boiled with water, and the insoluble matter washed, first with hot water, then with hot yellow ammonium sulphide, then with hot water and dilute sulphuric acid, and finally with hot water again; the residue, consisting of silica and tantalum and niobium acids, is ignited and weighed. This residue is next fused with sodium hydroxide, and the melt dissolved in cold dilute sodium hydroxide solution, the insoluble sodium tantalate and niobate being separated from the soluble sodium silicate by filtering through a Gooch crucible and washing with dilute sodium hydroxide; the residue is washed with lukewarm water, until no precipitate is obtained with dilute sulphuric acid, and the tantalum and niobium are precipitated from the somewhat cloudy washings by boiling for a few minutes with dilute sulphuric acid; the precipitate is ignited and weighed. This residue is then fused with potassium hydroxide, the melt is dissolved in water, and again precipitated by boiling with dilute sulphuric acid; the precipitate is filtered off and dissolved in hydrofluoric acid, and, after the addition of some potassium fluoride, the solution is boiled for a few minutes, then diluted and boiled again. The tantalum is thus separated as potassium tantalum oxyfluoride; this is washed with cold water, until no reddish precipitate is obtained with tincture of galls, concentrated sulphuric acid is added, and the hydrofluoric acid is driven off by gentle heating; tantalum acid and potassium bisulphate are thus formed, and the latter is extracted with water, the residue being ignited and weighed. For the determination of tantalum in steel or alloys, containing up to 45 per cent. of tantalum, the turnings are dissolved in hydrochloric acid, the solution is evaporated to dryness, and the residue treated with dilute sulphuric acid; silica, carbonaceous matter, and tantalum remain insoluble, and the mixture is washed, ignited, and weighed; it is then fused with sodium hydroxide and treated as above described. Alloys containing more than 45 per cent. of tantalum are ignited, and then treated as in the

case of steel, or, in presence of tin, as described for minerals. The above methods are said to be rapid and well suited for use in commercial analysis.—F. SOPH.

Elmore's ore-extraction process. R. Glatzel. *Erzbergbau*, 1909, 285. *Chem.-Zeit.*, 1909, 33, Reps. 512.

THE method depends upon the selective attraction of certain minerals for oil. A mineral becomes coated with oil if the difference in surface tension between water and mineral on the one hand and oil and mineral on the other is greater than the tension between oil and water. A viscous mineral oil is used. The following minerals become coated with oil:—Gold, cinnabar, nickeline, galena, mispickel, argentite, rammsbergite, pyromorphite, cassiterite, smaltite, ulmannite, cerussite, bismuthite, cobaltite, scheelite, goetschite, cuprite, pyratgryrite, bornonite, chalcocite, chalcopyrite, pyrites, hornite, freibergite, molybdenite, marcasite, fahl ore, magnetic pyrites, antimonite, tin pyrites, zinc blende, malachite, graphite, and sulphur. The following do not become coated: Magnetic iron ore, hematite, limonite, spathic iron ore, psilomelane, pyrolusite, yellow zinc blende, calamine, wolframite, quartz, heavy spar, fluor spar, calc spar, ankerite, dolomite, and felspar. It is possible that the applicability of the process could be further extended by using saline solutions in place of water.—A. S.

"Cork Metal." F. J. Willott. *Chem. News*, 1909, 100, 162.

AT one of the recent aeronautical exhibitions, samples of a metal were shown under the name of "cork metal," which was said to be 40 per cent. lighter than aluminium, and to have numerous other properties which should make it a rival of the latter. In appearance the metal resembles very strongly the alloys known as magnalium. The surface presents a lustreless whitish grey colour, both sheets and bars showing the scorings and scratches so frequently found on badly rolled or drawn aluminium. Careful analysis gave the following result:—Aluminium, 0.04; iron, 0.017; zinc, 0.48; sodium, 0.21; magnesium, 99.30 per cent.

Refractory metals from their chlorides. Pring and Fielding. *See H.*

PATENTS.

Metallurgical [zinc] condenser. W. M. Johnson, La Harpe, Kans., Assignor to The Continuous Zinc Furnace Co., Hartford, Conn. U.S. Pat. 933,843, Sept. 14, 1909.

A ZINC furnace is connected with a condenser having means for cooling and a series of baffle-walls upon which are arranged carbon resistances for the purpose of independent heating.—F. R.

Converters. Comp. Générale des Aciers. Fr. Pat. 400,820, March 15, 1909.

THE converter is of the improved Bessemer type, but several modifications have been introduced. The hearth of the furnace is rectangular in section, and two superimposed rows of tuyères are provided; these are completely independent, the top row supplying a current of air, which can be increased or cut off at will, above the surface of the molten metal. The manner of working is arranged as follows:—In order to bring the interior lining and the mouths of the tuyères to the requisite temperature, the converter is charged with a sufficient amount of burning combustible, and, its mouth being covered with a grating, is inverted. The mouth is then connected with a tuyère, and a current of air is passed up through the grating, the products of combustion passing away through the ordinary air holes used as tuyères in the subsequent operation. When the interior has been raised to a white heat, the fire is drawn and the apparatus charged with the requisite amount of molten metal. In the first phase of blowing, the air is led along the surface of the iron from the lower row of tuyères only, so that an intimate contact of air and metal is obtained. When the first phase is completed, that is, when the metal becomes so hot that the carbon commences to oxidise, the pressure of the blast proceeding from the lower holes is diminished by opening one or more

of the upper ones. In this way the temperature of the converter is maintained within the desired limits. It is finally claimed that, by giving to the hearth a rectangular section with rounded corners, there is a noticeable decrease in the consumption and pressure of the air employed, as well as in the loss of metal through the projection of cinders.—C. A. W.

Solder for platinum. D. de Benedetti. Fr. Pat. 400,827, June 25, 1908.

THE solders, which are intended mainly for use in the manufacture of jewellery, are composed of platinum and gold, or of platinum, gold, and fine silver. The gold, which should be preferably the "green" metal of 75 per cent. fineness, is weighed out, and if necessary alloyed with the required amount of silver. A sheet of this alloy is then used as a wrapping for the platinum in the form of spangles, the proportions of metal taken being calculated according to the required composition. The whole, after being rolled into a ball, is covered with borax and heated in the oxyhydrogen flame. The product is rolled out and the operation repeated two to three times. As examples, the compositions, platinum 60, gold 35, fine silver 5 parts; and platinum 25, gold 50, and fine silver 25 parts, may be cited.—C. A. W.

Nickel; Production of pure —. Soc. Electro-Métallurgique Française. Fr. Pat. 400,910, June 27, 1908.

THE method consists in casting, as a preliminary operation, a nickel alloy containing nickel, iron, carbon, and silicon in varying proportions according to the ore and the composition of the reducing agent employed. The molten alloy is then deprived of most of its iron, either by heating in a Bessemer furnace or by simple pulverisation in a jet of air, a treatment in a reverberatory furnace completing the operation. The product, which is composed mainly of metallic nickel, metallic iron, and the respective oxides, is subsequently re-smelted in an electric furnace, when the oxide of iron passes into the slag, the nickel remaining behind as a bath of metal. In order to obtain the latter free from iron, carbon, and silicon, it is necessary that a small quantity of nickel oxide be present in the slag.—C. A. W.

Wood; Process and apparatus for the distillation of —, with recovery of by-products and direct utilisation of the charcoal for metallurgical purposes. Soc. des Hauts Fourneaux, Forges, et Acieries du Chili. Fr. Pat. 401,226, July 11, 1908.

THE patent relates to the use of wood as fuel for blast-furnaces. Instead of carbonising the wood in a separate plant, the blast-furnace is made sufficiently high for the upper part to serve as a chamber for the slow carbonisation of the wood which is fed in with the ore at the top of the furnace. The by-products are recovered from the furnace-gases in the usual manner.—A. T. L.

Porosity in ingots; Method and apparatus for preventing —. Soc. Anon. Electro-Métallurgique (Procédés P. Grod). Fr. Pat. 401,300, July 16, 1908.

UNDER the ordinary conditions of casting, there is a tendency for the ingot to solidify too rapidly at the head, so that, by reason of the imperfect escape of the upgoing gases through the pasty mass, an unsound and porous metal is obtained. It is therefore proposed to retard the solidification at the top by heating the ingot electrically, either by the direct Joule effect or by the radiations from an arc. In practice, the ingot mould is covered at the top with a small movable metal frame lined with some refractory material, which should be a bad conductor of electricity. The whole is surmounted by a cover provided with a hole in the centre through which passes an electrode. This electrode is suspended, by an insulating hook, below an electric transformer, which can itself be moved vertically when desired. The transformer is connected by conducting cables with the electrode and with the bottom of the ingot mould, which thus forms the second pole. The upper electrode being brought into contact with the head of the ingot, a high-tension current is passed into the transformer, where its voltage is diminished. The arc,

having been started, is maintained by raising the upper electrode to a suitable height, the heat produced being concentrated at the required point by means of the cover on the top of the mould.—C. A. W.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

(A.)—ELECTRO-CHEMISTRY.

Mercurous sulphate for standard cells [and crystallised calomel]. C. J. J. Fox. Brit. Assoc., Winnipeg, 1909. Chem. News, 1909, 100, 150—151.

PURE well-crystallised mercurous sulphate may be prepared from the commercially pure substance by heating it for one or two days with a little pure mercury and dilute sulphuric acid at 120°—150° C. in a closed vessel which is occasionally agitated, the acid being preferably filtered off and renewed during the process of heating. The product is ground in a mortar with one or two successive quantities of dilute sulphuric acid, and then several times with a saturated solution of cadmium sulphate, filtering through a Büchner funnel after each washing. A white crystalline preparation is thus obtained, which is free from nitrate and basic salt and in every way suited for use in standard cells. Calomel may be prepared

in a crystalline form by heating mercury and hydrochloric acid together in a similar manner, though for a longer period.—F. SODY.

Hydrogen peroxide; Influence of — on the properties of platinum. K. Bornemann. Z. Elektrochem., 1909, 15, 673—677.

THE author finds an explanation of the facts that both cathodic and anodic polarisation of platinum have been observed by different authors to render it inactive, in the action on the platinum of hydrogen peroxide, for when a freshly-ignited platinum electrode is dipped into hydrogen peroxide solution, the catalytic decomposition of the peroxide and evolution of oxygen rapidly lessen and cease, though only a negligible quantity of peroxide has been decomposed. This electrode, if now submitted to anodic polarisation in a weak hydrogen peroxide solution, shows a sharp "knick" in the curve connecting voltage and current at 1.23 volts; but if it be now either ignited, or submitted to anodic polarisation in water (weak acid) without hydrogen peroxide, the curve is continuous. The same destruction of the "knick"-producing property is effected to a limited extent by immersing the electrode in oxidising agents such as potassium permanganate; and it is therefore concluded that the property is due to the formation on the platinum of an oxide containing oxygen held similarly to the oxygen in hydrogen peroxide—an "antozonoid" oxide, to use Schönbein's nomenclature. This oxide must be without catalytic activity, and when decomposed by oxidation leaves a lower oxide, the catalytic effect of which is very slight.—J. T. D.

Cadmium arc; New method of producing a —. T. M. Lowry. Brit. Assoc., Winnipeg, 1909. Chem. News, 1909, 100, 161.

IN order to produce a cadmium spectrum of sufficient intensity for polarimetric work, advantage is taken of the favourable properties of the silver-cadmium alloys. On account of their isomerism, the two metals form an excellent series of alloys which are characterised by good mechanical properties and very high melting points. (An alloy with 60 per cent. of cadmium melts as high as 700° C.). In striking contrast to the behaviour of the pure metal the alloy gives a steady arc which can be kept true to centre by rotating the electrodes in opposite directions. The spectrum shows the silver as well as the cadmium lines, but these are so far separated that even with a low resolving power the slit of a spectroscope can be opened to its full width without any overlapping of the brilliant "blocks" of light which take the place of the usual "lines."

PATENTS.

Electric furnaces. C. Bingham, London. Eng. Pat. 26,356, Dec. 5, 1908.

IN order to renew the upper electrode without interrupting the working of the furnace, in furnaces in which the lower electrode is fixed and the upper one is suspended and lowered as required, two or more carriages are arranged to run on a joist over the furnace, with duplicate electrodes suspended therefrom. When required, the new electrode is connected by flexible connections to the same electric supply as that being used and lowered alongside the worn electrode, which is then withdrawn, the flow of current having been gradually transferred from one electrode to the other without interruption of the discharge.—F. R.

Furnace; Electric —. T. F. Baily, Alliance, Ohio. U.S. Pat. 933,815, Sept. 14, 1909.

THE furnace consists of an oven composed of heat-resisting bricks, of low electrical conductivity, arranged in tiers,

having strips of asbestos between each tier. Spaced electrodes are located at opposite ends of the furnace, and a granular resistance body placed on the floor of the furnace connects the electrodes. Midway between the electrodes the area of cross-section of the resistance body is reduced and means are provided for placing an object to be heated, immediately over but not in contact with the resistance body, at this point.—F. R.

Chlorides, sulphates or other alkali salts; Electrolysis of — C. Marie. Fr. Pat. 400,787, June 23, 1908.

The invention relates to the electrolysis of alkali salts, such as chlorides, sulphates, etc., depolarisation of the anode being brought about by means of hydrogen, which is produced at the cathode or which may be formed in any other suitable manner. The hydrogen, or other gaseous reducing agent, is conveyed under a convenient pressure to the anode, the latter being composed preferably of platinum, platinised carbon, or other convenient material.—B. N.

Accumulators and electrolytic apparatus. J. H. Russenberger. Fr. Pat. 401,355, March 27, 1909.

Thin separating membranes are arranged between and in contact with the different electrodes. Collodion is preferably employed as a separating medium, either directly as a coating on the electrodes, or as a layer on an appropriate surface, and the electrodes are thin so as to obtain a large surface area with a minimum of weight. Viscose, "cellite," etc., may be employed in place of collodion, and may be mineralised or not by means of gelatinous silica.—B. N.

Carbon electrodes for electro-analytical purposes; Process of making durable — G. Adolph, Ammendorf, and A. Pietzsch, Assignors to Chem. Fabr. Buckau, Magdeburg, Germany. U.S. Pat. 934,988, Sept. 28, 1909.

(B.)—ELECTRO-METALLURGY.

Iron; Sulphur-content of electrolytic — A. Pfaff. Z. Elektrochem., 1909, 15, 703—705.

A. MÜLLER (this J., 1909, 371) who examined samples of electrolytic iron prepared by a modification of Burgess and Hambuechen's process, found in the metal as first deposited, 0.0099 per cent. of sulphur, ten times the amount which those authors found. As this result did not accord with those of H. Lee (Dissertation, Dresden, 1906), who found no sulphur in any of the samples of electrolytic iron which he prepared, the author has carefully gone over the ground again. His best results were obtained when the electrolyte was a slightly acid concentrated solution of ferrous sulphate, and a high current density (2 amp. per sq. dm.) and temperature (70° C.) were used, the electrolyte being stirred by a current of indifferent gas. The anodes were wrapped in parchment-paper, and the electrolyte was not renewed. The following table shows the results:—

No.	Electrolyte.	Per cent. of sulphur.
1	Ferrous sulphate, weakly acid, 6 per cent.	0.00037
2	Do. do.	0.00023
3	Do. do.	0.00065
4	Do. do.	0.00018
5	Do. do.	0.00065
6	Burgess and Hambuechen's, prepared by Lee	0.00018
7	Ferrous ammonium sulphate, 2 per cent.	0.00265
8	Do. do.	0.00082

In experiments 5 and 7 the precipitates of barium sulphate contained iron, and the results are certainly too high; omitting these, it is safe to say that the amount of sulphur never reaches 0.001 per cent., and is usually far below that. Müller's results, then, though they may be true in the case of the irons prepared and examined by him, have no general application to electrolytic irons.—J. T. D.

Silicomanganese and silicon-spiegel; Preparation and properties of commercial — J. Escard. L'Électricien, 1909, 37, 293.

Four compounds of manganese and silicon have been prepared, viz., SiMn_2 , SiMn , Si_2Mn_3 , and Si_3Mn (see this J., 1896, 141; 1903, 168, 214; 1905, 1235; 1907, 98, 154). Commercial silicomanganese varies in composition and properties. It usually contains from 60 to 70 per cent. of manganese and 20—25 per cent. of silicon, with varying proportions of carbon, iron, and aluminium; products containing 75 and 80 per cent. of manganese can, however, be obtained. A sample which broke easily under the hammer and showed an irregular brilliant fracture, contained 71.5 per cent. of manganese, 23 of silicon, 2.5 of iron, and small proportions of calcium and carbon. It is prepared technically by the reduction of rhodonite, a mixture of quartz and pyrolusite, or a mixture of rhodonite and pyrolusite in an electric furnace. The charges used and electrical energy consumed in preparing 1 ton of commercial silicomanganese: (1), from rhodonite (45.6 per cent. of silica and 38.3 of manganese oxide); (2), from pyrolusite (50 per cent. of manganese) and quartz; and (3), from a mixture of rhodonite and pyrolusite, are shown in the following table:—

	(1).	(2).	(3).
	kilos.	kilos.	kilos.
Rhodonite	2900	—	1000
Pyrolusite	—	1580	1000
Quartz	—	380	—
Coke	420	680	625
Carbon for electrodes	80	65	65
Elect. energy	7100 kilo-watt-hrs.	6300 kilo-watt-hrs.	6200 kilo-watt-hrs.
Cost	£13 2s.	—	£12 14s.

Silicon-spiegel is an alloy containing from 60—65 per cent. of iron, 20—25 of manganese, 10—12 of silicon, and 2—3 of carbon. By reduction of 1 ton of acid Bessemer slag in an electric furnace with 200 kilos. of coke, and a consumption of 25 kilos. of carbon for electrodes, and 2400 kilowatt-hours, 400 kilos. of an alloy containing 25 per cent. of silicon and 35 per cent. of manganese can be obtained, together with a slag rich in silica (see U.S. Pat. 712,925; this J., 1902, 1541). A relatively pure alloy, known as electro-silico-spiegel, containing 22—25 per cent. of silicon, 38 of manganese, and 1 of carbon, is now produced in large quantities by the reduction of a mixture of ferrosilicon, silica, and manganese ore by means of carbon in an electric furnace.—A. S.

PATENTS.

Steel; Manufacture of — W. R. Walker, New York. U.S. Pat. 934,247, Sept. 14, 1909.

MOLTEN iron is first treated in an acid-lined Bessemer converter until the silicon has been substantially eliminated and the carbon reduced to about 0.3 per cent.; it is then transferred to a basic-lined electric furnace, having a non-oxidising atmosphere, for the removal of the phosphorus.—F. R.

Nickel and nickel-copper alloys; Manufacture of — D. H. Browne, Ontario, Canada, Assignor to The Canadian Copper Co., Cleveland, Ohio. U.S. Pat. 934,278, Sept. 14, 1909.

SULPHUR compounds of nickel or of nickel and copper, are reduced to metal by fusion in an electric furnace in the presence of lime. Part of the sulphur is evolved as sulphur dioxide, the remainder combining with the lime to form calcium sulphide.—F. R.

Hollow metallic bodies; Manufacture of — by deposition of several superimposed bodies on a mandrel and subsequent removal of the latter. Fabrik Elektrischer Zünder Ges.m.b.H. Fr. Pat. 400,999, March 4, 1909.

THE present invention may be applied to the manufacture of small metallic cases, primarily composed of some such metal as zinc but lined internally with a thin protective coating of nickel. The metallic layers are precipitated on mandrels of steel or brass which have previously received a thin coating of silver iodide obtained by thinly silver plating and then treating with iodine. The various metals may then be electrolytically precipitated in the required order by transferring the frame holding the mandrels from one solution to another. In order to enable the finished article to be removed more readily from the mandrel, the latter may be polarised anodically.—C. A. W.

Metallisation of non-metallic articles. The Newell Manufacturing Co. Fr. Pat. 401,137, March 23, 1909.

THE invention is intended for application more especially to the manufacture of artificial flowers from the natural blossoms, but other non-metallic articles, such as silk, may be metallised in a similar manner. As an example, a rosebud is taken, and the stem replaced by a double-pointed hat-pin inserted in the calyx nearly up to the top of the flower. The latter is then hardened by immersion in a solution of 200 grms. of shellac in 1 litre of alcohol. After drying for half an hour, it is again immersed and finally covered with bronze powder, which may be dusted over the blossom from a brush. After further drying, it is submitted to a process of electro-plating in an acid copper solution, the pin serving as cathode. The metallised blossom is washed in hot water, dried in hot air, and freed from vegetable material by heating over a Bunsen burner. Finally the surface is cleansed by a three hours' soaking in dilute hydrochloric acid (1 in 4), followed by immersion successively in potassium carbonate solution, and in a mixture of nitric acid (3 parts) and sulphuric acid (1 part). The connection between flower and stem having been rendered rigid by a plaster moulding, the blossom may be tinted to any shade desired by means of lacquer.—C. A. W.

XII.—FATTY OILS, FATS, WAXES, AND SOAPS.

Refractive power of fats; Influence of halogens on the —. W. Storp. Mitt. a. d. Gebiete des Militärsanitätswesens. 1909, Hft. 41, Tl. 3, 84—97. Chem. Zentr., 1909, 2, 1012—1013.

BROMINATED fats were prepared by adding 5 grms. of bromine dissolved in 100 c.c. of glacial acetic acid to 0.5 gm. of the fat dissolved in 15 c.c. of chloroform. The excess free bromine was removed by means of sodium sulphite, and the chloroform solution of the brominated fat was neutralised by means of sodium bicarbonate. The refractive powers of the brominated fats were greater than those of the original fats, in proportion to the amount of bromine fixed. Since the dispersive power was increased concurrently with the refractive power, the author employed red light (an electric incandescent lamp with bulb of red glass) for determining the latter. If for given fat the limiting values for the refractive power of a bromine derivative be determined, then these values may be used in the same way as the iodine values as a measure of the purity of the fat. For this purpose the bromination must always be carried out under strictly

defined conditions, otherwise concordant results cannot be obtained. The method is simpler than the determination of the iodine value, and it can be applied to fats, waxes, and paraffin wax. For an increase of 100 ss in the iodine value of a fat, the refractive power of the brominated fat increases by 9.2 butyrefractometer scale divisions. The limiting values for the refractive power of brominated butter and lard are 57—72 and 74—94, the corresponding iodine values of the original fats being 26—44 and 46—70 respectively.—A. S.

Fats and oils; Theory of the hydrolysis of —. 111. J. Kellner. Chem.-Zeit., 1909, 33, 993.

THE author, experimenting on the same lines as described (this J., 1909, 531), states that the course of hydrolysis in Kretitz's method of saponifying fats by means of lime is quadrimolecular, as in the case of saponification with alkalis. Thus in two experiments the amounts of glycerol found in the partially saponified fat were 7.80 and 4.31 per cent. as compared with 8.04 and 4.31 per cent. theoretically required for a quadrimolecular hydrolysis. In neither case was the presence of mono- or diglycerides indicated. In the experiments on the hydrolysis of fats with hydrochloric acid, expressed palm-kernel oil, with an acid value of 13.4, was boiled for several hours with an equal volume of hydrochloric acid of sp. gr. 1.150. After 8 hours the acid value of the thoroughly-washed fat was found to be 156.2, whilst the saponification value exceeded 260 (in some cases 270), and was thus higher than that obtained in the saponification of the fat with alkali. Absorption of hydrochloric acid had apparently taken place, since after saponification with alkali the fat again showed saponification values of 258 to 260. The presence of mono- and diglycerides was indicated and the author therefore concludes that the hydrolysis of fats with hydrochloric acid is uni- and bimolecular. The curve for the hydrolysis coincides fairly closely with that observed in Twitchell's method. The loss of glycerol of 9.08 per cent. observed by Eisenstein and Rosauer in the hydrolysis of pressed tallow in an autoclave is considered by the author in the light of his experiments to be largely due to the formation of mono- and diglycerides. (See also this J., 1898, 1107; 1899, 1031; 1904, 905; 1906, 856; 1907, 24, 263, 623; 1908, 693).—C. A. M.

China bean oil in Australia; Denaturation of —. Board of Trade J., Sept. 30, 1909. [T.R.]

A CUSTOMS By-Law (No. 58), dated 5th August, amends with effect from 15th July, 1909, the method of denaturation of China oil entered for delivery free of Customs duty in Australia, which is to be as defined in this J., 1909, 250, when the oil is for use other than for soap making.

When for use in the manufacture of soap, the oil, when opened, must (a) at once be mixed with soap stock. (Prior to such mixing the Collector of Customs shall be satisfied that mixture with such stock will constitute effectual denaturation of the oil), or (b) be denatured by the addition to each 100 gallons of the oil of 5 per cent. of castor oil, and of 5 per cent. of molten tallow.

Ricinoleic acid; Derivatives of —. R. F. Chonow-ky. Ber., 1909, 42, 3339—3356.

THE ricinoleic acid used in the author's experiments was prepared by "salting out" stearic and palmitic soaps from castor oil soap solution with sodium chloride, then converting the ricinoleic soap into the lead salt, which was treated with ether, and finally converted into the barium salt, the latter being freed from impurities by extraction with ether. On treating this ricinoleic acid with hydriodic acid in the presence of phosphorus and iodine, there was obtained a thick yellow oil, consisting of di-iodostearic acid, $C_{18}H_{31}I_2O_2$, and not iodo-stearic acid, as stated by Claus and Hassenkamp. In the author's opinion the product obtained by them was a mixture of di-iodostearic acid and unchanged ricinoleic acid. When reduced with zinc in acetic acid solution, this di-iodostearic acid yielded only stearic acid (m.p. 70°—71° C.). This supports the statement of Goldschmid and Kasansky that ricinoleic acid contains the

alcoholic hydroxyl group attached to the twelfth carbon atom, whilst the double linkage occurs between the ninth and tenth carbon atoms. It may thus be assumed that in the reduction with hydriodic acid two isomeric di-iodostearic acids are produced, one of which contains the halogen atoms attached to the ninth and twelfth, and the other to the tenth and twelfth carbon atoms. When boiled with alcoholic potassium hydroxide, the di-iodostearic acid yielded a light brown oily fatty acid, $C_{18}H_{32}O_2$, isomeric with linolic acid, which thickened on exposure to the air. It did not yield the ordinary linolic tetrabromide when brominated, but a dark-coloured thick fluid tetrabromide. Moreover, oxidation with alkaline permanganate produced, not tetrahydroxystearic acid, but only a brown resin-like mass, containing azelaic acid, &c. The interaction of zinc oxide and the di-iodostearic acid yielded a product which could be separated, by treatment of the barium salts with ether, into an impure hydroxyoleic acid, $C_{18}H_{34}O_3$ (m.pt., 108° — 114° C.), and a more soluble portion containing an acid with two double linkages. By the action of moist, freshly-precipitated silver oxide upon the di-iodostearic acid, there was produced a dihydroxystearic acid with the hydroxyl groups attached to the tenth and twelfth carbon atoms, together with a small quantity of an oily product consisting, in the main, of an acid resembling linolic acid. On treating ricinoleic acid with sulphuric acid (65° B.) at 0° C., and pouring the product of the reaction into ice-cold water, about 30 per cent. of solid fatty acids could be separated from the oily layer after saponification and the addition of acid. By treatment with ether these could be separated into a sparingly soluble portion melting at 108° to 109° C. (and containing a small amount of a substance melting at 115° — 116° C.), and a soluble portion melting at 73° — 74° C. Analysis showed that these substances were two isomeric glycidic acids contaminated with a little dihydroxystearic acid. The tendency of ricinoleic acid to form glycidic rather than dihydroxy acids may be explained as follows:—The sulphuric acid can form two isomeric sulpho-acids, viz. :—

When these are boiled with water and saponified with potassium hydroxide they are decomposed into sulphuric acid and the two acids—

The first of these reacts with other substances more readily than the second. It forms a diacetyl compound, and is partially converted by the action of potassium hydroxide into the dihydroxystearic acid with the same constitutional formula as that produced by the action of moist silver oxide upon the di-iodostearic acid. This acid differs both in its structure and in its physical and chemical properties from the isomeric dihydroxystearic acids obtained from oleic, iso-oleic and elaidic acids.

Tallow in beeswax; Detection of — A. Ostrogovich and S. Petrisor. Bulet. Soc. Stiinte din Bucuresti, 1909, 18, 127—130. Chem. Zentr., 1909, 2, 1170.

FROM 6 to 7 grms. of zinc chloride are melted in a porcelain crucible, and then 1 gm. of the wax is added. The crucible is covered with a lid, the under side of which has been wetted with 2—3 drops of a solution of 0.3 gm. of phloroglucinol in 100 c.c. of concentrated sulphuric acid. The covered crucible is heated for 35—40 seconds, and then the under side of the lid examined. If the sample of wax contained tallow, the acrolein formed will have

developed with the phloroglucinol reagent a reddish violet colour, which is intensified on addition of a few drops of alcohol (see Barbet and Jandrier, also Istrati this J., 1898, 954). With pure wax, only a faint brown coloration is produced. Very small quantities of acrolein produce only a yellow coloration.—A. S.

PATENTS.

Fatty substances; Process for emulsifying and saponifying — to render them suitable for the manufacture of soaps, etc., and more particularly the cleansing of textile material in general. E. Lasbordes, Fr. Pat. 400,792, Feb. 8, 1909.

THE object of the process is to emulsify fatty substance such as suet, copra, oils, etc., and consists in mixing them at a temperature of about 60° C. with either (1) 10 per cent. of their weight of the mucilaginous matters obtained from linseed, or of gum, starch, etc.; (2) 10 per cent. of soap (3) 3 per cent. of gelatin dissolved in water; (4) from 1 to 5 per cent. of potassium hydroxide, sodium hydroxide or ammonia.—W. P. S.

Fats, butter, and the like; Process and apparatus for sterilising — by means of ultra-violet rays. Soc. L. Ferment. Fr. Pat. 400,921, Mar. 17, 1909.

THE fat, etc., is spread in a thin layer on the surface of a endless band or on a drum. The movement of the band or drum carries the layer of fat past a number of lamps which emit ultra-violet rays. These lamps are provided with a reflector. The fat is removed from the band or drum by means of a scraper after it has passed the lamps and the band or drum may be heated or cooled as desired.—W. P. S.

Soap, fats, and the like; Machines for cooling and moulding. W. Gilbert, London, and S. J. Ralph, Peterborough. Eng. Pats. 18,031, Aug. 27, 1908, and 4950 Mar. 1, 1909.

THE machine consists of a number of vertical moulds which are carried on a table or frame fitted in a cylindrical cooling tank. A measuring device is arranged between the supply vessel and the moulds, and means are provided for rotating the cooling tank, step by step, so that the moulds travel from the measuring device to a number of discharge ramps, the number of moulds being such that the machine may be in practically continuous operation. Provision is made for supplying water to the cooling tank and for circulating it in the tank. The measuring device consists of a drum divided transversely into measuring compartments and in cross-section is formed with two pockets one of which is being filled, while the other is discharging into the mould; it may be heated by a steam jacket. The moulds are provided with discharge valves which are operated by the movement of the ramps. A porous pad may be fitted round the end of each ram, brine being supplied to this pad in order to wipe out the mould at each discharge operation. The machine may be connected with a discharging mechanism consisting of a receiving box which has one side fixed and the other side pivoted on receiving the bars of soap, the movable side is tilted by means of cams so as to bring the end of the bars into contact with a conveyor band which removes them from the box, the latter being then returned to position by means of a counter-weight.—W. P. S.

XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, &c.

(A.)—PIGMENTS, PAINTS.

Paints; Production of mineral — in the United States.
U.S. Geol. Survey, 1908. [T.R.]

The following is an abstract of the report on the production of mineral pigments and paints in the United States in 1908. The mineral paints are arranged in this report in three groups:—(1) natural mineral products which, after mechanical treatment, such as cleaning and grinding, are either used directly as pigments or are first roasted to give certain desired colours; (2) chemical products made directly from ores of valuable metals, and (3) chemical products that pass through several metallurgical and chemical processes in their preparation from the original ores.

Natural mineral paints.—In 1908 the total production of the natural pigments—ochre, amber, sienna, metallic paints, mortar colours, slate and shale—reported to the Survey amounted to 49,853 short tons, valued at \$536,544, as compared with 48,546 short tons, valued at \$530,486 in 1907. The following table shows the production of these mineral pigments in 1907 and 1908:

	1907.		1908.	
	Tons.	Value.	Tons.	Value.
		\$		\$
Ochre	16,971	164,742	17,019	156,360
Amber and sienna	730	19,309	2,756	70,996
Metallic paint	16,225	195,176	16,224	182,007
Mortar colours	10,490	110,719	9,026	86,967
Slate and shale, ground ..	4,130	40,540	4,828	40,220

The imports of ochre in 1908 were as follows:—Crude, 584,129 pounds, valued at \$4,954; dry, 8,663,537 pounds, valued at \$69,815; ground in oil, 6,094 pounds, valued at \$307; total, 9,253,760 pounds, valued at \$75,076. The imports of amber in 1908 were as follows:—Dry, 2,391,153 pounds, valued at \$19,461; ground in oil, 15,556 pounds, valued at \$803; total, 2,406,709 pounds, valued at \$20,264. Imports of sienna in 1908 were as follows:—Dry, 1,756,237 pounds, valued at \$28,407; ground in oil, 7,621 pounds, valued at \$458; total, 1,763,894 pounds, valued at \$28,865.

Metallic paint and mortar colours.—Metallic paint and mortar colours are red and brown iron oxides, produced either by grinding the impure mineral found in the natural state, or by roasting impure iron carbonate. The production of metallic paint and mortar colours in 1908 as reported to the survey, amounted to 25,250 short tons, valued at \$268,968, a slight decrease in quantity from the 1907 production of 26,715 short tons, but a large decrease in value as compared with \$305,895, the total value for 1907.

Slate and shale.—Slate and shale were ground for use as pigments in 1908 principally in Pennsylvania and New Jersey. The following table gives the production of slate and shale ground for pigment from 1905 to 1908, inclusive:—

	Tons.	Value.
		\$
1905	5,181	44,108
1906	5,481	40,540
1907	5,130	40,540
1908	4,828	40,220

Paint ore deposits.—The paint ore deposits near Lehigh Gap, Pa., have been extensively developed during the past year or two. The deposits are situated in the southern part of Carbon County, Pa., seven miles below Mauch Chunk, and extend in a general east-west direction for about 20 miles. The paint bed is a sedimentary

formation of Devonian age lying between the Oriskany and Hamilton formations. It has been traced west to Germans, five miles west of Lehigh River, and eastward to Little Gap. The area in which the deposit lies is a narrow strip from one-half mile to two miles wide. The paint ore in this vicinity consists principally of carbonate of iron. The bed varies in thickness, being in some places one and one-half to two feet thick; rarely it is found as thick as four feet; in many places its thickness is but a few inches, and in others it cannot be found.

The following is an average analysis of the crude ore:—Iron, 33.00 per cent.; manganese, 0.01 per cent.; silica, 25.00 per cent.; carbon dioxide, 25.00 per cent. There are in addition small quantities of magnesia, sulphur, and phosphorus present. The specific gravity of the ore varies from 3.2 to nearly 4. The treatment of the ore in this region consists of calcining and grinding to a fine powder, in which state it is sold dry to be mixed with oil. At the mills the ore is broken up with sledges into six-inch pieces and is ready for calcination. This was formerly carried on in stone kilns, but these are being replaced by more modern steel-jacketed kilns. Certain typical kilns are of brick construction with sheet-steel sheathing twenty-five feet high and ten feet in diameter. There are two fireplaces, one on each side, making the width of the kiln at the bottom eighteen feet. Cord wood is used as fuel and the average temperature obtained is 500° F. The run lasts twenty-four hours and every twelve hours ten tons of calcined ore is drawn off at the bottom, a corresponding quantity of raw ore being charged at the top. The calcined material is very compact and of a dark reddish-brown colour. It is of the same composition as the finished product, the rest of the process consisting simply of grinding. The loss during calcination is from 20 to 25 per cent. The product is ground to buckwheat size by gyratory crushers, after which it is ground very fine by three thirty-six-inch horizontal buhr mills and three vertical mills. More of this metallic paint is used for freight cars than for any other purpose. It is recommended that seven pounds of paint be mixed with one gallon of boiled linseed oil; the mixture will be sufficient for one coat over an area of 500 square feet. It is used also for painting structural steel, tin roofing, tanks, boats, and as a filling in oilcloth and linoleum.

Pigments made direct from ores.—The pigments made direct from ores or valuable metals are zinc oxide, leaded zinc oxide, zinc lead, sublimed white lead, and sublimed blue lead. The ores utilised in making these pigments are the franklinite ores of New Jersey, the sphalerite and galena ores of the Mississippi Valley (mined in the Plattville district of Wisconsin and the Joplin district of Missouri, Kansas, and Oklahoma), and the sulphide, carbonate, and silicate ores of zinc and lead produced in Colorado and New Mexico.

The production of zinc oxide in 1908 as reported to the Survey was 56,292 short tons, valued at \$5,072,460, as compared with 71,784 short tons, valued at \$6,490,660, in 1907.

The production of zinc lead, including leaded zinc oxide, in 1908 was 8,430 short tons, valued at \$778,200, as compared with 13,086 short tons, valued at \$1,286,440, in 1907.

In 1908 there were produced in the United States, 9,100 short tons of sublimed white lead, valued at \$973,700, an average value of \$107 per ton; in 1907 the production amounted to 8700 short tons, valued at \$1,026,600, an average value of \$118 per ton.

There were 1311 short tons of sublimed blue lead produced in 1908, valued at \$121,923, as compared with 1211 short tons, valued at \$135,632, in 1907. The average value per ton in 1907 was \$112; in 1908 it was \$93.

The imports of zinc oxide in 1908 were as follows:—Dry, 4,635,101 pounds, valued at \$262,876; in oil, 210,166 pounds, valued at \$10,798; total, 4,845,267 pounds, valued at \$279,674.

Chemically manufactured pigments.—Under this heading are grouped the lead pigments made from pig lead and lead compounds, and such minor pigments as lithopone and Venetian red. Much of the material now sold as Venetian red, however, instead of being precipitated from ferrous sulphate and calcium hydroxide, is made by

calcining a mixture of ferrous sulphate and *terra alba* and also by grinding natural red iron oxide with a white base, such as ground oyster shells.

The production of basic carbonate (corroded) white lead, as reported to the Survey, in 1908 was 132,588 short tons, valued at \$15,891,001. Of this total 101,109 short tons were sold in oil, valued at \$12,552,771, and 31,479 short tons were reported sold dry, valued at \$3,338,830. The sales for 1908 represented a net gain over those for 1907 of 5337 short tons in quantity, but a net decrease of \$556,723 in value, showing a general decrease from the average value \$129.25 per ton in 1907 to \$119.85 per ton in 1908.

The production of red lead fell from 20,078 short tons, valued at \$2,802,454, in 1905 to 16,720 short tons, valued at \$2,065,202, in 1908. The average value per ton decreased from \$139.57 in 1907 to \$123.52 in 1908.

In 1908 15,542 short tons of litharge were produced, valued at \$1,887,506, as compared with 20,838 short tons, valued at \$2,854,987, in 1907. This represents a fall from the average value per ton, \$137, in 1907 to \$121.45 in 1908.

Orange mineral likewise showed a reduction in output, there being 397 short tons produced in 1908, valued at \$65,498, as compared with 669 short tons, valued at \$129,410, in 1907.

The production of lithopone in 1908 was reported as 8292 short tons, valued at \$639,483, as compared with 10,275 short tons, valued at \$750,350, in 1907. In the case of lithopone the value per ton apparently increased from \$73.03 in 1907 to \$77.12 in 1908, or \$4.09.

The production of Venetian red in 1908 amounted to 8825 short tons, valued at \$159,650, as compared with 7566 short tons, valued at \$134,167 in 1907. The average value per ton apparently increased from \$17.73 in 1907 to \$18.09 in 1908.

The following table gives the quantity and value of the imports of corroded white lead, red lead, litharge, orange mineral, and Venetian red in 1908:—

	Pounds.	Value.
		\$
Corroded white lead	540,311	30,452
Red lead	645,073	28,153
Litharge	96,184	3,327
Orange mineral	489,407	26,445
Venetian red	3,113,858	25,745

Turpentine oil and its substitutes. J. Marcusson. Chem.-Zeit., 1909, 33, 966—967; 978—979; and 985—987.

THE author discusses different methods which have been published for the detection of petroleum, pine oil, rosin spirit, carbon tetrachloride, regenerated turpentine, etc., in oil of turpentine. Determinations of the refractive index and specific gravity of the fractions obtained on distilling a sample of oil of turpentine afford useful data for detecting the presence of petroleum, benzene, xylene, and naphtha in the sample. Whilst the sulphuric acid test (this J., 1905, 562) is useful in some cases, it is not altogether reliable. Carbon tetrachloride may be detected by testing the sample for chlorine, and regenerated turpentine (the turpentine recovered in the manufacture of synthetic camphor) is characterised by its high boiling point; genuine oil of turpentine distils at from 155° to 175° C., about 80 per cent. coming over below 165° C., whilst regenerated turpentine only begins to distil at a temperature of 170° C.

Burton's nitric acid test for petroleum.—The author describes a modification of Burton's nitric acid test for the detection and determination of petroleum in oil of turpen-

time. It consists in adding 10 c.c. of the sample to 30 c.c. of fuming nitric acid previously cooled to —10° C. and contained in a bulb-tube the neck of which is graduated. The addition is made drop by drop so that the temperature of the mixture does not exceed —10° C. After the lapse of 30 minutes, concentrated nitric acid cooled to —10° C. is added so as to bring the undissolved portion of the oil into the neck of the bulb, and its volume is read off. The acid layer is then separated, diluted with 150 c.c. of water, the mixture is heated on a water-bath, cooled, and shaken out with ether. The ethereal solution is washed first with water, then with caustic potash, and evaporated. The residue obtained is weighed and its weight divided by 1.15 to give its volume in c.c. This volume added to that read off directly in the graduated tube, gives the quantity (by volume) of petroleum in the 10 c.c. of the sample.—W. P. S.

Japan; Duty on concentrated — in Australia. Board of Trade J., Sept. 30, 1909. [T.R.]

A STATUTORY RULE (No. 94 of 1909) provides, with effect from July 22 last, that the following shall be the standard according to which duty shall be charged on the under-mentioned "japan" on importation into the Australian Commonwealth: Concentrated japan of a consistency that by the addition of an equal weight of turpentine produces a japan of ordinary consistency—one gallon of the concentrated japan to be deemed equal to two gallons of the japan of ordinary consistency.

The rates of duty leviable on japan are 2s. per gallon under the British Preferential Tariff, and 2s. 6d. per gallon under the General Tariff.

PATENT.

Rosin; Process for the purification of — H. T. Yaryan, Toledo, Ohio. U.S. Pat. 934,257, Sept. 14, 1909.

THE rosin is dissolved in a liquid hydrocarbon and the solution is agitated after the addition of cold water; the mixture is then allowed to separate into various layers which are separated from each other.—W. P. S.

(C.)—INDIA-RUBBER, &c.

Rubber content of Lactuca viminea, Presl. V. Guafé and K. Linsbauer. Z. landw. Vers.-Wesen Oesterr., 1909, 12, 126—141. Chem. Zentr., 1909, 2, 1059.

Lactuca viminea, a biennial plant of the order *Compositae*, which is found in Austria, yields a latex which contains an amount of rubber corresponding to about 0.5 per cent. of pure caoutchouc on the weight of the dry substance of the plant. It thus yields more rubber than *Hevea brasiliensis*, from which, according to Alexander and Bing (*Tropenpflanzer*, 12, 57), only about 0.3 per cent. is obtainable. In searching for new rubber-yielding plants, it would appear desirable to pay greater attention to plants of the order *Compositae*, to which, besides *L. viminea*, the Mexican guayule plant also belongs. For the determination of the caoutchouc content of *L. viminea*, the plant, at the period of its maximum growth, was dried, extracted with petroleum ether, the extract treated with 10 per cent. alcoholic caustic potash to remove saponifiable matter, and then extracted with carbon bisulphide. From the evaporation residue of the carbon bisulphide extract, the resin was removed by means of acetone, and then the pure caoutchouc was determined by Harries and Weber's method, and Fendler and Kuhn's modification of Budde's method.—A. S.

XIV.—TANNING, LEATHER, GLUE, SIZE.

Zeuthen's method [of washing hide powder]; Examination of —. J. Paessler. *Collegium*, 1909, 305—312.

THE author considers that the method of washing chromed hide powder proposed by Zeuthen (*Collegium* 1908, 366) is quicker and more convenient than the official method. In order to obtain the same analytical results by the official method and by Zeuthen's method, he proposes to modify the latter so that the same amount of dry hide powder (6.5 grms.) is used in each case. To wash this quantity of dry chromed hide powder by Zeuthen's method, larger filter-bells (3 by 8.5 cm.) are employed. Comparative results of non-tannin determinations are given by the official method, and by Zeuthen's method with 20 c.c. and with 35 c.c. of water in the wet powder. The results by the two methods differ on the average by 0.4 per cent., Zeuthen's method giving the lower values for non-tannins. Further results with the use of only 20 c.c. of water in the wet powder by both methods show a very small average difference. Certain tanning materials, however, show differences up to 1 per cent., the official method giving sometimes the higher and sometimes the lower results. The author also gives 3 analyses to show that his dry chromed powder gives the same results by Zeuthen's method whether it be 2½ years, 2 years, or only a few days old.—H. G. B.

Azelaic acid as a product of oxidation of keratin. T. Lissizin. *Z. physiol. Chem.*, 1909, 62, 226—228.

THE author has investigated the products of oxidation of keratin (horn shavings) by potassium permanganate. The most favourable conditions were, 1 part by weight of potassium permanganate, to 8—9 parts of keratin, the process being as follows:—300 grms. of horn shavings were treated with 35 grms. of potassium permanganate dissolved in 6 litres of water. The mixture was shaken for 4 to 6 days by a shaking machine until the solution was quite colourless. It was then filtered, acidified with dilute sulphuric acid, and after concentration, extracted with ether. The residue left on evaporation of the ether, was purified by recrystallisation, and was identified as azelaic acid. In order to decide the question whether the azelaic acid was formed by oxidation of fatty bodies or of other substances accompanying the keratin, the author carried out experiments on fat-free and purified horn shavings. The yield obtained was lower, but he concludes that azelaic acid is in effect a new oxidation product of keratin.—W. N. B.

Gelatinous substances; Formation of oxalic acid from —. W. Sadikow. *J. Russ. Phys.-Chem. Ges.*, 1909, 41, 641—651. *Chem. Zentr.*, 1909, 2, 1126.

By the action of nitric acid of sp. gr. 1.4 on thioglutan (see this J., 1907, 105), more or less oxalic acid is formed, according to the conditions. Glutin gives oxalic acid only if the oxidation is effected in presence of calcium salts which prevent decomposition of the oxalic acid by the nitric acid. Tendocollagen also yields oxalic acid on oxidation with nitric acid. On fusion with caustic potash at 240° C. for 6 hours, glutin yielded 39.17 per cent. of oxalic acid, reckoned on the carbon of the glutin. Whilst carbohydrates yield hydrogen on fusion with caustic potash, proteid adhesive substances yield oxalic acid and ammonia.—A. S.

PATENTS.

Decolorising product composed of sodium hydrosulphite and zinc dust. Fr. Pat. 401,000. See VII.

Paper to be used as a substitute for leather. Eng. Pat. 20,616. See XIX.

XV.—MANURES, &c.

Calcium phosphate; Manurial experiments with precipitated —. H. C. Söderbaum. *Z. Landw. Vers.-Wes.*, 1908, 506; *Biedermann's Zentrabl.*, 1909, 38, 585—587.

EXPERIMENTS have been made in Stockholm for some years with electrolytically precipitated calcium phosphate to test its manurial value towards oats and peas in comparison with superphosphate. One commercial preparation consisted mainly of tricalcium phosphate containing 34.3 per cent. of total, and 5.6 per cent. of citrate-soluble phosphoric acid; a second showed 39.9 per cent. of total, and 33.5 per cent. of citrate-soluble phosphoric acid, and was mainly dicalcium phosphate. The action of the dicalcium phosphate was as great and as continuous as that of superphosphate, and the assimilative power of the phosphoric acid was not lowered by the addition of large quantities of calcium carbonate. The tricalcium phosphate was much less valuable as a manure, and its activity was very markedly decreased on the addition of increasing quantities of chalk.—E. F. A.

Silver cyanamide [and determination of cyanamide in commercial products]. H. R. Ellis. *Chem. News*, 1909, 100, 154—155.

THE author criticises Perotti's method for the determination of cyanamide (this J., 1905, 1129) and recommends the following process:—20 c.c. of a solution of the substance, of about *N*/10 strength, are added to about 40 c.c. of *N*/10 silver nitrate and 10 c.c. of *N*/1 nitric acid; the silver cyanide thus precipitated, is filtered off and washed, the filtrate and washings being received in 20 c.c. of *N*/1 ammonium hydroxide, and the solution is warmed; silver cyanamide is precipitated, and, after washing, it is treated on the filter with nitric acid (1:5), the residue is washed, and the silver determined by Volhard's method in the filtrate and washings. The silver cyanide precipitate is also dissolved in nitric acid and the silver determined by *N*/50 ammonium thiocyanate. From the weight of silver in each case the percentage of cyanide and cyanamide can be calculated. This process is applicable to the analysis of commercial sodium cyanamide. In the case of "nitrolim," 1—2 grms. of the very finely powdered substance is shaken with water and filtered, and washed until no precipitate is given with ammoniacal silver nitrate; the volume is made up to 500 c.c., and 20 c.c. of this solution are added to an excess of *N*/10 silver nitrate (about 30 c.c.) and 20 c.c. of *N*/1 ammonium hydroxide; the precipitated silver cyanamide is washed with warm water and the silver determined as above, any silver sulphide or chloride remaining on the filter paper, undissolved by the nitric acid. Silver cyanamide, when rapidly heated, explodes violently; the decomposition is represented by the equation: $2\text{Ag}_2\text{CN}_2 = 4\text{Ag} + \text{C}_2\text{N}_2 + \text{N}_2$.—F. SONN.

Cape Colony: Proposed regulations under Fertilisers Act, 1907. Board of Trade J., Oct. 14, 1909. [T.R.]

THE Government of Cape Colony have approved of the issue of certain additional regulations under the Fertilisers Act No. 20 of 1907, with effect from 1st January next.

These regulations are briefly as follows:—1. The registered brand will have to be legibly marked on the receptacle containing the fertiliser. 2. Brands or names of fertilisers which contain a numerical indication of the proportion of any constituent of the fertiliser as an integral portion of the brand will not be accepted for registration unless amended in that respect. 3. The practice of using a figure to represent any constituent of a fertiliser in any advertisement, invoice, or label is forbidden, unless such figure is accompanied by the name of the constituent so represented, and further the constituent so alluded to must be expressed in the manner set forth in the regulations. 4. In the case of superphosphates (excepting double or basic superphosphates) these will, in future, be

graded according to their percentage of phosphoric oxide as under, and the grade will have to be distinctly marked on the receptacle:

Under 12 per cent.	Below strength.
12 per cent. to 13 per cent.	Low grade.
Above 13 per cent. to 15 per cent.	Medium grade.
Above 15 per cent. to 17 per cent.	Medium high grade.
Above 17 per cent.	High grade.

The above marking will, in addition, be required to be accompanied by a figure indicating the minimum percentage contained in the particular consignment, *e.g.*, "medium grade" comprises a range of about 13 per cent. to 15 per cent. It would, therefore, be necessary to mark a receptacle "medium grade 13 per cent.," or 14 per cent., or 15 per cent., according to what the minimum percentage actually was. This is the only instance in which a numeral may be used unaccompanied by the name of the constituent referred to and special provision has been made in the regulations accordingly. The use of the term "guano" is forbidden to be applied to any substance other than the nitrogenous excreta of birds or bats and fish or whale fertiliser. In the case of the last three mentioned it must be preceded by the term "bat," "fish," or "whale" respectively; used by itself it will signify only the nitrogenous excreta of birds. So-called phosphatic guanos (*e.g.*, those from which the nitrogen has disappeared), may not be sold as "guano," but as "guano phosphate." 5. The sale of bone-meal or bone-dust which is not sufficiently fine to permit 80 per cent. thereof to pass through a sieve of 8 meshes to the linear inch is forbidden. 6. The sale of basic slag, Thomas phosphate, or Thomas slag, which is not sufficiently fine to admit of 75 per cent. thereof passing through a standard wire sieve of 100 meshes to the linear inch is also forbidden.

Determination of phosphoric acid. Crete. See XXIII. Inorganic Quantitative.

PATENT.

Artificial nitrate for use as manure; Process of manufacture of —. A. Montbaron and A. Ducommun-Müller. Fr. Pat. 400,895, March 16, 1909. Under Int. Conv., Feb. 27, 1909.

AMMONIACAL liquor, extracted from peat, is fermented, and nitric acid, lime, and impure salt are added; nitrification is then brought about by a further fermentation, and the product is crystallised for use as a manure. As an example, for 1 ton of product, 320 kilos. of the ammoniacal liquor, 300 of lime, 300 of impure salt, and 80 of nitric acid are said to give good results.—F. SOBY.

XVI.—SUGAR, STARCH, GUM, &c.

PATENTS.

Crystalloids from parts of plants and other organised substances [sugar from beetroots]; Process for effecting the fixation of —. Soc. Egyetemes Kísérletező Intezet, Vegyészeti, Orvosi és Gyógyszerészeti Laboratorium Részvénytársaság. Fr. Pat. 400,964, March 13, 1909.

SULPHUROUS acid, or other acid, is employed as a catalytic agent in the extraction of crystalloids from organic substances, for instance, in the extraction of sugar from beetroots. The extraction is carried out at the ordinary temperature, and the extraction battery is so arranged that the weak sugar solution containing sulphurous acid is allowed to act on a fresh charge of beetroots which absorbs the acid from the sugar solution. The extracted beetroots are treated with water and the acid solution obtained is employed as an extractive solution for a fresh charge. It is only necessary to add a little sulphurous acid from time to time to replace the portion which is unavoidably lost.

—W. P. S.

Juice extraction by diffusion; Continuous —. K. Philipp. Magdeburg, Germany. U.S. Pat. 934,349, Sept. 14, 1909.

XVII.—BREWING, WINES, SPIRITS, &c.

Nitrogen content of barley; Relation between the — and the extract yielded by the malt. J. Fries. Z. ges. Brauw., 1909, 32, 500–503.

THE nitrogen in a hundred samples of barley of 1908 harvest was determined and calculated into terms of protein. The values so obtained were plotted against the extract yield of the corresponding malts. Six different kinds of mid-European barleys were examined and in each the extract was found to decrease fairly regularly with the increase in protein; exceptions were usually to be accounted for by differences in the kilning of the malt. Co-ordinating the average protein content of the six kinds of barley and the average extract yielded by their malts, the author claims that they vary in almost exactly inverse ratio.—R. L. S.

Alcoholic fermentation; Decomposition of sugar by —. E. Buchner. Ges. Deutscher Naturforscher u. Aerzte, Sept., 1909. Chem.-Zeit., 1909, 33, 1001.

EXPERIMENTS made by the author in conjunction with J. Meisenheimer show that, under normal conditions, lactic acid is neither formed from sugar, nor fermented, by the action of living yeast, a pure culture of Race 792 being employed. These results are in accord with those obtained from the study of cell-free fermentation by expressed yeast-juice and with Sclater's conclusion (this J., 1906, 227) that lactic acid is not an intermediate product in the fermentation of sugar. The author has investigated the behaviour towards yeast and yeast-juice of methylglyoxal, glyceraldehyde, and dihydroxyacetone. Whilst the first of these compounds undergoes virtually no fermentation, glyceraldehyde is slowly and dihydroxyacetone fairly rapidly fermented. A two per cent. solution of dihydroxyacetone yields besides alcohol, as much carbon dioxide in 5 days as is given by a dextrose solution of the same concentration. It remains to be ascertained whether dihydroxyacetone is actually formed during alcoholic fermentation. (See also this J., 1909, 494).

—T. H. P.

Molasses washes; Fermentation of —. L. Neustadt and B. Ehrenfreund. Chem.-Zeit., 1909, 33, 1056–1057.

IN attempting to determine the residual sugar in fermented [beet] molasses washes by polarimetric examination, the authors found that these washes were invariably dextro-rotatory (0.1°–0.2° in 200 mm. tube at 20° C.). Polarimetric tests at frequent intervals during the fermentation of a molasses wash showed that the dextro-rotation first falls gradually to *nil*, when there is a period of increasing levo-rotation, followed by a fall and a further rise, after which the levo-rotation falls gradually to *nil*; in the final stage there is a slight dextro-rotation which, at the end, remains constant at about 0.2°. The detailed results are shown in the following table:—

Time.	Density.	Polarisation.	Time.	Density.	Polarisation.
hrs. mins.	° Balling.		hrs. mins.	° Balling.	
1 45	13.7	+2.6	8 0	9.1	—1.4°
2 0	13.6	+2.0	9 0	8.3	—1.1°
2 15	13.4	+1.7	10 0	7.6	—0.9°
2 30	13.3	+1.5	11 0	7.0	—0.7°
2 45	13.1	+1.0	12 0	6.6	—0.5°
3 0	12.9	+0.7	1 0	6.2	—0.3°
3 15	12.8	+0.4	2 0	6.0	—0.1°
3 30	12.6	+0.2	3 0	5.9	0
3 45	12.4	0	4 0	5.8	+0.1°
4 0	12.2	—0.3	5 0	5.7	+0.2°
4 15	12.0	—0.6	6 0	5.6	+0.4°
1 30	11.8	—0.8	7 0	5.5	+0.5°
1 45	11.6	—0.9	8 0	5.4	+0.6°
5 0	11.4	—1.1	9 0	5.3	+0.3°
5 15	11.2	—1.4	10 0	5.3	+0.2°
5 45	11.0	—1.3	11 0	5.3	+0.2°
6 15	10.6	—1.2	1 0	5.3	+0.2°
7 0	10.0	—1.5	—	—	—

The results are interpreted as follows:—From the beginning until the density falls to 11.2° Balling, sucrose is inverted and mainly dextrose is fermented; at the latter point the inversion of the sucrose is complete and the fermentation of the levulose becomes noticeable. The increase of lavo-rotation between 10.6° and 9.1° Balling is due to the hydrolysis of raffinose into levulose and melibiose; the further hydrolysis of melibiose into dextrose and galactose has practically no effect on the rotation. At 5.4° Balling the fermentation of the levulose is complete, and the final stage of the process consists in the fermentation of galactose, which proceeds very slowly. The authors consider that the final degree of attenuation of the fermented wash can be judged with sufficient accuracy by means of polarimetric examination.—A. S.

French alcohol statistics for 1908. Z. Spiritusind., 1909, 32, 453.

ACCORDING to the official statistics the production of spirit (reckoned as absolute alcohol) in France was 55,862,040 galls. in 1908, as compared with 55,350,970 galls. in 1907. The consumption of tax-free alcohol for industrial and scientific purposes in the two years is shown in the following table:—

	1908.	1907.
	galls.	galls.
For lighting and heating, etc.....	9,744,883	8,831,072
" preparation of varnishes	265,309	294,626
" polishes	24,585	26,192
" plastic substances	468,813	377,097
" fur industry	5282	6537
" preparation of tinctures and colours	25,245	13,910
" rennet	3456	3918
" collodion	7902	16,508
" chloroform	4270	2223
" chloral	10,785	3412
" tannin	20,910	11,225
" chem. and pharm. prods.	153,476	228,904
" scientific purposes	12,920	28,657
" preparation of ether and explosives	3,044,995	3,226,050
" vinegar	1,053,421	1,062,577
Totals	14,846,252	14,132,908

In 1900 the consumption of tax-free alcohol was 6,068,773 gallons, and in 1892, 3,470,251 gallons.—A. S.

Cider apples; Use of an oxidising lime solution [bleaching powder] for washing:—rapid defecation of the must, and pure fermentation. H. Alliot and G. Gimel. Comptes rend., 1909, 149, 532—534.

CIDER apples should be washed with water containing 28 to 42 grains of bleaching powder per gallon (40—60 grms. per hectolitre) in order to clean the fruit and destroy bacteria, pathological and others, with which they may be contaminated. Juice of fruit treated in this way defecates well and clarifies quickly; the pectinous substances always separate as a brown head. Bleaching powder has a stimulating influence on *Saccharomyces mali*, but retards the activity of bacteria, thus assisting very materially the use of pure races of selected yeasts. Analytically the cider prepared from apples washed with bleaching powder contains slightly more chlorides.

Flours; Examination of — on the basis of their content of catalase. P. Liechti. Chem.-Zeit., 1909, 33, 1057.

ACCORDING to the author the quality of a flour can be satisfactorily judged from its capacity of liberating oxygen from hydrogen peroxide, which depends on its content of catalase. In the grain the catalase is present in the husk (bran) and the embryo, that is, in those portions which are, as far as possible, removed in the preparation of bread-making flours. Some experimental results obtained are given in the following table, the figures representing the pressure of the oxygen evolved in cm. of mercury.

Panary fermentation. Relation between the extent of fermentation and the starch degradation. M. P. Neumann and K. Mohs. Z. ges. Getreidewesen, 1909, 1, 89; Biedermann's Zentrabl., 1909, 38, 633—635.

THE author discusses the rôle played by carbohydrates in panary fermentation and states that the diastatic activity of the flour is sufficient not only to produce the sugared in fermentation, but such a quantity, that after two hours, an amount of sugar is found in the dough equal to that originally present.—E. F. A.

Casein in cow's milk; Volumetric method for the determination of — E. B. Hart. J. Biol. Chem., 1909, 6, 445—451.

CASEIN which has been precipitated from milk by the action of acids, is capable, after the removal of the excess of acid by long-continued washing, of combining with a definite proportional quantity of alkali to yield a compound which is neutral to phenolphthalein. The method proposed is based on these facts. Preliminary experiments with casein prepared by Hammarsten's method from mixed milks and from the milk of typical breeds of cows showed that each 0.1 c.c. of N/10 alkali solution is equivalent to 0.0108 grm. of casein, this being the mean of twenty determinations, the results of which varied between 0.0102 and 0.0113 grm. 10.5 c.c. of the milk are placed in an Erlenmeyer flask, 75 c.c. of cold water are added, and from 1 to 1.5 c.c. of 10 per cent. acetic acid. The flask is given a vigorous rotary motion and the precipitate is then collected on a filter. As the casein accumulates on the filter, the mass is loosened by means of a jet of cold water, so that retardation of the filtration does not take place. The particles of casein adhering to the sides of the flask need not be removed, but they must be thoroughly washed, the precipitate and filter being also washed with at least 300 c.c. of water to insure removal of all acid. If the temperature has been kept below 20° C., and the right amount of acid used for the precipitation, the filtrate will be perfectly clear. The precipitate, together with the filter, is now returned to the flask, about 80 c.c. of

water free from carbon dioxide are added, then a few drops of phenolphthalein and 10 c.c. of *N*/10 potassium hydroxide solution. The flask is closed with a rubber stopper and shaken until all the particles of casein have dissolved. When solution has taken place, the stopper is rinsed with water and the solution is immediately titrated with *N*/10 acid until the red coloration disappears. It is imperative that a control determination be made parallel with the determination proper. The quantity found in the control determination (0.2—0.3 c.c.) is added to the number of c.c. of acid used in the titration and the difference between the corrected acid reading and the 10 c.c. of alkali used gives directly the percentage quantity of casein in the milk.—W. P. S.

Casein; Hydrolysis of —, and detection of the mono-aminoacids formed thereby. R. Engeland. Ber., 1909, 42, 2962—2969.

WHILST it is easy to identify leucine, tyrosine, and glutamic acid, this is not the case with the other easily soluble monoaminoacids produced by the hydrolysis of casein and other proteins. The method proposed by the author consists in the exhaustive methylation of these aminoacids by means of methyl iodide and a solution of potassium hydroxide in methyl alcohol, whereby they are converted into betaines, which can be easily identified by the varying solubility of their double salts with mercury, platinum, or gold chlorides. By applying this method to the products of hydrolysis of casein with hydrochloric acid of sp. gr. 1.19, after separating glutamic acid, tyrosine, and leucine in the usual manner, the author identified *l*-pyrrolidine-carboxylic acid in the form of *N*-methylglycine acid, aminovaleric acid as trimethylaminovaleric acid, glycocoll as betaine, and alanine as homobetaine.—A. S.

Proteins; The leucine fraction of —. P. A. Levene and D. Van Slyke. J. Biol. Chem. 1909, 6, 391—418.

THIS paper deals more particularly with the separation of *l*-leucine and *d*-isoleucine from *d*-valine. The authors find that leucine and isoleucine are precipitated quantitatively as the normal lead salt, $\text{Pb}(\text{C}_6\text{H}_{12}\text{O}_2\text{N})_2$, when lead acetate solution containing 1 gram.-mol. per litre, in quantity slightly more than equivalent to the leucine and isoleucine present, is added to a hot ammoniacal solution of the substances. The valine is recovered from the filtrate of the lead-leucine precipitate by precipitating the excess of lead with hydrogen sulphide, and evaporating the filtrate from the lead sulphide to dryness. The valine is then extracted from the residue with a mixture of alcohol and ether (3:1). The relative proportions of the leucine isomerides may be determined polarimetrically by the optical rotation of their mixture in 20 per cent. hydrochloric acid; and the isomerides may be separated by Ehrlich's method of extracting their copper salts with methyl alcohol. Isoleucine preparations from casein and edestine showed, after repeated purification by means of the copper and lead salts, specific rotations of $[\alpha]_D = +37.35^\circ$ and $+37.44^\circ$. The value $[\alpha]_D = +37.4^\circ$ doubtless more nearly expresses the rotation of pure natural isoleucine than does $[\alpha]_D = +36.8^\circ$, the value found by Ehrlich, who had less complete means of purifying the substance. Fischer and Warburg found the specific rotation of *l*-leucine to be $[\alpha]_D = +15.6^\circ$.—W. P. S.

Casein and edestine; The leucine fraction in —. P. A. Levene and D. D. Van Slyke. J. Biol. Chem., 1909, 6, 419—430.

THE authors have investigated the leucine fraction obtained from casein and edestine (from flax-seed), the process described in the preceding abstract being employed after the baryta method had been used for the separation of the esterified substances. In the case of casein, the leucine fraction, amounting to 16.04 per cent., was found to consist of leucine, 7.92; isoleucine, 1.43; and valine, 6.69 per cent. The leucine fraction of edestine amounted to 13.7 per cent. and consisted of leucine and isoleucine, 8.1; and valine, 5.6 per cent. These figures are considerably higher than those obtained by other workers, and the authors consider that the figures for the leucine fraction in most protein hydrolyses hitherto published are in need of revision.—W. P. S.

Eggs; The cholesterol-content of — as a basis for the valuation of pastry. H. Cappenberg. Chem.-Zeit., 1909, 33, 985.

THE average egg contains about 0.36 per cent. of cholesterol and a determination of this constituent affords a means of ascertaining the quantity of egg-substance in articles of food such as pastry, etc. A quantity of 500 grms. of the sample is extracted with ether, the solution is filtered, and the ether is evaporated. The residue obtained is saponified, the soap solution is evaporated to dryness and this residue is also extracted with ether. The ether extract is filtered, evaporated, the residue is dissolved in hot methyl alcohol, the solution is filtered while hot, and, after the addition of 20 per cent. of water, it is evaporated until crystallisation commences. The mixture is then cooled to a temperature of 0°C ., the crystals of cholesterol are collected on a filter, washed first with 50 per cent. methyl alcohol, then with hot water, dried for 3 hours at 100°C ., and weighed.—W. P. S.

PATENTS.

Flour; Milling of —. [Preventing evaporation of water]. H. Simon, Ltd., Manchester. From L. M. Thomas, Strassburg, Germany. Eng. Pat. 11,904, June 1, 1908.

TO prevent evaporation of water from wheaten flour during the milling operations, air saturated with water vapour is admitted to the milling machinery; the moistened air may be introduced into the whole of the rooms of the mill if desired. The air is saturated by bubbling it through water or by spraying water or injecting steam into it. The temperature of the air may be raised above the normal and it is advantageous to heat the air passing from the rollers before it enters the filter dust collectors.

PATENTS.

Sewage; Method or process for the recovery of the useful constituents of —. M. F. Purcell and J. H. Ryan. Dublin, and C. J. Polglase, Falmouth. Eng. Pat. 18,199, Aug. 31, 1908.

THE process relates to the recovery of ammonia, gas, heavy oils, etc., and consists in submitting the sewage-sludge to destructive distillation. The sludge is pressed to remove superfluous moisture and the cake, with or without the addition of lime or sodium hydroxide, is introduced into a retort similar to those used in the distillation of shale. Coal or other fuel is introduced along with the first charge, the subsequent charges being introduced continuously, so as to be self-firing. When the charge is alight, steam, either wet, dry, or superheated, is injected under pressure and the products of distillation are conducted to a tank containing water. The ammonia is absorbed by the water, the oils form a layer on the surface of the water, and the combustible gases are then conducted to a gasometer or other receptacle. Means are provided for withdrawing the oils and ammonia solution from the tank, the latter solution being afterwards treated with sulphuric acid and the ammonium sulphate recovered by crystallisation. The retort residue is withdrawn as required, and may be used for making cement, or for other purposes. (Reference is directed to Eng. Pats. 629 of 1885, 14,253 of 1890, 1567 of 1892, 3272 of 1895, 23,562 of 1898, 21,921 of 1899, and 15,720 of 1900; this J., 1900, 67; 1901, 830.)—W. P. S.

Sewage water; Apparatus for purifying —. P. Koch, Villingen, Germany. Eng. Pat. 23,668, Nov. 5, 1908.

THE apparatus consists essentially of a settling tank and an oxidising or filtering tank. The former is cylindrical in shape and is provided with an inner cylinder the walls of which are perforated in parts. The sewage is introduced into the inner cylinder and flows through the perforations into the space between the two cylinders. Sedimentation takes place here and the lighter components of the sewage rise to the surface and quickly decompose, an outlet being provided for the gases which are formed. The liquid portion of the sewage then flows from the top of the tank through a pipe, and is distributed over the surface of a filter-bed composed of "the oxidising material," consisting of gravel and charcoal, arranged in the second tank. A ventilating space is provided below this filter and air is supplied through a perforated pipe, through holes in the side of the tank, and through perforations at the bottom of the tank. One or more of these oxidising tanks may be employed in connection with the settling tank. The apparatus as described and arranged, is claimed.—W. P. S.

Sewage, etc.; Apparatus for dissolving and nitrifying the solid matters in —. C. Didelon and A. Braut. Fr. Pat. 400,981, June 29, 1908.

THE apparatus consists of two tanks, one closed and the other open to the air. The sewage is introduced into the top of the closed chamber, which is divided into two compartments by means of a perforated partition, the crude sewage falling into one of the compartments. When anaërobic fermentation has taken place and the solid matters have been dissolved, the liquid portion of the sewage, passing through the perforated partition, is conducted through a pipe into the lower part of the second chamber. This is also divided into two parts by a vertical partition reaching nearly to the top. The sewage rises in one of the compartments, passes through a bed of slag or cinders contained in the space between two horizontal perforated partition-plates, and flows over the vertical partition into the second compartment, where it is spread over the surface of peat beds with which the compartment is filled. An outlet for the liquid is provided at the bottom of the second chamber.—W. P. S.

Liquids; Process for sterilising — by means of ultra-violet rays. Soc. Le Ferment. Fr. Pat. 491,204, Mar. 25, 1909.

THE liquid is circulated through a closed vessel containing one or more mercury vapour lamps, the latter being so fixed that they are immersed in the liquid. Taps on the inlet and outlet pipes enable the velocity of the current of liquid to be controlled, and the outlet pipe may deliver the treated liquid into sterilised receptacles.—W. P. S.

PATENTS.

Sulphur; Process of treating finely-divided — for giving it the property of mixing readily with water. P. Ducancel and H. Gouthière et Cie. Fr. Pat. 401,067, July 6, 1908.

FINELY-DIVIDED commercial sulphur is incorporated with barium, strontium, or calcium saccharate, and thereby gains the property of mixing readily with water. The product may be employed for the treatment of vine-mildew.—F. SODX.

Disinfectant. H. Schneider, Wilmersdorf, Germany. U.S. Pat. 934,844, Sept. 21, 1909.

SEE Eng. Pat. 3789 of 1907; this J., 1907, 712.—T. F. B.

XIX.—PAPER, PASTEBOARD, &c.

PATENT.

Paper to be used as a substitute for india-rubber, leather, and the like. F. Poirier, Paris. Eng. Pat. 20,616, Sept. 30, 1908.

THE bark of the two varieties of Japanese paper mulberry called "kazokodzou" and "gampi" is scraped, beaten to fine particles, boiled in water, washed, dried, sifted, and boiled in "clear lye." It is then mixed with a glutinous mass composed of: glycerin, 10; rice-powder, 2; glue or size, 2; camphor oil, 1; water, 3; ochre, 1; and Chinese ink, 1 per cent. A paper is made from the paste thus obtained and is afterwards coated on both sides with the glutinous mixture mentioned above. The product can be used in many cases as a substitute for india-rubber, canvas, etc. It is impermeable to water.

—S. H. H.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENTIAL OILS, & EXTRACTS.

Cinchona alkaloids; Iodine derivatives of —. T. Kózniewski. Anz. Akad. Wiss. Krakau, 1909, 734—746. Chem. Zentr., 1909, 2, 989—990.

BY the action of a solution of iodine in carbon bisulphide on alcoholic solutions of cinchonine and quinidine, the author has prepared di-iodo-derivatives of the bases, analogous to those previously obtained from strychnine and brucine (see this J., 1909, 38). The cinchonine compound, $C_{19}H_{22}N_2O_{12}$, forms orange-yellow microscopic prisms melting with decomposition at 147° — 149° C. The quinidine compound, $C_{26}H_{34}N_2O_{12}$, melts at 157° — 159° C. with decomposition. These di-iodo-compounds are insoluble in petroleum spirit (ligroïne); almost insoluble in ether, benzene, and carbon bisulphide; somewhat more soluble in acetone, absolute alcohol, ethyl acetate, amyl alcohol, and chloroform. By the action of a solution of potassium hydroxide in methyl alcohol, the di-iodo-compounds lose the whole of their iodine, the alkaloids being regenerated. Di-iodocinchonine when heated with a large quantity of alcohol under a reflux condenser is dissolved, with decomposition. Di-iodoquinidine can be recrystallised from warm 90 per cent. alcohol, but on repeating the operation, the iodine content gradually falls unless a solution of iodine in carbon bisulphide be added. The hydrogen iodide and methyl iodide addition-compounds

of di-iodocinchonine and the methyl iodide and ethyl iodide compounds of di-iodoquinidine were also prepared. The author also succeeded in obtaining di-iodo-compounds from papaverine, golden-yellow needles, m. pt. 126—127° C.; berberine, small dark yellow needles; and thebaine, red prisms; further an iodine derivative of narcaine. No corresponding derivatives of morphine, codeine, aconitine, codeine, and veratrine could be prepared, and it is concluded that only those alkaloids the molecules of which contain a quinoline or isoquinoline nucleus are capable of yielding additive di-iodo-compounds.

—A. S.

Strychnine, brucine, and other alkaloids: Bromination of — J. Buraczewski and M. Dziurzynski. *Anz. Akad. Wiss. Krakau*, 1909, 632—641. *Chem. Zentr.*, 1909, 2, 988—989.

ON adding a solution of bromine in carbon disulphide to a cold saturated solution of strychnine in alcohol, a yellow coloration is first produced, and later, a yellow precipitate. The latter, when dried at 80° C., has the composition of a dibromo-derivative of strychnine, $C_{21}H_{22}N_2O_2Br_2$, but is not identical with Beckurt's dibromostrychnine (Ber., 18, 1237). It decomposes on heating, without melting, and is insoluble in cold water, and nearly so in the common organic solvents; it is decolorised when boiled with ethyl or methyl alcohol. The alcoholic filtrate from the dibromo-derivative, when treated with alkalis, yields a precipitate of a monobromostrychnine, not identical with the earlier known α -monobromostrychnine. The new monobromoderivative forms white, silky, fibrous crystals, melting at 250° C.; it is easily soluble in alcohol, and in acids, with formation of salts. On further bromination it yields products having the composition of tri- and tetra-bromoderivatives of strychnine. When a solution of bromine is added to an alcoholic solution of brucine, there are formed first a white gelatinous precipitate, which gradually dissolves on further addition of bromine, and then a dark yellow precipitate; with a large excess of bromine, this yellow precipitate is not produced, but the solution becomes dark reddish-violet after standing for a few days. The gelatinous precipitate is a monobromobrucine, $C_{23}H_{25}BrN_2O_4$, not identical with that isolated by Laurent. When washed with alcohol and ether, it yields a white pulverulent substance almost insoluble in cold water and the common organic solvents. It dissolves in mineral acids with production of a cherry-red coloration. The yellow precipitate consists of a brucine tribromide, $C_{23}H_{25}N_2O_4Br_3$; when boiled with water it dissolves, forming a red solution, just as Beckurt's brucine tribromide does, but unlike the latter, it is not hygroscopic.

—A. S.

Brucine: A base isomeric with — G. Mosser. *Ges. Deutscher Naturforscher u. Aerzte*, Sept., 1909, Z. Allgem. österr. Apoth.-Ver., 1909, 47, 417—419.

WHEN cyanogen bromide is allowed to act upon brucine dissolved in chloroform, two substances are formed, one of which is soluble, the other insoluble in chloroform. The soluble substance is the hydrobromide of a base isomeric with brucine, and described as *allobrucine*, $C_{23}H_{26}N_2O_4$. The free base crystallises from alcohol and water in long crystals, containing 5 molecules of water. Allobrucine containing water of crystallisation melts at 69.5° C., then becomes solid on further heating, and again melts at 182° C. The anhydrous form becomes transparent at 126—128° C., and melts at 182° C. When boiled with water or dilute alcohol, allobrucine is more or less converted into brucine. It has $[\alpha]_D^{20} = -112.2^\circ$ to -113° in chloroform. The methiodide, $C_{23}H_{26}N_2O_4I$, melts at 265° C., and contains 11 molecules of water of crystallisation. The peroxide, $C_{23}H_{26}N_2O_6 \cdot 5H_2O$, m. pt. 182° C., is formed when allobrucine is warmed with hydrogen peroxide solution. If the peroxide is heated to 110° C., it loses oxygen and passes into allobrucine oxide, $C_{23}H_{26}N_2O_5 \cdot H_2O$, which also melts at 182° C. Brucine peroxide can be made in the same way. It crystallises with 4 molecules of water, of which two are lost on drying the substance in a vacuum. The air-dried crystals melt at 124° C., whilst the substance after drying in a vacuum melts at 191°—196° C. Sodium

ethoxide converts allobrucine into allobrucinic acid, $C_{23}H_{28}N_2O_5 \cdot 7H_2O$, which melts at 165°—166° C. This substance is not decomposed by boiling water, but is easily converted into brucine by the action of dilute acids.

—F. SUDS.

Pseudocodeine. L. Knorr, H. Butler, and H. Hörlein. *Annalen*, 1909, 368, 305—323.

PSEUDOCODEINE (this J., 1907, 66) was made by boiling α -chlorocodeide with water and acetic acid; it melts at 180°—181° C. When phosphorus pentachloride acts upon pseudocodeine, a mixture of α -chlorocodeide and pseudo-chlorocodeide is produced. The latter is an oily substance, which gives a crystalline methiodide, melting at 185—186° C., and with $[\alpha]_D^{20} = -227.4^\circ$ to -229° at 15° C. When pseudocodeine is treated with phosphorus tribromide, the same bromocodeide is produced as that obtained from codeine. ϵ -Methylmorphinethine (*loc. cit.*) crystallises from ether, and melts at 129°—130° C. It has $[\alpha]_D^{20} = -120.1^\circ$ at 15° C. in alcohol. This substance is not affected by boiling with potassium hydroxide solution. When the methiodide of ϵ -methylmorphinethine is heated under pressure with alcohol and potassium hydroxide, morphenol and trimethylamine are produced. If ϵ -methylmorphinethine is heated to 180° C. with acetic anhydride, methylacetyl-morphol and ethanoldimethylamine are produced.—F. SUDS.

Odoriferous plants and essential oils. Roure-Bertrand fils. *Chem. Zentr.*, 1909, 2, 1055—1056.

THE analytical characters of three samples of essential oil of *Schinus molle* L. of different origin are shown in the following table. Nos. 1 and 2 were from Algiers, the former being distilled from the twigs, leaves, woody parts, and fruits of the plant, and the latter from the leaves alone; No. 3 was prepared in the same way as No. 1 from plants cultivated in Grasse.

	No. 1.	No. 2.	No. 3.
Sp. gr. at 15° C.	0.8634	0.8658	0.8696
Rotatory power at 15° C.	+59° 54'	+65° 20'	+46° 13'
Solubility in 90 per cent. alcohol	1:5	1:3	turbid at 1:10
Acid value	0	0.7	2.1
Saponification value.....	5.5	4.1	10.3
Percentage of esters, as lunalyt acetate	1.9	1.2	2.8
Saponification value of acetylated oil	29.4	40.4	43.4

The oils contained pinene and phellandrene, and probably also sesquiterpenes. The Grasse oil was richest in pinene. A sample of Grasse peppermint oil examined yielded no crystals even at -17° C. From a specimen of 1907 oil having the acid value, 0.2, and containing 10.6 per cent. of combined menthol and 6.4 per cent. of menthone, there were isolated: isovaleric aldehyde, isoamyl alcohol, *l*-pinene, a hydrocarbon melting at 165°—167° C., *i*-cineol, secondary *l*-menthol, and *l*-menthone (b. pt. 208° C.; $[\alpha]_D^{20} = -26.50^\circ$).—A. S.

Pinene: Conversion of — into *sobrerol*. G. G. Henderson and W. J. S. Eastburn. *Chem. Soc. Trans.* 1909, 95, 1465—1466.

BY oxidation with aqueous mercuric acetate in the cold, Henderson and Agnew (this J., 1909, 258) obtained optically inactive *sobrerol* from a pinene which was itself almost optically inactive. Analogous experiments with two specimens of *d*-pinene from Burmese and American oil of turpentine respectively, and one of *l*-pinene from French oil of turpentine showed that in each case the *sobrerol* produced was inactive.

It is suggested that the production of *sobrerol* by oxidation with mercuric acetate may be used as a test for pinene. Tests in this manner with fractions of Russian and Swedish oil of turpentine indicated that there is a small proportion of pinene in the former, but none, or only traces, in the latter.—A. S.

Camphor; *Rapidity of volatilisation of* —. C. H. La Wall. Amer. Drugg., 1909, 55, 107—108.

LUMP camphor, exposed in a large, dust-free cupboard, lost 1.56 per cent. of its weight in 24 hours; 8.74 per cent. in 4 days; 23.46 per cent. in 14 days; 43.34 per cent. in 28 days; and 61.95 per cent. in 45 days. Powdered camphor, similarly exposed, lost 8.8 per cent. in 24 hours; 33.3 per cent. in 4 days; 83.7 per cent. in 14 days; and 99.9 per cent. in 20 days. Liniment of camphor (camphorated oil) containing the official percentage, 20 per cent. of camphor, after being exposed in an uncorked bottle at an almost constant temperature of 40° C. for 14 days, contained 19.75 per cent. of camphor; and after one month, 19.21 per cent. Another portion similarly exposed at ordinary room temperature lost less than 0.25 per cent. of camphor in a month. Spirit of camphor, when exposed in uncorked bottles gains in its camphor content, the volatilisation of the alcohol being more rapid than that of the camphor. A sample of this spirit containing 10 grms. of camphor in 100 c.c., gave 11.47 grms. in that volume after 14 days exposure, and 12.04 grms. after one month.—J. O. B.

α-Eucaine [methyl ester of benzoylmethyltetramethyl-γ-hydroxypiperidinecarboxylic acid] and *β-eucaine* [benzoylmethylacetonealkamine hydrochloride]; *Distinctive reaction for* —. *Distinction between cocaine and its substitutes*. U. Saporetti. Boll. Chim. Farm., 1909, 48, 479—482. Chem. Zentr., 1909, 2, 1015.

CONTRARY to the statement of Caudussio (this J., 1908, 1130), the author finds that with a solution of iodine in potassium iodide, *α*- and *β*-eucaine yield immediately a chestnut-brown or a dark rusty brown precipitate. With bromine water, *β*-eucaine gives a yellow precipitate which is partially dissolved on warming, and is converted into a white precipitate on boiling; *α*-eucaine gives a yellow precipitate which dissolves completely on heating; cocaine, novocaine (*p*-amino benzoyldiethylaminoethanol hydrochloride), stovaine (hydrochloride of the benzoyl ether of dimethylaminopentanol), alypine (benzoyl tetramethyldiaminoethyl dimethylethanol hydrochloride), and nirvanine (diethyl glycol-*p*-amino-*o*-hydroxybenzoic acid methyl ester hydrochloride) behave in the same way as *α*-eucaine. With a solution of potassium iodide (1:10), cocaine, *α*-eucaine, nirvanine, and stovaine yield a white precipitate, which partially dissolves on boiling; *β*-eucaine, novocaine, and alypine do not give a precipitate. With mercuric chloride solution, *α*-eucaine, novocaine, nirvanine, and alypine give a precipitate which dissolves on heating; *β*-eucaine, cocaine, and stovaine give no reaction. With sodium hydroxide solution, *α*-eucaine, stovaine, alypine, and nirvanine give a white precipitate, insoluble in excess of the reagent, even on boiling. Potassium permanganate solution is not decolorised by *β*-eucaine; with the other substances mentioned, violet-blue precipitates are first produced, which later become brown, whilst the solution is gradually decolorised.—A. S.

Astrolin [antipyrine-methylethylglycollate]. E. Winzheimer. Pharm. Zeit., 1909, 54, 660—661.

ASTROLIN is the commercial name of antipyrine methylethylglycollate, $C_8H_{10}O_3 \cdot C_7H_7O_2N_2$, m.pt. 64°—65.5° C. It is a colourless, non-hygroscopic powder, with a slight odour and a pleasant acid taste; soluble in 0.6 part of water at 20° C., in 0.5 part of absolute alcohol, in about 75 parts of ether, and sparingly soluble in light petroleum spirit. Its aqueous solution should be clear and give an acid reaction with litmus, but almost neutral with Congo red. It gives a blood-red colour with ferric chloride; with sodium nitrite a green colour is produced without the addition of acetic acid, and the mixture soon deposits green crystals. One gm. of astrolin should require 6.53 c.c. of *N*/2 sodium hydroxide solution before giving a red colour with phenolphthalein, this being equivalent to 0.3856 gm. of methylethylglycollic acid. The liquid after this titration should yield 0.61 to 0.62 gm. of antipyrine when extracted with 3 successive 15 c.c. of chloroform. The aqueous solution left after extracting the antipyrine with chloroform should give a yellow

colour with ferric chloride. On liberating the methylethylglycollic acid by means of an excess of sulphuric acid, adding sodium sulphate, and extracting with ether, the residue obtained on evaporating the ether should consist of colourless crystals, melting at 71—72° C. after drying over sulphuric acid. The aqueous solution of these gives a bulky colourless crystalline precipitate with zinc acetate.—J. O. B.

Condensation products of aldehydes with amines; *Electrochemical reduction of* —. K. Brand. Ber., 1909, 42, 3460—3462.

By the electrochemical reduction of benzylidenedianiline and its analogues in moderately alkaline solution, with a lead cathode, good yields of the corresponding secondary amines can be obtained. In the author's experiments, the cell used consisted of a glass beaker in which was an earthenware jar, which formed the anode chamber and was surrounded by a cylindrical perforated cathode of sheet lead; the anode consisted of a piece of sheet lead. A saturated solution of sodium carbonate was placed in the earthenware jar, whilst in the outer compartment was placed a hot solution of 18 grms. of benzylidenedianiline and 15 grms. of sodium acetate in 200 c.c. of alcohol and 30 c.c. of water. Electrolysis was effected at 80° C. with an E.M.F. of 6—8 volts, the current-density being 1.5—2 amperes per 100 sq. cm. From the reaction-product, the alcohol was distilled off, the residual oil boiled with 10 per cent. hydrochloric acid, the acid solution filtered from insoluble resinous matter, and benzyldianiline recovered from the filtrate either by crystallisation as the hydrochloride or by adding caustic soda and distilling. The hydrochloride melts at 214°—216° C.; the free base melts at 37°—38° C. and boils at 306°—307° C. at 759 mm. *p*-Methoxybenzyldianiline was prepared in a similar manner from *p*-methoxybenzylidenedianiline.—A. S.

Aniline derivatives; *Toxicity of certain* —. Hildebrandt. Int. Med. Congr., Aug.-Sept., 1909, Chem.-Zeit., 1909, 33, 997.

THE toxicity of the toluidines varies with the position of the methyl group. Thus *o*-toluidine causes the separation in the urine of the colouring matter of the blood, whilst dimethyl-*o*-toluidine, which is the most poisonous of all, not only has an action upon the blood, but also causes fatty degeneration of the inner organs, such as the liver. The introduction of one atom of bromine into the *p*-position does not affect the toxicity, but if two atoms of bromine are introduced into the complex, the toxic action of the compound upon the blood is entirely prevented, whilst its effect in producing fatty degeneration is reduced, though not altogether checked. Dibromodimethyl-*o*-toluidine is more poisonous than tribromoaniline. It thus appears that a most important factor in the toxicity of aniline derivatives is the presence of the methyl group in the *o*-position.—C. A. M.

Hydrazine hydrate; *Action of calcium oxide on* —. A. Staehler. Ber., 1909, 42, 3018—3019.

THE method usually employed for the preparation of anhydrous hydrazine consists in distilling hydrazine hydrate with barium oxide. On attempting to use calcium oxide in place of barium oxide, it was found that a vigorous reaction takes place on adding the calcium oxide to hydrazine hydrate. On subsequently distilling, pure anhydrous hydrazine comes over at first, and then, later, hydrazine contaminated by ammonia.—A. S.

Nitromethane; *Preparation of* —. W. Steinkopf and G. Kirchhoff. Ber., 1909, 42, 3438—3440.

THE method used now by the authors in place of the one previously described (this J., 1909, 259) consists in using as the reaction-mixture, 500 grms. of chloroacetic acid dissolved in 1 litre of water, 280—300 grms. of calcined sodium carbonate, and 300 grms. of sodium nitrite dissolved in 500 grms. of water. Only a portion of the reaction-mixture is heated at first, and when the nitromethane begins to distil over, the remainder is added drop by drop whilst distillation is proceeding. By making

the process continuous, 2 kilos. or more of chloroacetic acid can easily be converted into nitromethane in one day. For this purpose the distillation flask carries a tap-funnel for holding the reaction-mixture and is provided with a tube reaching nearly to the bottom, which can be connected with a water-pump in order to remove the spent reaction mixture as desired.—A. S.

Solubility of sparingly soluble acids; Influence of various sodium salts on the —, J. C. Philip and F. B. Garner. Chem. Soc. Trans., 1909, 95, 1466—1473.

IN a previous paper (see this J., 1905, 818) it was shown that the solubility of a sparingly soluble acid is markedly increased in presence of the sodium salt of a weak acid, the influence of the salt being greater, the weaker the acid from which it was derived. Further experiments have now been made with benzoic acid (0.0277), salicylic acid (0.0161), *m*-nitrobenzoic acid (0.0205), *o*-chlorobenzoic acid (0.0136), 3,5-dinitrobenzoic acid (0.0062), and 2,4-dinitrophenol (0.0027), in presence of the sodium salts of acetic, formic, monochloroacetic, and succinic acids, and potassium formate. The figures given in parentheses represent the concentrations of the saturated aqueous solutions of the acids at 25° C. in grm.-mols. per litre. The results obtained confirm the statement made above, and show also that if, of two sparingly soluble acids, the weaker is also the more soluble, then the solubility of the stronger acid is increased to a greater degree than that of the weaker one by the presence of a sodium salt. If the difference in solubility of two such acids in water be not too great, then the curves representing the solubility in presence of different quantities of a sodium salt will intersect. For example, in water benzoic acid is more soluble than salicylic acid, but in sodium formate solutions of a greater concentration than 0.06 *N*, salicylic acid is more soluble than benzoic acid.—A. S.

Anhydrides of aromatic sulphonic acids. H. Meyer. Ges. Deutscher Naturforscher u. Aerzte, Sept., 1909. Chem.-Zeit., 1909, 33, 1936—1937.

THE production of aromatic acyl chlorides by the action of phosphorus pentachloride on the alkali salts of sulphonic acids has in some cases failed. The author has found that in all such cases, where the alkali salts are attacked either not at all or only with difficulty, the free sulphonic acids readily interact with phosphorus pentachloride. A similar condition of things has been observed with respect to the interaction of aromatic sulphonic acids and thionyl chloride. In general, a sulphonic acid that reacts readily with thionyl chloride yields the corresponding acyl chloride, whilst an alkali sulphonate yields the anhydride of the sulphonic acid, more or less contaminated by the acyl chloride. Sulphonic acids, which in the form of their alkali salts, react only with difficulty with thionyl chloride, yield when used in the free state, the corresponding anhydrides, usually immediately and in a pure condition. The anhydrides can be converted into the acyl chlorides by further treatment with phosphorus pentachloride or thionyl chloride. The anhydrides of aromatic sulphonic acids are colourless and odourless, well crystallised compounds, of considerable stability against water and weak alkalis, and soluble with difficulty in organic solvents. Incidentally the author points out that the efficacy of aluminium chloride as a condensing agent is increased by addition of some ferric chloride.—A. S.

Mercurous sulphate for standard cells [and crystallised cadomil]. Fox. See XI.A.

Determining arsenic in organic compounds. Little and others. See XXIII. Org. Quant.

PATENTS.

Aminoacyldipyrrocatechins; Manufacture of — and of intermediate products for use therein. P. A. Newton, London. From Farbenfabr. vorm. F. Bayer und Co., Elberfeld, Germany. Eng. Pat. 23,143, Oct. 30, 1908.

THE *N*-phthaliminoacyldipyrrocatecholdialkyl ethers, described in Ger. Pat. 209,962 of 1908 (this J., 1909, 675), are

converted by saponification into the corresponding aminoacyldipyrrocatechols. The preparation of α - and β -*N*-aminopropionylcatechols is described.—T. F. B.

Tubercle or murrain bacilli; Process for obtaining active preparations from —. Kalle und Co. Ger. Pat. 213,393, July 10, 1908.

TUBERCLE or murrain bacilli are cultivated for about six weeks on bouillon, then separated from the culture liquid by filtration, dried, and triturated with a few drops of glycerin and a few c.c. of a solution of sodium chloride and phenol to a very fine emulsion. The latter is mixed with the filtered culture liquid, and allowed to stand for some time, with frequent agitation. After again filtering, the solution is said to contain nearly the whole of the active constituents of the bacilli and their transformation products.—A. S.

*Alkyl derivatives of substituted *p*-aminophenols; Process for preparing —.* Chem. Fabr. auf Actien, vorm. E. Schering. Ger. Pat. 213,592, Nov. 30, 1907. Addition to Ger. Pat. 211,869, Oct. 12, 1906. (See Fr. Pat. 382,367 of 1907; this J., 1908, 246).

SUBSTITUTION products of *p*-aminophenol (substituted in the benzene nucleus) are condensed with aromatic aldehydes, and the products are reduced by means of zinc and alkali. *p*-Benzylamino-*m*-chlorophenol and *p*-benzylamino-*m*-cresol are described. The products are suitable for photographic and other purposes.—T. F. B.

Convallaria majalis; Process for obtaining from — a stable preparation containing the therapeutically active constituents of the drug in their original proportions, and free from inactive and injurious substances. Knoll und Co. Ger. Pat. 213,630, Aug. 25, 1908.

THE alcoholic extract of *Convallaria majalis* (lily of the valley), if desired, after concentration *in vacuo*, is treated with ether so long as a precipitate is produced, then filtered, concentrated *in vacuo*, and after addition of lactose or other suitable substance, dried so as to obtain a yellow powder, which dissolves easily in dilute alkalis, but is not completely soluble in water and dilute acids.—A. S.

Silver compounds containing organically combined silver; Process for preparing stable, soluble —. A. Busch. Ger. Pat. 213,712, March 3, 1908. Addition to Ger. Pat. 193,740, Dec. 13, 1906.

HEXAMETHYLENETETRAMINE-SILVER nitrate or carbonate is dissolved in a solution of a peptone or of a mixture of an albumose and a peptone, and the double silver compound precipitated as in the original patent (this J., 1908, 645. See also Ger. Pat. 209,345; this J., 1909, 626).—T. F. B.

Indole; Process for preparing —. R. A. Weerman. Ger. Pat. 213,713, July 18, 1908.

IF the amide of *o*-nitrocinnamic acid is heated with an alkali hypochlorite and an alcohol (preferably methyl alcohol), it is converted into the alkyl ester of *o*-nitrostyrylaminoformic acid, $\text{NO}_2\text{C}_6\text{H}_4\text{CH}:\text{CH}.\text{NH}.\text{COOR}$. This is reduced to the corresponding amino-compound, preferably by means of iron powder and dilute acetic acid, and the reduction product is treated with alkali, when ammonia and the alcohol are eliminated, and indole is formed.—T. F. B.

Salicylosalicylic acid; Process for preparing a crystallised —. C. F. Boehringer und Soehne. Ger. Pat. 214,044, April 9, 1908. Addition to Ger. Pat. 211,403, May 24, 1907.

THE crystalline salicylosalicylic acid described in the principal patent (Eng. Pat. 11,457 of 1908; this J., 1909, 382) is readily obtained by the action of salicylic acid on the products obtained by treating salicylic acid with acid condensing agents, such as phosphorus trichloride, pentoxide, or pentachloride, or thionyl chloride.—T. F. B.

Albumose; Process for the preparation of —. P. Runge.
Ger. Pat. 214,209, Sept. 26, 1908.

CASEIN is hydrolysed in the usual manner with a solution of an alkali, an alkaline-earth, or an alkali sulphide, and the alkaline albumose solution is treated with one of the higher fatty acids, preferably palmitic, stearic, oleic, or linolic acid. The resulting mixture of albumose and soap is dried, and the soap removed by extraction with alcohol or other suitable solvent.—A. S.

Ethoxyphenylamidomethane sulphonate. R. Lepetit, Assignor to Lepetit, Dollfus, and Gansser, Milan, Italy.
U.S. Pat. 934,554, Sept. 21, 1909.

SEE Eng. Pat. 21,389 of 1908; this J., 1909, 490.—T. F. B.

Chlor-acetic acid; Process of obtaining —. G. Imbert, Nuremberg, Germany. U.S. Pat. 935,606, Sept. 28, 1909.

SEE Eng. Pat. 5013 of 1907; this J., 1907, 637.—T. F. B.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

PATENTS.

Screens for use in colour photography; Manufacture of —. L. Dufay, Chantilly, France. Eng. Pat. 18,744, Sept. 7, 1908. Addition to Eng. Pat. 11,698 of 1908, dated June 4, 1907. Under Int. Conv., May 26, 1908.

SCREENS similar to those described in the principal patent (this J., 1909, 383) are obtained by mechanically applying a greasy resist to a fraction (two-thirds for a three-colour screen) of the surface of a gelatin film, dyeing the part uncovered, and covering the whole with a varnish, the resinous base of which is insoluble in a solvent of the greasy resist, and the solvent of which does not dissolve the resist. The greasy material is now removed, together with the varnish which covers it, thus leaving one-third of the surface coloured and coated with varnish. The process is repeated for the second coloration (or all but the last, if there be more than three), and the free spaces are coloured with the last colour, when the varnish is removed. When these screens are used for making coloured prints, they may be reduced in intensity, if necessary, by removing a portion of the thickness of the layer, either by mechanical or by chemical means.—T. F. B.

Photographic developers. W. F. C. Kelly and J. A. Bentham, London. U.S. Pats. 935,115 and 935,156, Sept. 28, 1909.

SEE Eng. Pat. 3164 of 1905; this J., 1906, 560.—T. F. B.

Aralkyl derivatives of substituted p-aminophenols. Ger. Pat. 213,592. See XX.

XXII.—EXPLOSIVES, MATCHES, &c.

Silver cyanamide. Ellis. See XV.

PATENTS.

Explosive. O. F. von Schroetter, Kruppamühle, Germany. U.S. Pat. 934,020, Sept. 14, 1909.

SEE Eng. Pat. 8156 of 1907; this J., 1907, 893.—T. F. B.

Explosives; Device for detecting decomposition of —. E. Bouchaud-Praceiq, Paris. U.S. Pat. 934,509, Sept. 21, 1909.

SEE Addition of May 4, 1908, to Fr. Pat. 388,142 of 1907; this J., 1909, 1007.—T. F. B.

Recovery of alcohol and ether lost in the air during the manufacture of powder. Fr. Pat. 401,182. See I.

Recovery of solvents of nitrocellulose. Fr. Pat. 401,262. See V.

XXIII.—ANALYTICAL CHEMISTRY.

APPARATUS.

PATENT.

Gas-burettes for gas analysis; Device for filling and emptying —. C. Hohmann, Ger. Pat. 212,338, July 29, 1907.

A GAS-ANALYSIS apparatus in which, by means of a connected series of siphons and overflows, with mercury seals, the use of cocks and of movable levelling vessels is dispensed with.—A. S.

INORGANIC—QUANTITATIVE.

Phosphoric acid; Determination of — in acid solution by means of alkaline molybdate solution and glue. A. Grete, Ber., 1909, 42, 3106—3115.

THE volumetric method described by the author in 1888 (this J., 1888, 771) has been thoroughly tested in practice, over 100,000 analyses having been performed with it; and since 20 determinations can be carried through in one hour, with results equal in accuracy to those obtained by the gravimetric process, a description of the modified manner in which it is performed is now given. Instead of the nitric acid solution of molybdic acid, a solution rendered faintly ammoniacal is used; this is quite stable, and does not attack rubber tubing. The solutions used are prepared as follows:—(No. 1). 500—600 c.c. of glue solution (see under No. 2) and 1 litre of nitric acid are mixed, with constant agitation with a concentrated solution of 400 grms. of molybdic acid in ammonia solution till the precipitate produced no longer re-dissolves; after standing for one day, with frequent agitation, the solution is filtered, rendered faintly ammoniacal, and standardised against a solution of monopotassium phosphate so that 1 c.c. is equivalent to 0.0025 gm. of phosphoric anhydride. (No. 2). 1 kilo. of fish glue is dissolved in water to which 250 c.c. of nitric acid have been added, and boiled for $\frac{1}{2}$ hour; after cooling, the solution is made strongly ammoniacal, any phosphoric acid present precipitated with magnesia mixture, and after addition of about 50 c.c. of ammonium carbonate solution, the whole is diluted to 10 litres; when required for use, the necessary quantity of the solution is filtered and acidulated with nitric acid. (No. 3). 10 kilos. of ammonium nitrate and 8.5 litres of nitric acid are dissolved in about 25 litres of water, the solution is made up to 50 litres, and standardised so that 10 c.c. are equivalent to 64.8 c.c. of $N/4$ baryta. The solution of the phosphate to be titrated must be as free as possible from hydrochloric acid and from organic matter. It is first neutralised with ammonia in presence of methyl orange and then rendered faintly acid with nitric acid. Solutions containing less than about 4 per cent. of phosphoric anhydride should be mixed with 25 c.c. of a phosphoric acid solution of known concentration before carrying out the determination. A measured quantity of the faintly acid phosphate solution (25 c.c., containing 0.5 gm. of substance) is treated with 100 c.c. of the acid ammonium nitrate solution (No. 3), heated to boiling, and the molybdic acid solution (No. 1) run in slowly from a burette until a precipitate is produced, which on boiling the solution and shaking, rapidly settles. The titration, boiling and allowing to settle are continued until only a faint reaction is observed. Then 5—6 c.c. of the glue solution (No. 2) are added, the mixture boiled and allowed to settle, and the titration continued as before, only 3 drops of the molybdic acid solution being introduced each time. When after repeatedly boiling and allowing to settle in this way, the 3 drops of molybdic acid solution produce no precipitate, the volume consumed is read off, 2.6 c.c. are deducted (0.1 c.c. for the final 3 drops and 2.5 c.c. for the 100 c.c. of acid ammonium nitrate solution used), and the remainder divided by 2 gives the percentage of phosphoric anhydride in 0.5 gm. of the original substance.—A. S.

Diazotisation of weakly basic, sparingly soluble, primary amines, and some reactions connected therewith. Witt. See IV.

Examination of plaster of Paris. Frey. See IX.

ORGANIC—QUANTITATIVE.

Arsenic in organic compounds; Determination of —. H. F. V. Little, E. Cahen, and G. T. Morgan. Chem. Soc. Trans., 1909, 95, 1477—1482.

THE process found most satisfactory by the authors is a combination of Pringsheim's method of oxidation with sodium peroxide (this J., 1901, 504) and Gooch and Browning's volumetric method (Amer. J. Science, 1890, [iii.], 11, 66). 0.2—0.3 gm. of the finely-powdered substance is mixed in a nickel crucible with 10—15 grms. of sodium carbonate and sodium peroxide in equal proportions, a portion of these reagents being spread over the mixture. After heating gently for about 15 mins., the fusion is completed by heating to dull redness for 5 mins. The contents of the crucible are extracted with water and raised into a 450 c.c. conical flask, treated with 25—31 c.c. of sulphuric acid (1:1), and the volume reduced to 100 c.c. by boiling. One gm. of potassium iodide is now added and the liquid further concentrated to 40 c.c. After removing the last traces of iodine by means of a few drops of dilute sulphurous acid, the green solution is diluted with hot water and saturated with hydrogen sulphide. The arsenious sulphide is collected, washed, dissolved in 20 c.c. of N/2 sodium hydroxide and treated with 30 c.c. of hydrogen peroxide (20 vols.), the excess of the latter being destroyed by heating. A few drops of phenolphthalein are now added, followed by 11 c.c. of sulphuric acid (1:1) and 1 gm. of potassium iodide. The solution is concentrated to 40 c.c., decolorised with a few drops of dilute sulphurous acid, diluted with cold water, neutralised with 2N-sodium hydroxide, and slightly acidulated with sulphuric acid. An 11 per cent. solution of sodium phosphate (compare Washburn, J. Amer. Chem. Soc., 1908, 30, 31) is then added, and the arsenic solution titrated with iodine and starch in the usual way. The volume of sodium phosphate solution added should be about equal to that of N/10 iodine required in the titration. Compounds containing little or no oxygen require a proportionately larger quantity of sodium peroxide for oxidation. When the arsenic compound contains iodine, sodium iodate is formed on oxidation, and sufficient sulphurous acid must be added to the acidified extract to reduce this salt to iodide. The results are given of determinations by this method the arsenic in atoxyl (sodium *p*-aminophenylarsinate), hexamethyltriaminotriphenylarsine, dicamphorylarsinic acid, *p*-tolylarsinic acid, sodium tetraiodoacetylarsinate, triaminotriphenylarsine oxide, phenyltriaminotriphenylarsine, toluene-*p*-sulphonyl-*p*-aminophenylarsinic acid, *bis*-2-aminotolyl-5-arsinic acid, *bis*-*p*-acetylaminophenylarsinic acid, monosodium 4-hydroxy-2'-benzenazotoluene-5'-arsinate, and sodium 2-hydroxytolyl-5-arsinate.—A. S.

Phosphorus in organic substances; Determination of — by means of the bomb calorimeter. P. Lemoult. Comptes rend., 1909, 149, 511—513.

THE phosphorus in such substances as triethylphosphine, aniline phosphite, &c., may be determined by burning the substance in a bomb calorimeter provided that the substance be placed in a porcelain capsule coated on its interior with a layer of fused potassium nitrate; the nitrate ensures complete oxidation of the phosphorus and carbon. If plain capsules be used, a black deposit

containing phosphorus is usually found on the walls of the capsule. The phosphoric acid formed by the combustion dissolves in the water placed at the bottom of the bomb, and its quantity is then determined by precipitation as ammonium-magnesium phosphate.—W. P. S.

METALLOGRAPHIE. Ein ausführliches Lehr- und Handbuch der Konstitution und der physikalischen, chemischen und technischen Eigenschaften der Metalle und metallischen Legierungen. von Dr. W. GUERTLER. Erster Band: DIE KONSTITUTION. Heft I. Verlag von Gebrüder Bornträger, Berlin, S.W.11, Grossbeeren-Strasse 9. 1909. Price 4 M. 20 Pf.

LARGE 8vo volume, containing 80 pages of subject-matter, with 23 illustrations and 2 tables. The matter is classified as follows:—I. Introduction, with definition of metallography; the history of the latter. Alloys and their limits; etc. II. Constitution as dependent on temperature. III. Solid solutions and compounds. IV. Diagrams as to condition and composition.

DIE METHODEN ZUR HERSTELLUNG KOLLOIDER LÖSUNGEN ANORGANISCHER STOFFE. Ein Hand- und Hilfsbuch für die Chemie und Industrie der Kolloide. von Dr. THE SVEBERG. Theodor Steinkopff's Verlag. Dresden. 1909. Price M. 16; (bound), M. 18.

8vo volume, containing 499 pages of subject-matter, with 60 illustrations, numerous lesser tables, and three large tables. There are indexes both of names of authors, and of subjects. The subject-matter receives the following arrangement in groups and chapters:—I. METHODS OF CONDENSATION. (i.), Reduction; (ii.), Oxidation; (iii.), Hydrolysis, etc. II. METHODS OF DISPERSION. (i.), Mechanico-chemical, including (a), The washing-out methods, and (b), The peptising methods. III. METHODS OF ELECTRIC DISPERSION.

THE MANUFACTURE OF LEATHER. By HUGH GARNER BENNETT, M.Sc., Demonstrator and Assistant Lecturer in the Leather Industries Department of the University of Leeds. Constable and Constable, Ltd., London. 1908. Price 16s. net.

8vo volume, containing 408 pages of subject-matter, with 109 illustrations, numerous tables, and an alphabetical index of subjects. The subject-matter is classified according to the following scheme:—I. Historical, and introductory outline. II. The nature of skin. III. Fermentation. IV. Hides and skins. V. Water. VI. Soaking. VII. Unhairing. VIII. De-liming. IX. Tanning. X. Vegetable tanning materials. XI. Analysis of tanning materials. XII. Preparation of the tanning liquors. XIII. The principles of vegetable tanning. XIV. The tannage of sole leather. XV. The tannage of belting, harness, and upper leather, etc. XVI. Tannage of moroccos and light leathers. XVII. Tannage of chrome leather. XVIII. Alum and combination tannages. XIX. Fat, oil and aldehyde tannages. XX. The drying of leather. XXI. The finishing of sole leather. XXII. The currying and finishing of dressing leather. XXIII.

Leather dyeing. XXIV. The finishing of light leathers. XXV. Finishing of chrome leather. XXVI. Finishing of the alum- and combination-tanned leathers. XXVII. Finishing of fat- and oil-tanned leathers. XXVIII. Janned and enamelled leathers. XXIX. The dressing of wool rugs. XXX. The analysis of leather.

SYSTEMATIC QUALITATIVE ANALYSIS FOR STUDENTS OF INORGANIC CHEMISTRY. By R. M. CAVEN, D.Sc., Lecturer, etc., in Chemistry, University College, Nottingham. Blackie and Son, Limited, 50, Old Bailey, London, E.C. Also Glasgow, Dublin, and Bombay, 1909. Price 3s. 6d. net.

SMALL 8vo volume, containing 238 pages of subject-matter, one chart, and an enclosed analytical scheme covering two large sheets. The system adopted is as follows:—I. METHODS OF ANALYSIS. (a), Preliminary examination by dry reactions. (b), Systematic examination for basic and acidic radicles. II. REACTIONS OF THE METALLIC RADICLES. III. THE PROCESS OF ANALYSIS. (a), Preliminary examination by dry reactions. (b), Examination for acidic radicles which give volatile products with acids, and for ammonia. (c), Systematic examination for basic radicles in solution. (d), Examination for acidic radicles in solution.

PRACTICAL CHEMISTRY FOR PUBLIC SCHOOLS. By A. BERESFORD RYLEY, M.A. (Oxon.). J. and A. Churchill, 7, Great Marlborough Street, London. 1909. Price 4s. 6d. net.

8vo volume, containing 156 pages of subject-matter, interleaved with blank pages for notes, etc.; also a few illustrations. The arrangement of the text is as follows:—I. Introduction, with general physical and chemical reactions and tests, etc. II. Non-metallic elements. III. Acidimetry and alkalimetry. IV. Compounds of nitrogen. V. Equivalent and atomic weights, etc. VI. Proof of laws of constant and multiple proportions. VII. Sulphur, its allotropic forms, and its compounds. VIII. Phosphorus; allotropic forms, etc. Phosphine. Orthophosphoric acid. IX. Carbon; allotropic forms. Compounds. Coal gas. Flame. Causes modifying luminosity of flame. X. Halogen elements, and their compounds. XI. Simple qualitative analysis.

CHEMISTRY. Part II. Inorganic and Organic. (Catechism series.) New edition. Revised and enlarged. E. and S. Livingstone, 15, Teviot Place, Edinburgh. Price 1s. net.

SMALL 8vo volume, containing 73 pages of matter arranged in catechism form, followed by an alphabetical index.

Lo ZINCO. Di Prof. R. MUO-BOY. U. Hoepli, Milan, Italy. 1909. Price, Lire 3-50.

SMALL 8vo volume, containing 219 pages of subject-matter, with 10 illustrations and 4 inset plates. The subject-matter is classified as follows:—PART I. (1). Historical. (2). Properties of zinc. (3). Zinc ores. (4). Analysis of ores. (5). Determination of zinc in its ores. (6). Geological. PART II. (1). Metallurgy of zinc. (2). Calcination of calamine. (3). Roasting of blende. (4). Grinding of zinc ores. (5). Mechanical concentration of zinc ores. (6). Reduction of zinc ores. (7). Production of zinc by electrolysis. (8). Accessory operations to the metallurgy of zinc. (9). Thermo-electric treatment of zinc ores. (10). Alloys of zinc. (11). Analysis of zinc alloys. PART III. Zinc mining. PART IV. (1). Applications of zinc and its compounds. (2). Sheet zinc. PART V. (1). Economic conditions. (2). Production in recent years. Appendix. Manufacture of zinc white.

METALLOGRAFIA APPLICATA AI PRODOTTI SIDERURGICI. Di U. SAVOIA. U. Hoepli, Milan, Italy. 1909. Price, Lire 3-50.

SMALL 8vo volume containing 205 pages of subject-matter, with 94 illustrations, 85 of which are microphotographs. The text is divided as follows:—I. Historical. II. Preparation of specimens. III. The microscope. IV. Metallographic examination. V. Iron and its alloys. VI. Constituents of iron-carbon alloys. VII. Equilibrium-

diagram of iron-carbon alloys. VIII. Micro-structure of irons. IX. Micro-structure of steels. X. Carbon steels. XI. Ternary steels. XII. Quaternary steels. XIII. Cast iron. XIV. Malleable cast iron. XV. Study of a steel tempered only in one part. Bibliographies are appended to nearly all of the chapters.

CENSUS OF PRODUCTION (1907). Preliminary Tables, summarising the Results of the Returns received under the Census of Production Act, 1906. Part I. Wyman and Sons, Fetter Lane, E.C. [Cd. 4896.] Price 4d.

This return contains particulars relating to (1) Mines under the Coal Mines Regulation Acts (including coke and shale oil works in connection with mines); (2) Cotton factories; (3) Woollen and worsted factories; (4) Tin-plate factories; (5) Iron and steel factories (smelting, foundry, and rolling).

Patent List.

Where a Complete Specification accompanies an Application, an asterisk is affixed. The dates given are (i) in the case of Applications for Patents, the dates of Application, and (ii) in the case of Complete Specifications Accepted, those of the Official Journals in which acceptances of the Complete Specifications are advertised.

Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

I.—PLANT, APPARATUS, AND MACHINERY.

APPLICATIONS.

- 21,999. Ramsay and others. *See under X.*
- 22,163. Hodgkinson. Apparatus for evaporating brine or other solutions. [Comprised in No. 26,068 of 1908.] Sept. 29.
- 22,604. Gilmore. Drying apparatus. [U.S. Appl., Oct. 5, 1908.]* Oct. 4.
- 22,728. Ogle. Separating materials of different specific gravity. Oct. 5.
- 22,764. Armour. Electrical pyrometers. Oct. 6.
- 22,859. Barnes and others. Kilns. Oct. 7.
- 23,038. Töpfer. *See under XVIII.A.*

COMPLETE SPECIFICATIONS ACCEPTED.

- 20,921 (1908). Nobel and Bessonoff. Regenerating and utilising the latent heat of vaporisation of liquids. Oct. 13.
- 21,176 (1908). Bowden. Heat-insulation of pipes. Oct. 6.
- 22,738 (1908). Diederichs. *See under V.*

II.—FUEL, GAS, AND LIGHT.

APPLICATIONS.

- 22,219. Bedford and Williams. Catalytic synthesis of methane. Sept. 29.
- 22,290. Richards and Pringle. Apparatus for distilling coal and recovering the products. Sept. 30.
- 22,514. Wyld and Green. *See under VII.*
- 22,609. Sanders. Production of fuel. Oct. 4.
- 22,628. Schramm. *See under XIII.A.*
- 22,703. Bloxam (Sparlicht Ges.). Mantles for incandescent gas lamps.* Oct. 5.

COMPLETE SPECIFICATIONS ACCEPTED.

- 6966 (1908). Moore and Crombie. Plant for treating fuel and recovering and separating by-products. Oct. 13.
- 20,920 (1908). Burkholder. Purifying gases generated by dry distillation and obtaining by-products. Oct. 13.
- 174 (1909). Mayer and Fehlmann. Removing carbon bisulphide from gases, especially coal gas. Oct. 6.

- 3171 (1909). Lubeck and Payet. Catalytic material for automatic ignition of illuminating gas. Oct. 6.
6163 (1909). Morris. Manufacture of artificial fuel. Oct. 13.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

APPLICATIONS.

- 22,398. Newton (Bayer and Co.). Production of salts of *m*-aminobenzaldehyde; also the anhydro-compound of *o*-aminobenzaldehyde. Oct. 1.

COMPLETE SPECIFICATIONS ACCEPTED.

- 8768 (1909). Finlay. Manufacture of paraffin wax for candles and other purposes. Oct. 6.

IV. COLOURING MATTERS AND DYE STUFFS.

APPLICATIONS.

- 22,200. Kalle and Co. Manufacture of pure nitro-*o*-oxyazo dyestuffs. [Ger. Appl., Jan. 2, 1909.]* Sept. 29.
22,555. Newton (Bayer and Co.). Manufacture of new dyes. Oct. 4.
22,714. Johnson (Badische Anilin und Soda Fabrik). Manufacture of halogen derivatives of the indigo series. Oct. 5.

COMPLETE SPECIFICATIONS ACCEPTED.

- 24,600 (1908). Newton (Bayer and Co.). Manufacture of an azo dyestuff. Oct. 13.
1816 (1909). Johnson (Badische Anilin und Soda Fabrik). Manufacture of azo colouring matters. Oct. 13.
2373 (1909). Newton (Bayer and Co.). Manufacture of anthracene derivatives. Oct. 6.
6728 (1909). Bloxam (Act.-Ges. f. Anilinfabr.). Manufacture of yellow monoazo dyestuffs. Oct. 6.
10,187 (1909). Cassella and Co. Manufacture of red chromable dyestuffs. Oct. 6.
11,354 (1909). Act.-Ges. f. Anilinfabr. Manufacture of blue substantive dyestuffs. Oct. 13.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

APPLICATIONS.

- 21,952. Hahn. Skein-yarn mercersing machine.* Sept. 27.
22,111. Ketcheson. Treatment of fibrous or cellulose materials.* Sept. 28.
22,129. Blake and Blake. Treating fabrics for producing wall, roof, and similar coatings. Sept. 28.
22,343. Scott. Printing on cotton or other fabrics.* Oct. 1.
22,413. Ellis (Le Crinoid). Alkaline precipitating baths for cellulose threads. Oct. 1.
22,615. Mayo. Extraction of grease and similar matter from, and treating wool, skins, textiles, &c. Oct. 4.
22,986. Platt, and Times Coloured Spinning Co., Ltd. Apparatus for dyeing and similarly treating textile material.* Oct. 8.

COMPLETE SPECIFICATIONS ACCEPTED.

- 16,429 (1908). Gantt. Bleaching and otherwise treating fabrics with liquids. Oct. 13.
20,173 (1908). Raw and Orr. Treatment of ramie, china grass, and other fibrous substances. Oct. 6.
20,316 (1908). Draper. Manufacture of artificial fibres and the like from cellulose. Oct. 6.

- 24,191 (1908). Ellis (Le Crinoid Soc. Anon.). Manufacture of artificial hair or silky threads. Oct. 13.
21,621 (1908). Balmie and Ashton. Machines for dyeing, bleaching, and washing textile fabrics, &c. Oct. 13.
22,738 (1908). Diederichs. Apparatus for treating textile materials and for mixing liquids with chemicals, &c. Oct. 6.
5575 (1909). Maly. Dyeing woollen yarn on bobbins. Oct. 13.
5859 (1909). Vandatte and Lagye. Electrically removing grease and yolk from wool. Oct. 13.
14,760 (1909). Farjas and Jaboin. Radiferous fibres. Oct. 13.

VII.—ACIDS, ALKALIS, AND SALTS.

APPLICATIONS.

- 22,019. Justice (Cons. f. Elektrochem. Ind.). Production of hydrogen peroxide.* Sept. 27.
22,034. Jaubert. Preparation of oxygen. [Fr. Appl., Nov. 26, 1908.]* Sept. 27.
22,037. Pauling. Production of nitrous gases.* Sept. 27.
22,163. Hodgkinson. *See under I.*
22,316. Soc. l'Air Liquide. Separation of rare gases from the atmosphere. [Fr. Appl., Oct. 3, 1908.]* Sept. 30.
22,384. Wetter (Vogel). Antimony compounds.* Oct. 1.
22,514. Wyld and Green. Utilising sulphuretted oxide of gas-works in making sulphuric acid. Oct. 4.
22,585. Hewitt. *See under VIII.*
22,672. Messel. Manufacture of sulphur dioxide, sulphuric anhydride, and sulphuric acid. Oct. 5.
23,107. Jänecke. Continuous production of liquid air and its separation into its constituents.* Oct. 9.

COMPLETE SPECIFICATIONS ACCEPTED.

- 20,787 (1908). Lévy. *See under XI.*
21,479 (1908) and 7849 (1909). Clark (Dellwik-Fleischer Wassergas-Ges.). Production of hydrogen. Oct. 6.
2192 (1909). Schillot and Mauchaire. Apparatus for making dilute sulphuric acid. Oct. 13.
25,23 (1909). Johnson (Chem. Fabr. Griesheim-Elektron). Removing carbon monoxide from gases and replacing it by hydrogen. Oct. 6.
3188 (1909). Johnson (Chem. Fabr. Griesheim-Elektron). Preparation of pure hydrogen. Oct. 6.

VIII.—GLASS, POTTERY, AND ENAMELS.

APPLICATIONS.

- 22,041. Sievert. Manufacture of hollow glass bodies. [Ger. Appl., Jan. 23, 1909.]* Sept. 27.
22,585. Hewitt. Drying and burning or calcining slip, slurry, chalk, clay, limestone, &c. Oct. 4.
22,603. Hopper. Enamelling.* Oct. 4.
22,870. Goodwin. Frit kilns. Oct. 7.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

APPLICATIONS.

- 22,118. Cowper-Coles. Manufacture of bricks for furnaces. Sept. 28.
22,585. Hewitt. *See under VIII.*
22,839. Platten and Thompson. Manufacture of artificial stone, marble, granite, &c. Oct. 6.

COMPLETE SPECIFICATIONS ACCEPTED.

- 9147 (1909). Cie. Indus. des Alcools de l'Ardèche. Manufacture of absorbent products from sawdust or similar material. Oct. 13.
9381 (1909). Haddan (Meramec Portland Cement and Material Co.). Manufacture of waterproof Portland cement. Oct. 13.

X.—METALS AND METALLURGY.

APPLICATIONS.

- 21,999. Ramsay and others. Preventing corrosion of iron and steel water mains, tanks, &c. Sept. 27.
 22,047. Gebhard and Gebhard. Flux for soldering aluminium and its alloys. Sept. 28.
 22,088. Wheatley. Red-coloured alloy. Sept. 28.
 22,140. Robertson (Robertson). Extraction of tin and like metals from ores and slags. Sept. 29.
 22,201. Talbot. Manufacture of iron and steel. Sept. 29.
 22,394. Talbot. Converters or vessels for refining iron and steel. Oct. 1.
 22,426. Kelly. Manufacture of alloys. Oct. 1.
 22,445. South Staffordshire Mond Gas Co., and Parker. Oxidation of iron and steel surfaces. Oct. 2.
 22,472. London Electron Works Co., and Kardos. Detinning scrap tin or like materials. Oct. 2.
 22,743. Coslett Anti-Rust Synd., Ltd., and Coslett. Treating iron or steel to prevent oxidation or rusting. Oct. 5.
 22,812. Reynolds. Manufacture of steel. Oct. 6.
 22,902. Dichl and Faber. Winning iron low in sulphur. Oct. 7.
 22,928. Richardson. Manufacture of steel. Oct. 7.
 23,108. Ramen and Beskow. Roasting ores.* Oct. 9.

COMPLETE SPECIFICATIONS ACCEPTED.

- 13,366 (1908). Whitcombe and Cox. Apparatus for separating or grading metals, ores, &c., in wet recovery processes. Oct. 6.
 26,851 (1908). Schumacher. Process of briquetting ores. Oct. 6.
 28,260 (1908). Kostileff. Casting steel ingots. Oct. 6.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

APPLICATIONS.

- 22,374. Cowper-Coles. Electrodeposition of metals. Oct. 1.
 22,715. Johnson (Badische Anilin und Soda Fabrik). Electrodes and their use in producing stable electric arcs. Oct. 5.
 22,827. Podszus. Electric vapourising apparatus. [Ger. Appl., Oct. 7, 1908.]* Oct. 6.

COMPLETE SPECIFICATION ACCEPTED.

London Section.

Meeting held at Burlington House, on Monday, May 3rd, 1909.

DR. J. LEWKOWITSCH IN THE CHAIR.

A MACHINE FOR THE MECHANICAL TESTING OF INDIA-RUBBER.

BY CLAYTON BEADLE AND HENRY P. STEVENS, M.A., PH.D.

Some four or five years ago, in attempting to test the tensile strength of india-rubber goods, with a view to supplementing chemical analyses by physical tests, it was found that there was no machine to be had suitable for the purpose. Rubber samples are frequently so small and irregular in shape that it is difficult to cut strips of uniform size and thickness, and when they contain a small proportion of mineral matter they are liable to be crushed in the jaws and to tear at a point just inside one or other of the grips. Eventually it was found that tearing in the jaws could be overcome by cutting test pieces in the form of rings and stretching between smooth hooks. Stévant used rubber in the form of large rings for his physical experiments, but we believe that we were the first to use rings for tensile strength determinations.*

Recently Messrs. Schopper have brought out a testing machine for rubber on the swinging arm principle adopted in their other testing machines. They also use a fairly large ring-shaped test piece which they stretch over rotating pulleys so as to equalise the strain. This machine has already been described in detail†; its cost is high; and the published results‡ for a series of test rings cut from the same sheet of rubber show greater variations than similar tests made with our machine.

* Chem. News, July 26th, 1907, p. 41.

† See India Rubber Journal, May 17, 1909, pp. 565 and 566; also Lectures on India-rubber, 1908, p. 289.

‡ Beiträge zur Frage der mechanischen Prüfung von Weichgummi. Mitt. Kgl. Materialprüfungs amtes.

The testing machine designed by us consists of a smooth iron hook fixed to a stationary block, a second hook being fixed to a sliding block moving horizontally. To the latter a cord is attached passing over a pulley and carrying a light metal vessel. A pipe from a cistern with water at a constant level delivers a stream of water into the vessel, the supply being automatically cut off when the test ring breaks; the vessel and its contents are then weighed, giving the grams weight required to rupture the ring. The water is delivered into the vessel so that the tension increases at a uniform rate, say, 1000 grams per minute. After making the necessary allowance for any variation in the thickness of the ring from the 1 mm. standard, the result divided by 5 would give the tensile strength in terms of 1 sq. mm. sectional area. The elongation is measured by noting the position of a pointer or indicator attached to the sliding block which moves over the scale. By an automatic arrangement shown in the plan the hook attached to the movable block drops at the moment of rupture and releases the indicator, which remains at the point of total elongation. The plan shows details of the machine as constructed by Messrs. Baird and Tatlock, but if preferred it could be arranged vertically, the movable block sliding downwards, when the pulley would not be required. The figures given later were obtained with a machine of the horizontal type.

The test pieces are vulcanised in the form of sheets about 1 mm. thick. From these discs 10 mm. in diameter are punched, and the thickness of each disc is measured where necessary with an ordinary micrometer screw gauge with friction head set once for all so as to work with the same pressure. By a simple device a hole 5 mm. in diameter is punched in the middle of each disc, thus producing a ring which when stretched is equivalent to a strip with a sectional area of 5 sq. mm.

If desired the ring can be punched from the sheet in one operation. An appliance for this purpose is shown in the diagram.

If the article it is desired to test is not in the form of a thin sheet, as, for instance, a solid tyre, thin sections can be cut with a little practice from which the rings are punched. By cutting sections in different directions, as, for instance, parallel and at right angles to the base

About one-sixth size.

of the tyre, valuable information may be obtained on the structure of the rubber. This is one of the great advantages attaching to the use of small rings.

If the bucket is made to weigh 500 grams and the elongation is taken before the water is run in, we have the elongation produced by a strain equivalent to 100 grams per sq. mm. sectional area of sample, a useful figure. Further, measurements of the elongation can be made under any particular strain by running into or taking out from the bucket definite amounts of water. In place of the bucket a light aluminium pan can be used, and the test piece stretched under varying loads produced by adding or removing weights from the pan.

In this way it will be seen that the machine can be used for a variety of mechanical tests and for plotting hysteresis loops as well as for tensile strength determinations. This machine has been in constant use for three or four years in testing commercial samples as well as vulcanised plantation rubbers, and the number of tests made now amount to well over one thousand.

As illustrating the foregoing some results of tensile strength determinations are given.

(1) Solid rubber tyres (cab tyres).

Details of test on thin sheets about 1 mm. thick cut in cross section of tyre.

Rings 5 mm. internal diameter and 10 mm. external diameter giving a test piece equivalent to a sectional area of approximately 5 sq. mm.

Tensile strength of rings in grams weight for each ring.	Thickness of ring.	Tensile strength in grams per sq. mm.	Elongation at rupture, original length = 1.
3960	1.23	644	4.6
3670	1.25	588	4.2
3400	1.18	576	4.4
3060	1.01	595	4.6
3800	1.25	608	4.2
3470	1.05	661	4.6
3580	1.23	582	4.4
3450	1.08	638	4.4
3680	1.18	624	4.2
3280	1.12	586	4.4

(2) Unvulcanised plantation rubber.

Sheet 1 mm. thick :—

Tensile strength in grams per sq. mm.	Elongation at rupture, original length = 1.
204	2.2
226	2.3
230	2.4
208	2.2
206	2.3
228	2.4
210	2.8
250	2.4
Mean 216	2.3

As a rule, however, the thickness of each individual ring is not determined, but is measured up in batches of five. The average breaking strain per sq. mm. is then calculated for each batch of five, thus obtaining two results. If the mean of the two be taken, the average of the whole series is obtained, which at the same time provides a check on the accuracy of the results. If the mean of the two batches of five rings differs by more than 2 per cent. from the mean of either batch the results are rejected and a fresh series of tests made.

(3) Sheet of vulcanised plantation rubber.

The following table shows the details of such a series. The elongation produced by a load of 500 grams on the ring is also given, that is a load of 100 grams per 1 sq. mm. section. This figure is obtained by reading off the elongation after hanging on the water pan (which is adjusted to weigh 500 grams) before turning on the water.

Tensile strength in grams weight for each ring.	Mean thickness of each batch of 5 rings.	Mean tensile strength in grams per sq. mm.	Elongation at rupture, original length = 1.	Elongation with a strain of 100 grams per sq. mm.

Rubber Washer Punch.

Journal and Patent Literature.

PATENT SPECIFICATIONS may be obtained by post by remitting as follows :—

English.—8d. each, to the Comptroller of the Patent Office, W. Temple Franks, Esq., Southampton Buildings, Chancery Lane, London, W.C.

United States.—1s. each, to the Secretary of the Society.

French.—1 fr. 25 c. each, to Belin et Cie., 56, Rue des Francs Bourgeois, Paris (3e.).

German.—1 mark each (with full particulars) to Kaiserlich Patentamt, Berlin, Germany.

I.—PLANT, APPARATUS, AND MACHINERY.

PATENTS.

Liquid distributors for absorbing towers. W. Hommel and The Metals Extraction Corporation Ltd., London. Eng. Pat. 19,668, Sept. 18, 1908.

THE plates, C, C¹, C², which extend across the tower, A, are provided with saucer-shaped depressions, D, D¹, D².

Short vertical pipes, E, E¹, E², having their lower ends slit and splayed out into fingers, F, F¹, F², are passed through the depressions. The absorbing liquid enters the top of the tower through the pipe, G, is distributed over the plate, overflows through the vertical pipes, drips from the extremities of the fingers, and is finally discharged from the bottom of the tower through the pipe, H. The gas enters through the pipe, B, passes upwards through the

vertical pipes, and is thus brought into intimate contact either with the falling spray of liquid or with the film covering the pipes. If the whole of the gas is to be absorbed in the tower, or the residual portion taken off below the top plate, the vertical pipes are made rather longer and are covered with caps, K, serrated at their lower edges, L, which are sealed by the liquid contained in the caps so that the liquid but not the gas can pass through. The other plates of the tower, and in the case in which a portion of the gas is allowed to escape above the top plate, that plate also, are provided with shallow caps, K¹, K², having serrations, L¹, L², which allow liquid to enter and gas to escape.—W. H. C.

Filtering apparatus for use in connection with the washing of slimes and for similar purposes. J. F. Webb and P. Tarbutt, London. Eng. Pat. 21,474, Oct. 10, 1908.

THE filter consists of a flat box having one of its faces perforated and covered with filter-cloth. The box is attached to a machine by which it is lowered, with the perforated face downward, into a tank containing the slimes or other material to be filtered. The interior of the box is connected to a vacuum pump and the liquid is sucked through, leaving a cake of solid matter adhering to the outer surface of the perforated face of the box. When the cake is of sufficient thickness, the operator starts the machinery which raises the box, inverts it and tilts the inverted surface at an angle. Water is then sprayed on to the surface to wash the deposit, and the washings are sucked through into the box by the vacuum which is still maintained. When the deposit is sufficiently washed, both the water spray and the vacuum are shut off and the washed deposit is removed. The box is then lowered into the tank again by the machinery.—W. H. C.

Separating finely-divided materials. J. M. Seaver, Boston, Mass., U.S.A. Eng. Pat. 12,958, June 2, 1909.

FINE materials to be separated are fed into the chamber, K, through the openings, k, q, from the hopper, S, by the worm, R. They pass into the "cyclone," C, and the lighter particles are carried forward by the air current up the pipe, B, to the box, A¹. The finest particles pass with the air up the pipe, E, into the box, F, and thence into the bags, H, where they are arrested, while the air passes on. The coarser particles return by the shoots, A, and D, into the chamber, K. When the apparatus is first started, the bores of the bags, H, allow some dust to pass through

with the air. The doors, T, and M, are therefore kept closed at first and the air passes back from I, by the pipe, P, to K. As soon as the bags, H, are partially filled and they no longer allow the dust to pass, the doors, I, and M, are opened and the air enters at M and leaves at T. When the door, M, is closed, the flap, N, is opened by the air current from O.—W. H. C.

Separating substances of different specific gravities; Apparatus for —. J. M. Draper, Glasgow. Eng. Pat. 11,988, May 21, 1909.

THE apparatus is an improvement upon the jiggging machine described in Eng. Pats. 15,285 and 20,894 of 1906 (this J., 1907, 11, 12). In the machine illustrated (see Fig.), the box, 1, is reciprocated vertically in the tank, 6, by means of the driving shaft, 2; the pulsating water current so produced, causes the material on the perforated bottom, 4, to become stratified into layers of different specific gravity. To prevent the finest particles passing through the perforations at the point of entry and before stratification has taken place, that part of the box near the dam, 5, which first receives the material, is modified as shown, so that on the upward stroke the valve, 14, closes and the water does not pass through the perforations; on the downward stroke the water passing through the valve and the perforated plates, 7, and 12, forms a horizontal current impelling the material under the dam, 5, and a vertical current tending to stratify the material. Stratification proceeds as the material moves over the perforated bottom, 4; the lower layer passing under the gate, 15, and falling over the sill, 16, is removed by the scraper conveyor, 25a, and the upper layer rising over the sill, 31, is removed by a similar scraper conveyor, 25. The sills and gates are connected with external levers by which adjustment may be made.—J. W. H.

Transferring apparatus for fluids under high pressure. J. A. Hoff, Assignor to The Standard Carbonic Co., Cincinnati, Ohio. U.S. Pat. 927,798, July 13, 1909.

THE apparatus consists of a tube for holding one charge of compressed gas for such purposes as inflating motor-car tyres, and means for discharging and re-charging this tube. The tube carries a screwed plug having two small holes, one of which is central. Covering the central hole on the underside of the plug is a disc of thin metal which seals the tube when the plug is screwed down on its seating, the latter also having a central hole. The discharging apparatus is an arrangement for piercing the metal disc by a needle while the mouth of the tube is connected to the tyre or vessel to be charged. The re-charging device is a means for screwing the plug on its seating, after the gas has been allowed to enter the tube through the lateral hole in the plug, the central hole having had its thin metal disc renewed.—J. W. H.

Pulverisation, dispersion, and mixing of liquids; Process and apparatus for the —. Pages, Camus et Cie. and P. Bardy. First Addition, dated July 20, 1908, to Fr. Pat. 396,476, Jan. 27, 1908 (this J., 1909, 591).

VARIOUS forms of jets are described, all of which have the orifice from which the atomised liquid issues, partially closed by a disc or plug which can be regulated so as to give an annular opening of varying width. The object of blocking up the centre of the opening is to prevent the recombination of the different streams of atomised liquid.—W. H. C.

Hydraulic press for extracting the juices or water from pulps or other materials. X. M. Roux. Fr. Pat. 401,495, July 24, 1908.

THE material to be pressed is contained in the flexible impermeable pockets, *b²*, the sides, *d*, of which are formed of metallic gauze. Two such pockets are placed in the box or frame, *a*, the upper and lower faces of which consist of perforated plates, the other sides being solid plates. The whole is clamped together and water is forced by a pump through the openings, *a²*, *a³*, into the space between the pockets. The material is pressed towards the perforated plates through which the liquid

portion passes. The amount of pressure exerted by the water upon the material is proportional to the resistance offered by it.—W. H. C.

Distilling apparatus. H. L. F. Mariolle. Fr. Pat. 401,587, July 30, 1908.

THE claim is for a combination of stills, condensers, extractors, liquid reservoirs and an air pump in such a way that a series of successive distillations or extractions with recovery of the solvent can be carried out in the same group of apparatus. The operations can be carried out either *in vacuo*, or under atmospheric or increased pressure, and in the case of liquids whose vapours form explosive mixtures with air, the whole of the latter is abstracted and replaced by the vapour of the solvent.—W. H. C.

Centrifugal separator for removing solids or liquids from air or gases. K. Michaelis. Fr. Pat. 401,693, April 6, 1909.

THE gas is passed into one end of the hollow shaft of a centrifugal machine provided with conical baffle-plates and flows through perforations in the shaft, which has a cross partition near its central point, into the spaces between the baffle-plates. The solid and liquid particles glide along the surfaces of the plates and are discharged at the periphery of the drum into the surrounding casing. The cleaned gas leaves the apparatus, flows back into the hollow shaft beyond the partition, and is discharged from the end of the same.—W. H. C.

Chemical reactions; Process for carrying out — [under pressure]. F. Wolfson. Ger. Pat. 214,885, Jan. 18, 1908.

THE reacting substances are mixed to form a stiff mass, with or without addition of an inert material. The mass is coated with paraffin wax, or the latter may be added previously, and then rendered electrically conductive by rubbing graphite over its surface, after which it is coated electrolytically with a deposit of copper or other metal, of a thickness capable of resisting the pressure developed by the chemical reaction. The coated mass is then heated to bring about the reaction, and after cooling, the metal casing may be removed or opened by filing, &c., or by the action of acid.—A. S.

Latent heat of vaporisation of liquids; Process for the regeneration and utilisation of the —. E. Nobel and S. Bessonoff, St. Petersburg. Eng. Pat. 20,921, Oct. 3, 1908.

SEE Fr. Pat. 395,108 of 1908; this J., 1909, 357.—T. F. B.

Reverberatory furnace with separate dust chambers and regenerating chambers arranged in pairs. E. Kirehberg, Dortmund, Germany. Eng. Pat. 21,095, Oct. 6, 1908. Under Int. Conv., Oct. 7, 1907.

SEE Fr. Pat. 388,154 of 1908; this J., 1908, 889.—T. F. B.

Saturating device for liquids. C. E. Vallery, Besancon, France. Eng. Pat. 5250, March 4, 1909.

SEE Fr. Pat. 397,752 of 1909; this J., 1909, 898.—T. F. B.

Absorbent products from sawdust or similar material; Manufacture of —. Comp. Indus. des Alcools de l'Ardèche, Paris. Eng. Pat. 9147, April 17, 1909. Under Int. Conv., June 18, 1908.

SEE Fr. Pat. 400,737 of 1908; this J., 1909, 1024.—T. F. B.

II.—FUEL, GAS, AND LIGHT.

Coal mines; Dust in —. J. Virgin. Eng. and Min. J., 1909, 88, 734.

THE author has experimented with common salt and calcium chloride for the damping of coal dust in mines. Half a ton of dry powdered salt was sprinkled on the roof walls and floor of an 8 ft. wide level, for a distance of 500 ft. In 24 hours the coal dust was damp and

remained so for more than a month. Calcium chloride was found to be still more efficient but also more expensive.

—F. R.

Liquid fuel and its economic aspects. Introductory Lecture, Sir John Cass Technical Inst., Oct. 11, 1909. By J. S. S. Brame.

THE use of liquid fuel for power purposes has within recent years attracted much attention in this country. It is only within comparatively recent times that great advances have been made in its utilisation in internal combustion engines, a use which has had far-reaching results.

As a fuel for steam raising, oils of high calorific value, cheapness, and high flash point are demanded, whilst for internal combustion engines, oils of high volatility are generally requisite in order that they may readily form explosive mixtures with air in the cylinder. For external combustion of oil-fuels, some spraying or "atomising" device is now almost universally adopted, some systems depending on steam injection, others on air, and another type, which is rapidly finding extended use especially for marine purposes, on the spraying action obtained through the oil being forced under pressure through suitable small orifices in the burner. To obtain complete and smokeless combustion great attention has to be paid to the furnace arrangements, and early troubles largely arose from lack of proper attention to this point. Smokeless combustion can now be ensured. Briefly, the advantages of liquid fuel over coal may be summarised as: superior evaporative power to that of coal in the ratio of 1·6 to 1, ease of handling, facility it affords for stowing on ships in situations where coal could not possibly be stored, less space required than for coal, one ton of oil requiring only some 38 cubic feet, whilst coal requires some 43 cubic feet per ton. There are also numerous other minor advantages.

The total oil supplies of the world, taking the figures for 1907, amounted to 34,569,500 tons, which in terms of coal, since it has such superior calorific value, would be equivalent to 51,854,250 tons of coal, or only one-fifth of the coal output of this country alone. Only a portion of the crude petroleum is suitable for fuel. Liquid fuel therefore cannot compete with coal, and is not a fuel for general use, but for employment in special cases.

For use in internal combustion engines the lighter petroleum distillates are almost universally employed. Our annual importation of petrol has now reached the total of some 33,500,000 gallons. By the introduction of the spray carburettor a heavier grade of petrol can now be utilised, a factor of considerable economic importance as regards supplies. Further, since the calorific value of petrols of varying gravity is practically the same per unit weight (20,000 British Thermal Units) it follows that, as they are bought by volume, the heavier grades are more economical. One important point with all engines using petroleum oils is that high compressions are out of the question, since at little over 4·5 atmospheres there is a risk of premature ignition, hence the efficiencies obtained are low. As petrol substitutes, the claims of benzol and alcohol must be considered. Benzol is produced in very large quantities from both gas and coke-oven tar, and its present price is low, about 6½d. per gallon. The calorific value per unit weight is 18,540 British Thermal Units, but per unit volume, owing to its higher gravity, it has a higher value than many petrols. In practice benzol gives most excellent results without any special alteration of the carburettor designed for petrol. A 10 h.p. 6 cylinder Napier having covered 22·65 miles per gallon of benzol as against 18·14 miles on petrol. Slight trouble may be anticipated in very cold weather, but usually there is no difficulty in starting the engine if a little petrol is first put through the carburettor. Alcohol, the only fuel which we can actually manufacture from materials derived from other sources than coal, peat, or petroleum, is of special interest. The importance of alcohol and the great aid which its production on a large scale would give to agriculture, has led to the possibilities of its use being carefully studied by Commissions in Germany, France, and America. For motor use it has many

advantages over petrol or benzine: it is far less inflammable, and if a fire does arise, it can more easily be extinguished. Its combustion leaves no evil-smelling products: engines run more quietly on alcohol, and it will stand higher compressions in the cylinder, thereby giving such greater efficiency that the effect of its low calorific value is almost counterbalanced. For equal weights the calorific value of petrol to alcohol is 20,000 to 11,000 British Thermal Units, a ratio of 1·8 to 1, but if considered by volume, the ratio is reduced to 1·6 to 1. Since the thermal efficiency of alcohol is greater than petrol in the ratio of 3 to 2, it is evident that volume for volume the same power can be obtained from alcohol as from petrol. At present the cost of alcohol is prohibitive, and although in seasons when a heavy yield of raw material—chiefly potatoes—is obtained, the cost of production is comparatively low, yet with charges such as are necessarily imposed through Revenue supervision, quite independent of duty, it is unlikely that it can for many years reach the position of a commercial fuel. As pointed out by Lewes, for use in submarines, alcohol would be an ideal fuel on account of its great safety.

Vertical retorts; The Glover and West — at St. Helens. H. G. Colman. J. Gas Lighting, 1909, 108, 42. (See this J., 1909, 829).

THE results of two additional tests are given below:—

	I.	II.
Kind of coal	Silkstone	Arley Mine
Locality	Yorkshire	Wigan
Percentage of ash in coal	5·95	3·58
Percentage of moisture in coal ..	1·64	1·39
Yield of gas in cub. ft. per ton. .	12,435	12,145
Average illuminating power, in candles	16·19	15·22
Calorific power in B. Th. U. gross	584·9	576·2
Calorific power in B. Th. U. net ..	522·0	516·3
Average composition of the gas—		
Carbon dioxide	1·10	1·15
Unsaturated hydrocarbons ..	2·70	2·45
Oxygen	0·20	0·15
Carbon monoxide	7·30	7·30
Methane	32·30	33·90
Hydrogen	53·75	51·65
Nitrogen	2·40	3·25
Yield of coke in cwt., per ton, moist	15·3	15·8
Yield of coke in cwt., per ton, dry	13·3	13·9
Percentage of ash in coke	9·1	5·87
Percentage of moisture in coke ..	12·5	12·05
Fuel used in gas generator, as percentage of dry coke	13·4	12·2
Yield of tar in gallons per ton ..	12·4	10·74
Sp. gr. of tar	1·084	1·075
Quality of tar	Much thinner than that from the same coal carbonised in horizontal or inclined retorts	Comparatively thin.
Composition of tar—		
Percentage by weight of light oils distilling up to 170° C. .	6·7	5·8
Percentage of middle oils distilling from 170°—270° C. .	21·7	23·1
Percentage of heavy oils distilling from 270°—350° C. .	22·5	27·8
Percentage of pitch remaining at 350° C.	48·5	42·7
Percentage of naphthalene ..	6·9	6·7
Percentage of free carbon ..	3·6	3·8
Yield of ammonia equal to lb. ammonium sulphate per ton ..	20·1	24·2
Yield of cyanogen as Na ₂ Fe(CN) ₆ ·10H ₂ O, lb. per ton	5·67	5·64
Total sulphur in gas after purification with oxide only, grains per 100 cub. ft.	27	30·2
Naphthalene in purified gas, grains per 100 cub. ft.	3·3	3·3

Determining carbon monoxide in mine gas. Weiskopf. See XXIII. Inorg. Quant.

PATENTS.

Peat; Apparatus for producing fuel and gas from — W. L. Shepard, Elmwood, Conn., Assignor to H. J. Wickham, Manchester, Conn. U.S. Pat. 936,049, Oct. 5, 1909.

THE apparatus consists of one or more retorts, each of which is formed of a shell provided with a lining of fire-resisting material. The upper end of each retort is closed with a loosely fitting cover, and a door, carrying a burner for heating the interior of the retort before the introduction of the peat, is hinged to the lower end. Gas passes through outlet pipes leading from the upper portions of the retorts to a hydraulic main, and valves are provided whereby each retort can be isolated from the main. A washer is connected with the main, and superheaters are connected with the washer by pipes in which valves are placed so that either superheater can be utilised without using the other. The superheaters are connected by pipes with a gas storage tank.—W. C. H.

Peat; Direct and rapid conversion of — into small charcoal. X. M. Roux. Fr. Pat. 401,419, July 22, 1908.

THE object of the invention is to obtain peat charcoal in the form of small pieces similar to ordinary wood charcoal. The raw peat is pressed to remove about three-fourths of the moisture present, and is then disintegrated and pressed into briquettes of the desired size and shape. These briquettes are carbonised in closed retorts at a temperature varying from 250° to 350° C. without further drying. Thus, the carbonisation results in the production of gas, tar, and ammoniacal liquor, collected in the usual way, and also in the formation of a carbonaceous residue consisting of small pieces of carbon, similar to wood charcoal obtained in wood retorts. The whole process can be carried through in half-an-hour.—A. T. L.

Coke oven. Soc. Anon. d'Ougrée-Marihaye. Fr. Pat. 401,451, March 31, 1909. Under Int. Conv., June 2, 1908.

THE oven comprises a series of coking chambers *a* (see Fig. 2), with hollow dividing walls, *b*, forming heating flues.

Fig. 1.

Fig. 2.

towards the main flues, as shown in Fig. 2, in order that the velocity of the gases may be uniform. The gas

supply is distributed by mains, *j*, *j*¹, *j*², and pipes, *n*, *n*¹, *n*². When the currents are reversed in the regenerators, the heating gases pass in the direction opposite to that indicated in Fig. 1, the gas being distributed to another set of burner orifices, *o*, from the pipes, *p*, *p*¹, *p*². The walls of the flues, *c*, *d*, are constructed of special bricks so that the walls separating the flues, *c*, *d*, from the chambers, *a*, are thinner than the walls separating the flues, *c*, *d*, from one another, but these latter walls are of a material of greater conductivity.—A. T. L.

Vertical [gas] retorts; Charging of — R. Dempster and Sons, Ltd., and H. J. Toogood, Elland, Yorks. Eng. Pat. 19,437, Sept. 16, 1908.

THE patent relates to the charging of vertical gas retorts in such a manner as to facilitate the escape of gas during that stage of the distillation when the charge becomes more or less plastic. The unscreened coal is delivered in a relatively thin stream down one side (or around the sides) of the retort, the differing velocities and slipping tendencies of the "slack" and "nuts" causing a column of the latter to form on the opposite side (or in the centre) of the retort.—W. E. F. P.

Water-gas; Manufacture of — A. G. Glasgow, Richmond, Va., U.S.A. Eng. Pat. 17,603, Aug. 21, 1908.

IN water-gas plant comprising generators blown alternately with air and with steam, and steam-operated blowing engines, pumps, exhausters, etc., the exhaust steam from the engines is collected in a main provided with a relief valve, and is used for the steam-blow in the generators, which are connected by valved branch-pipes with the exhaust-steam main.—A. T. L.

Gases [water-gas]; Treatment of — for removing carbon monoxide therefrom and replacing it by hydrogen. G. W. Johnson, London. From Chem. Fabr. Griesheim-Elektron, Frankfurt, Germany. Eng. Pat. 2523, Feb. 2, 1909.

WATER-GAS heated to about 500° C. is passed together with steam through a reaction chamber containing lime or calcium hydroxide. The following reaction takes place: $\text{Ca(OH)}_2 + \text{CO} = \text{CaCO}_3 + \text{H}_2$, with evolution of heat, and the reaction chamber is cooled so that the temperature does not exceed 500° C., or the temperature at which calcium carbonate commences to dissociate. The reaction may be accelerated by the addition of a metal, for example, 5 per cent. of iron powder, in the reaction chamber.—A. T. L.

Gas producers; Rotary grate for — Gütchoffnungshütte, Aktienverein für Bergbau und Hüttenbetrieb, Oberhausen, Germany. Eng. Pat. 14,947, June 26, 1909. Under Int. Conv., Sept. 30, 1908.

THE invention relates to a rotary grate in which the two concentrically arranged parts rotate in opposite directions. The inner part is cylindrical or conical, and carries a circular step-grate mounted eccentrically to the axis of rotation, while the outer part consists of an annular dish. The inner portion is made to rotate more quickly than the outer part, in order to crush the clinker and loosen the charge in the gasifying zone of the producer.—W. E. F. P.

Gas-producers; Apparatus for regulating the supply of steam to — in order to maintain uniformity in the gas produced. L. P. C. Roche, Fr. Pat. 401,530, April 2, 1909.

THE patent relates to gas-producers of the suction type. An annular boiler in the upper part of the producer is employed, and this boiler is provided with heating flues and is capable of generating more steam than is required. The quantity of steam generated is regulated by supplying more or less cold feed-water, the water-level in the boiler being kept constant by an overflow pipe. In order to keep the water-supply constant at the desired rate of feed, the supply is taken from a constant-level tank by means of a down-pipe terminating in a small orifice.—A. T. L.

Gas-producer. A. Fichet and R. Heurtey. Fr. Pat. 401,535, July 27, 1908.

THE producer comprises a cylindrical metal casing, of which the lower part only is lined with refractory material. The fuel column rests directly upon the hearth of the producer. The producer is worked with a blast of hot or cold air, introduced through water-cooled tuyères; the clinker and ash are fused in the lower part of the producer, fluxes being used if necessary, and the fused mass is run off through suitable outlets. A central conical hood in the upper unlined part of the producer throws the descending fuel column outwards, and forms a gas-collecting chamber in the interior of the producer, the gas-outlet pipes being connected to this chamber.—A. T. L.

Gas scrubbers or purifiers. R. V. Farnham, Wemyss Bay, Renfrewshire. Eng. Pat. 28,233, Dec. 28, 1908.

THE apparatus described, which is for use with a suction gas plant, consists of a suitably mounted water wheel or turbine, carrying a series of flat radial blades feathered at their outer ends. The operation of the wheel produces a fine spray of water, through which the gas is made to pass on issuing from the generator.—W. E. F. P.

Controlling or deflecting the flow of flue gases or the like, specially applicable for use in connection with CO₂ recorders. A. E. Carr, Liverpool. Eng. Pat. 20,244, Sept. 26, 1908.

FIG. 1.

A PIPE, 5, extends upwards from the boiler flue into the vessel, 1, as indicated at 3, and the pipe, 7, leading to the carbon dioxide recorder has a branch, 4, which also extends upwards into the vessel, 1. This vessel is filled with liquid and is provided with a cover, 9, which dips into the liquid and forms a seal; the cover is provided with a midfeather, 12. When the cover is in the position shown in section in Fig. 1, and in plan at 12, in Fig. 2, the gases pass from the boiler flue to the main, 7. When it is desired to cut off the connection between the main, 7, and the flue, the cover, 9, is lifted, turned through a right angle and replaced with the midfeather in the position shown by the dotted line in Fig. 2. The cover, 9, may be made longer and be provided with a filter through which the gases are compelled to pass. The filtering material is contained in a cartridge which fits into the filter so as to be easily replaceable.—W. H. C.

Calcium carbide cartridges. A. Barnett, London. Eng. Pats. 19,939, Sept. 22, 1908; 24,679, Nov. 17, 1908; and 2301, Jan. 30, 1909.

CRUSHED carbide is mixed with fine sawdust, and hard wax, linseed oil, and resin, pitch, or other binding material are added; the mixture, heated if necessary, is compressed into a block of suitable size and shape for the carbide chamber of an ordinary acetylene lamp. The block, which may be provided with a central hole, is wrapped in oil paper, tinfoil, or the like, and packed in an outer tin or cardboard box made to fit into the lamp chamber, so as to be removed bodily after use, all mess being thus avoided. Or, the box may be dispensed with, and the cartridge wrapped in paper and then in an outer covering

of capsule metal, tinfoil, or lead foil, so as to be air-tight, and a space may be left between the block and the casing to prevent bursting of the cartridge during use. The ingredients may be mixed in the following proportions:—100 parts of carbide, 18 of sawdust, 10 of hard wax, 2 of linseed oil, and 6 of resin or other binding material; or, 100 of carbide, 10 of hard wax, 2 of linseed oil, and 6 of binding material; or, 100 of carbide, 18 of sawdust, and 10 of resin.—F. SOBN.

Electrical incandescent refractory metal filaments; Process for the prevention of the disintegration of — in a vacuum. Glühlampenwerk Anker, Berlin. Eng. Pat. 19,847, Sept. 22, 1908. Under Int. Conv., Oct. 3, 1907.

PHOSPHORETTED or arseniuretted hydrogen is introduced into the exhausted lamp bulb by placing suitable reagents on the leading-in wires or in the tube through which the lamp is exhausted. These reagents are (1), 1 part of phosphorus and 2 parts of phospham, PN_2H ; (2), 1 part of phosphorus, 1 part of solid phosphoretted hydrogen, P_4H_2 , and 1 part of phospham; (3), 2 parts of solid arseniuretted hydrogen, As_2H_2 , and 1 part of phospham.—A. T. L.

Gas; Apparatus for the manufacture of —. W. H. Morgan and J. Densley, Weston-super-Mare, Assignors to Walls, Ltd., Birmingham. U.S. Pat. 936,144, Oct. 5, 1909.

SEE Eng. Pat. 10,558 of 1908; this J., 1908, 1051.—T. F. B.

Gas and air; Mechanism for the production of a constant mixture of —. F. H. Wolff, Assignor to Selas Ges.m.b.H., Berlin. U.S. Pat. 937,016, Oct. 12, 1909.

SEE Eng. Pat. 25,596 of 1905; this J., 1907, 41.—T. F. B.

Coal gas, water gas, and oil gas, or mixtures of these gases; Process and apparatus for making —. W. H. Morgan, J. Densley, H. Gray, H. J. Walduck, and G. Geering. Fr. Pat. 401,641, April 3, 1909. Under Int. Conv., May 15, 1908.

SEE Eng. Pat. 10,558 of 1908; this J., 1908, 1051.—T. F. B.

Gases generated by dry distillation; Process of purifying —, and of obtaining by-products therefrom. K. Burkheiser, Aix-la-Chapelle, Germany. Eng. Pat. 20,920, Oct. 3, 1908. Under Int. Conv., Oct. 14, 1907.

SEE Fr. Pat. 394,926 of 1908; this J., 1909, 359.—T. F. B.

Carbon bisulphide from gases, particularly coal-gas; Method of removing —. M. Mayer and A. Fehlmann, Karlsruhe, Germany. Eng. Pat. 174, Jan. 4, 1909.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

Methyl alcohol: Purification of — in counter-current rectifying column apparatus. P. Pikoš, Z. angew. Chem., 1909, 22, 2036—2037.

IN apparatus for the rectification of wood spirit, copper is the material almost invariably used for the rectifying columns, condensers, etc., and the still itself, if of wrought iron, is provided with a copper lining. The author, as the result of long practical experience and numerous experiments, states that under the catalytic influence of the copper, considerable quantities of methyl alcohol are lost by oxidation to acetaldehyde, methylal, and formaldehyde. There is always a small quantity of air in the apparatus at the beginning, and further quantities are almost invariably sucked in at intervals during the process, owing to variations of pressure. Although the greater portion of the aldehyde produced escapes, some passes back into the spirit, and can be detected in the form of aldehyde-ammonia, by addition of caustic soda and allowing to stand; frequently also the so-called aldehyde-resin is deposited in the still. The losses are greatest when an alkaline reagent has been added to the crude spirit: the liberated ammonia combines with the aldehyde produced, forming aldehyde-ammonia, which by its strong solvent action, cleans the surface of the copper tubes, vessels, etc., and thus renders the metal more active. Considerable losses of methyl alcohol may also occur in the subsequent operations of treatment of the rectified spirit with sulphuric acid, and oxidation with 5 per cent. permanganate solution, unless great care be exercised. The author recommends that apparatus for the rectification of wood spirit be constructed of aluminium or an aluminium alloy free from copper; or copper with a thick coating of tin, or copper or iron with linings of earthenware or stoneware might be employed, with connecting pipes, etc., of earthenware. Where copper apparatus is used, special care should be taken to prevent sucking-in of air during the process, owing to variations of pressure; and in any case it would appear advisable to effect the rectification in an apparatus working under vacuum.

—A. S.

Petroleum oils: Grozny — rich in paraffin wax. K. Charitschoff, Chem. Rev. Fett-u. Harz-Ind., 1909, 16, 247—248.

It has long been known that the petroleum oils from the western part of the Grozny oil-fields differed considerably from oils from other parts of the fields, and especially in containing a high proportion of paraffin wax. Further investigations have shown that these particular oils only occur in a wedge-shaped patch of the western district, whilst the oils produced to the north and south of this area are intermediate between those rich in, and those free from paraffin wax. The proportion of paraffin wax shows great variations. In determining it the author employed a modification of Zalozecky's method, in which the sample was first freed from asphaltum by treatment with excess of sulphuric acid, so that the paraffin wax subsequently separated was pure and of a pale yellow colour. Heavy petroleum oil containing paraffin wax was first discovered in 1905, in MacGarvey's borings. It had a sp. gr. of 0.906 to 0.919, and on distillation yielded the following fractions:—Up to 110° C. 12.12; 110—150° C. 0.75; 152°—273° C. 22 (with sp. gr. 0.8048, and flashing point 40° C.); and residue 66.25 per cent. (with sp. gr. 0.9246 and flashing point, 120° C.). On treatment of the residue with sulphuric acid in excess, a final residue of 36.9 per cent. was obtained, and this contained 8.38 per cent. of paraffin wax (2.35 per cent. on the crude oil). When distilled in a current of steam the residue yielded the following fractions:—From 200°—250° C. 10 per cent. (with sp. gr. 0.840 and flashing point 80° C.); 250°—275° C. 12.6 per cent. (with sp. gr. 0.856 and flashing point 100° C.); 275°—295° C. 13.8 per cent. (with sp. gr. 0.875 and flashing

point 130° C.); 295—325° C. 5.8 per cent. (with sp. gr. 0.889 and flashing point 160° C.); 325°—360° C. 1.3 per cent. (sp. gr. 0.891); and residue, 54.3 per cent. (sp. gr. 0.940). The first three fractions were very fluid, the fourth viscous, and the fifth semi-solid. The residue was hard, brittle, and of an asphaltic character.—C. A. M.

Mineral oil: Refining — by the dry process. F. Schulz, Petroleum, 1909, 5, 86—90.

THE author finds that all the organic acids present in petroleum distillate can be completely eliminated by agitation with dry calcium hydroxide, the treatment also removing the acids left after the treatment with concentrated sulphuric acid. About 1½ to 2 per cent. of calcium hydroxide is used, after the acid treatment, agitation being continued for about 15 minutes. In practice it will be advisable to pass the entire contents of the agitator through a filter-press, without previous subsidence, and then put the still somewhat cloudy filtrate through an ordinary filter. In the case of highly viscous oils, the use of a centrifuge is suggested for separating the lime sludge from the clarified oil. The lime treatment is said to have no injurious influence on the charring of the wick, or on the colour of the finished oil.—C. S.

Mineral oils in Spain; Tariff classification of —. Board of Trade J., Oct. 28, 1909. [T.R.]

A ROYAL ORDER, dated the 11th October, contains the following provisions:—

1. Note 3 to the Tariff is to be altered in the sense that lubricating oils included under Tariff No. 23 must contain less than 10 per cent. by volume of tar.

2. Those oils are to be dutiable under Tariff No. 20 which leave, on distillation at 300° C., residues to the amount of more than 80 per cent., or emit inflammable vapours below 150° C.; which, treated with concentrated sulphuric acid, rise more than 3° C. in temperature; which contain more than 10 per cent. by volume of tar, or leave a solid residuum greater than 3 per cent. of the distilled liquid.

3. Oils which do not satisfy the foregoing conditions, and are not included under Tariff Nos. 21 or 22, are to be dutiable as lubricating oils under Tariff No. 23.

Nos. 20—23 of the Spanish Tariff are as follows:—

Petroleum and mineral oils, which leave, on distillation at 300° C., residues to the amount of:—

No.		Duty.
		Pes. Cts.
20	More than 80 per cent.	100 kilos. 30 00
21	From 20 to 80 per cent. inclusive	" 25 00
22	Less than 20 per cent.	" 37 00
23	Oleomaphtha, mineral lubricating oils, vaseline, and mixtures of these products with animal or vegetable oils or fats	" 40 00

NOTE.—25.15 pesetas = £1 sterling.

Fats: Detection of — in vaseline. A. Ferraro, L'Union pharm., 1909, 50, 400.

A REAGENT is prepared by adding ammonia, drop by drop, to a saturated aqueous solution of acid fuchsine, until the colour disappears. Twenty grms. of vaseline are intimately mixed in a porcelain capsule, with 4 or 5 grms. of the reagent. In presence of animal or vegetable fats, a more less intense rose tint will be evident.—J. O. B.

PATENTS.

Nitrobenzene: Process of making —. Saccharin-Fabr. A.-G. vorm. Fahlberg, List, und Co. Fr. Pat. 401,679, April 5, 1909.

IN the preparation of nitrobenzene from benzene, sulphuric acid, and an alkali nitrate, the sulphuric acid should be slowly added to a mixture of benzene and alkali nitrate in such a manner that a layer of a solution of alkali bisulphate is formed on the surface of the mixture as rapidly

and at as low a temperature as possible; in this way the nitration proceeds regularly. For example, 115 kilos. of sodium nitrate and 35 kilos. of benzene are heated to 60°–80° C. in a vessel provided with a stirrer: 150 kilos. of 90–96 per cent. sulphuric acid are slowly added, with stirring, when the temperature will rise to about 100° C. A further quantity of 65 kilos. of benzene is now added gradually, agitation being continued until the mixture can separate readily into two layers. The product is now heated for a short time and the nitrobenzene separated and purified in the usual manner. The yield is said to amount to 148 kilos. of pure nitrobenzene. The aqueous residue deposits sodium bisulphate on cooling, and the mother liquor, which contains a small quantity of nitric acid, may be added to the sulphuric acid for a subsequent nitration.—T. F. B.

Tar, pitch, asphaltum, and analogous substances; Process for purifying — by extraction with solvents, with simultaneous recovery of pure carbon. Chem. Fabr. Lindenhof C. Weyl und Co. Ger. Pat. 213,507, July 31, 1908.

It has been proposed to treat tar, pitch, asphaltum, etc., with hydrocarbons and carbon bisulphide to facilitate the separation of the carbon; the separation is, however, incomplete, since aniline, pyridine, and other bases extract further quantities of bituminous constituents from the solid residue. Extraction with aniline and pyridine is costly, so it is proposed to use phenols or phenolic constituents of tars for the purpose. The extraction may be performed by the phenol alone, or it may be preceded by an extraction with hydrocarbons. By filtration of the mixture of tar or other substance with phenol, and washing with a further quantity of phenol and then with alkali and water, a pure carbon is said to be obtained. The phenol is separated from the extract by treatment with alkali and precipitation of the solution with carbon dioxide. The bituminous extract obtained has a considerably higher softening-point than that produced by extraction with hydrocarbon alone.—T. F. B.

Paraffin wax for candles or other purposes; Manufacture of —. R. H. F. Finlay, Belfast. Eng. Pat. 8768, April 13, 1909.

THE stearine commonly added to paraffin wax to increase its strength and prevent crystallisation in the moulds is partially or completely replaced by a small quantity of a soap or soaps. These may be salts either of alkali metals or of other inorganic bases with fatty or allied acids.—C. A. M.

Sulphuric acid and oils; Process for the recovery of — from waste acid of all kinds. G. Stolzenwald. Ger. Pat. 213,589, May 23, 1908. Addition to Ger. Pat. 212,000, Aug. 6, 1907.

IF the waste acid contains much tarry or resinous matter, it is diluted with water, and heated in covered lead pans, the vapours being passed to a condenser to recover volatile oils. When most of the volatile oils have distilled over, the residual acid is run into a settling vessel and allowed to cool, when the greater part of the resinous and tarry matters rises to the surface and forms a solid cake. After removing this, the acid is treated in the apparatus described in the main patent (this J., 1909, 1081).—A. S.

Improving tar oil [for preserving wood, etc.]. Ger. Pat. 213,715. See IX.

IV.—COLOURING MATTERS AND DYESTUFFS.

Rosaniline hydrochloride and Crystal Violet; Decomposition of the leucosulphonic acids of — in aqueous solution. J. H. Kastle. Amer. Chem. J., 1909, 42, 293–300.

ACCORDING to Hantzsch and Osswald (this J., 1900, 236), the compound obtained by the action of sulphur dioxide on pararosaniline hydrochloride has the constitution,

and these workers gave it the name pararosaniline hydrochloride leucosulphonic acid; it is partially decomposed by a current of carbon dioxide even in the cold, pararosaniline hydrochloride being regenerated. The author has now investigated the nature of the decomposition of the leucosulphonic acids of rosaniline hydrochloride and Crystal Violet in aqueous solution. Dilute solutions (about 0.1 per cent.) of rosaniline hydrochloride and Crystal Violet were decolorised with sulphur dioxide. On evaporation, the decolorised solutions yield the original dyestuffs, and on boiling for a long time, they become permanently coloured; if, however, they are only boiled for a short time so that all the sulphur dioxide is not removed, the colours appear and persist in the hot solutions but disappear on cooling; the changes may be repeated several times on the same solution by alternate heating and cooling. The author has also shown that the decomposition of the leucosulphonic acids of the dyestuffs of the pararosaniline type in aqueous solution is a reversible process, and that atmospheric air does not cause the above-mentioned changes of colour. As to whether the change is one of simple or of hydrolytic dissociation remains to be decided; the author inclines to the latter view.—L. E.

Ethylene derivatives containing nitrogen. G. Busignies. Comptes rend., 1909, 149, 348–350.

By the action of the Grignard reagent on amino- or alkylamino ketones the author has prepared a number of ethylene bases. The following were obtained by using, on the one hand, methyl, ethyl and isoamyl iodides and benzyl chloride and, on the other hand, dimethylaminobenzophenone, Michler's ketone, and tetraethyldiaminobenzophenone: *p*-dimethylaminodiphenylethylene, m.pt. 47° C.; *p*-dimethylaminodiphenylpropylene, m.pt. 91° C.; *pp*-tetramethyldiaminodiphenylethylene, m.pt. 115° C.; *pp*-tetramethyldiaminodiphenylpropylene, m.pt. 99° C.; isoamylidenetetramethyldiaminodiphenylmethane, m.pt. 61° C.; *pp*-tetraethyldiaminodiphenylethylene, m.pt. 102° C.; and *pp*-tetraethyldiaminodiphenylpropylene, m.pt. 56° C. These ethylene derivatives combine with 2 atoms of hydrogen to give the corresponding saturated compounds.—J. C. C.

Leuco bases and dyestuffs derived from diphenylethylene; New series of —. P. Lemoult. Comptes rend., 1909, 149, 606–608. (See also Fr. Pat. 382,187; this J., 1908, 936).

THE substances described by Busignies (preceding abstract) are true leuco-bases for on oxidation in acid solution (best with sodium nitrite) they give the following colours: tetramethyldiaminodiphenylethylene, green; tetraethyldiaminodiphenylethylene, green; tetramethyldiaminodiphenylpropylene, blue; tetraethyldiaminodiphenylpropylene, blue; tetramethyldiaminodiphenylphenylethylene, greenish blue, and tetraethyldiaminodiphenylphenylethylene, blue green. These colours can be fixed on tannin-mordanted cotton when sodium nitrite is added to the bath containing the fibre and leuco-base.—J. C. C.

Hydroxyazo-derivatives obtained from aminomethylene-catechol. E. Mameli. Gaz. chim. ital., 1909, 39, II., 314–321.

By combining the diazo-derivative of aminomethylene-catechol, $\text{CH}_2\text{O}_2 : \text{C}_6\text{H}_3.\text{NH}_2[\text{CH}_2\text{O}_2 : \text{NH}_2 \quad 1:2:5]$, with phenols or their derivatives, hydroxyazo-compounds are obtained, which act as acid dyestuffs. They are specially suitable for dyeing wool and silk in a bath containing sulphuric acid and sodium sulphate; and in a lesser degree for dyeing artificial silk in a bath containing acetic acid. They also dye cotton mordanted with tannin and tartar emetic in a bath containing acetic acid. The shades produced are fast to washing and light, especially on wool and silk. The dyestuffs from phenol, *o*- and *p*-resol, *α*- and *β*-naphthol, and salicylic acid were prepared. Of these,

the products from phenol and α -naphthol possessed the greatest colouring power, the latter dyeing wool dark red in an acid bath.—A. S.

Tri-indylmethane dyestuffs. A new class of dyestuff of biochemical importance. A. Ellinger and C. Flamand. *Z. physiol. Chem.*, 1909, **62**, 276—286.

ELLINGER found in 1906 (*Ber.*, **39**, 2519) that when β -indolaldehyde is heated with moderately concentrated acids a red dyestuff is obtained. The authors have investigated this more fully, and find that the dyestuff prepared by the use of 50 per cent. sulphuric acid dyes wool and silk from alcoholic acetic acid solution in red-brown shades inclining to violet. As this reaction is accompanied by the formation of formic acid and sulphur dioxide, it seemed likely that the dyestuff had been formed by condensation of indolaldehyde with indole and subsequent oxidation and salt formation, and that it consisted of a tri-indylmethane derivative. This was proved by its synthesis from indole, chloroform and alcoholic potash. The dye-base has therefore the formula, $\text{HO} \cdot \text{C}(\text{C}_6\text{H}_5\text{N})_3$, and the salt the formula,

On heating the dyestuff with water under pressure, it is decomposed into indole and indolaldehyde. The authors think it probable that uroscine and "seatole red" may belong to this new series.—J. C. C.

ERRATUM.—This Journal, 1909, page 1082, col. 1, line 30 from top, for "85°—87° C." read "64°—65° C."

PATENTS.

Azo dyestuff. M. Kahn and A. Ossenbeck, Assignors to Farbenfabr. vorm. F. Bayer and Co., Elberfeld, Germany. U.S. Pat. 935,031, Sept. 28, 1909.

THE azo dyestuffs obtainable from dinitro-orthoamino-m-cresol and 2-arylamino-5-naphthol-7-sulphonic acids are dark powders, soluble in water with a violet colour, and dye wool in violet shades which are converted into fast black shades by chroming.—F. M.

Azo dyestuffs. P. Volkmann, Assignor to Farbenfabr. vorm. F. Bayer and Co., Elberfeld, Germany. U.S. Pat. 935,829 and 935,830, Oct. 5, 1909.

DIAZOTISED toluidines or toluidinesulphonic acids are combined with 1-sulphoaryl-3-methyl-5-pyrazolones. The dyestuffs from *p*-toluidine and 2-toluidine-5-sulphonic acid are especially claimed. All the products are soluble in water, and dye wool yellow shades.—T. F. B.

Azo dyestuff. M. Kahn, Assignor to Farbenfabr. vorm. F. Bayer and Co., Elberfeld, Germany. U.S. Pat. 936,456, Oct. 12, 1909.

CLAIM is made for the dyestuff obtained from diazotised *p*-aminochrysoidine and 1:8-aminonaphthol-4:6-disulphonic acid. It forms a dark powder giving a blue solution with concentrated sulphuric acid and dyeing cotton in blue shades which when developed with diazotised *p*-nitraniline are changed to black.—J. C. C.

Tetrazo dyestuff; Orange to red —. A. Schedler, Assignor to Soc. Chem. Ind. in Basel, Switzerland. U.S. Pat. 936,367, Oct. 12, 1909.

CLAIM is made for the tetrazo dyestuffs obtained by combination of one molecule of the tetrazo derivative of a diamine of the general formula, $\text{NH}_2 \cdot \text{R}' \cdot \text{X} \cdot \text{R} \cdot \text{NH}_2$, with two molecules of a component one of which is a molecule of an aminoaryl-5-pyrazolone derivative. The products are brownish-yellow to brown powders dyeing unmodanted cotton in orange-yellow to orange-red shades which, when further diazotised and developed with β -naphthol, yield orange to red tints fast to washing.—J. C. C.

Mongazo dyestuffs; Production of new —. Act.-Ges. f. Anilinfabr. Fr. Pat. 401,006, March 15, 1909.

THE new dyestuffs are obtained by combining diazo-compounds with 3-amino-4- and -2-cresols ($\text{CH}_3 : \text{OH} : \text{NH}_2 = 1:4:3$ and $1:2:3$) in acid solution. They dye unmodanted wool from an acid bath and are specially suitable for subsequent chroming. They can also be used as intermediate products for the production of polyazo dyestuffs. The azo-dyestuff prepared from diazotised *p*-nitraniline and 3-amino-4-cresol is a red powder with a green, metallic lustre. When *p*-chlor-anilinesulphonic acid is used instead of *p*-nitraniline, the resulting dyestuff forms a red powder with a green metallic lustre; it dyes wool in brown shades which change to brownish-red on chroming. The dyestuff obtained by combining diazotised sulphanilic acid with 3-amino-2-cresol is a red powder; it dyes wool in brownish-orange shades which become brown on chroming.—J. C. C.

Yellow dyestuff; Production of a —. L. Cassella and Co. Fr. Pat. 401,379, July 21, 1908.

By condensing dinitrostilbenedisulphonic acid with formaldehyde in the presence of sodium hydroxide, a dyestuff is produced which dyes cotton direct in yellow shades fast to washing, light, and chlorine.—J. C. C.

Halogenated indigos and intermediate products serving for their manufacture; Production of —. Badische Anilin und Soda Fabrik. Fr. Pat. 401,506, April 1, 1909. Under Int. Conv., Dec. 12, 1908, and March 9, 1909.

NEITHER the halogen derivatives of phenylglycine nor of phenylglycine-*o*-carboxylic acid can be transformed into halogenated derivatives of indigo, because the halogens are eliminated in the necessary operations. It is now found, however, that the acid or neutral esters of halogenated phenylglycine-*o*-carboxylic acids can be transformed into the corresponding halogenated indigos without loss of halogen. Example 1: Dichloroanthranilic acid (m. p. 222°—224° C.) is treated with formaldehyde and the product converted into *o*-cyanomethyldichloroanthranilic acid by digestion with potassium cyanide. On hydrolysis of this nitrile, 4:6-dichlorophenylglycine-2-carboxylic acid, identical with the acid produced by chlorinating phenylglycinecarboxylic acid, is obtained. Example 2: Dibromoanthranilic acid, m. pt. 245°—248° C., is prepared in a similar way from dibromoanthranilic acid, m. pt. 225° C. Example 3: By the same process tetrachloroanthranilic acid is converted into tetrachlorophenylglycine-*o*-carboxylic acid, m. pt. 198° C. Example 4: By the same series of operations anthranilodiacetic acid, $\text{CO}_2\text{H} \cdot \text{C}_6\text{H}_4 \cdot \text{N}(\text{CH}_2\text{CO}_2\text{H})_2$, identical with the acid obtained from anthranilic acid and chloroacetic acid, is prepared either from *o*-cyanomethylantranilic acid or phenylglycine-*o*-carboxylic acid. Example 5: By chlorinating dimethylphenylglycine-*o*-carboxylate in benzene solution, dimethyldichlorophenylglycine-*o*-carboxylate is produced. Example 6: The same ester, m. pt. 78° C., is obtained by methylating 4:6-dichlorophenylglycine-2-carboxylic acid. Example 7: On treating the ester described in the preceding example with sodium in toluene solution, methyl 5:7-dichloroindoxylcarboxylate,

m. pt. 195° C., is produced, and on heating this with dilute aqueous sodium hydroxide, 5:7:5':7'-tetrachloroindigo

is obtained. This is a blue powder which dyes cotton and wool in bright blue shades. Example 8: Methyl 7-chloro-5-bromoindoxylcarboxylate is prepared by treating methyl 4-bromo-6-chlorophenylglycine-2-carboxylate with sodium methoxide, and on treatment with aqueous sodium hydroxide it yields 7:7'-dichloro-5:5'-dibromoindigo which dyes cotton in bright greenish-blue shades.—J. C. C.

Azo dyestuff; Manufacture of a new —. P. A. Newton, London. From Farbenfabr. vorm. F. Bayer und Co., Elberfeld, Germany. Eng. Pat. 24,600, Nov. 16, 1908.

SEE Fr. Pat. 396,381 of 1908; this J., 1909, 565.—T. F. B.

V.—PREPARING, BLEACHING, DYEING, PRINTING AND FINISHING TEXTILES, YARNS, AND FIBRES.

Nigrisin; The production of — and similar dyestuffs on the fibre. J. Brandt, Sealed Note No. 1027, dated Mar. 16, 1898, and Report thereon by R. Federmann. Bull. Soc. Ind. Mulhouse, 1909, 79, 251—254.

NIGRISIN is produced when aqueous or alcoholic solutions of nitrosodimethylaniline hydrochloride are boiled. Upon printing a thickened solution of this salt upon cotton and then steaming, a yellow shade is obtained but no decomposition of the nitroso compound takes place, whereas in the presence of an organic acid a grey (similar in shade to that given by Nigrisin upon un mordanted cotton) is produced on steaming. By replacing the organic acid by tannin steaming, fixing with tartar emetic and washing, a deep rich grey is obtained. Level shades are obtained by dyeing in a weak bath of nitrosodimethylaniline salt and tannin, drying in the hot flue, steaming, and fixing with tartar emetic; by reduction the nitroso compound is converted into dimethylparaphenyl-

caediamine, so that by printing with suitable reducing pastes, white and colour discharge effects upon a grey ground are obtained.—F. M.

PATENTS.

Artificial fibres from cellulose; Manufacture of —. W. P. Dreaper, Felixstowe. Eng. Pat. 20,316, Sept. 28, 1908.

SOLUTIONS of cellulose in the ordinary cuprammonium solution will give good filaments when squirted into concentrated alkaline solutions to which have been added organic substances which materially increase the viscosity of the solutions. For example a 10 per cent. solution of glucose containing 10 per cent. of sodium hydroxide may be used for spinning with a 10—12 per cent. solution of cellulose. The temperature of the precipitating bath may be raised even up to 70° C. Where such a bath is used, the cellulose or hydrocellulose is dissolved in aqueous solutions containing either zinc chloride or copper carbonate dissolved in ammonia.—P. F. C.

Cellulose and albuminoid bodies [Artificial silk]; Process of strengthening —. X. Eschaliar. Fourth Addition, dated March 31, 1909, to Fr. Pat. 374,724, April 24, 1906 (this J., 1907, 821).

THE reagents used for the "sthenosage" of artificial silk, etc., may be dissolved in other media than water, e.g. acetone, alcohol, glycerin, etc. The use of acetone is particularly advantageous, since it dispenses with the usual process of dehydration. The dry silk is introduced into a bath composed of 150—200 parts of acetone, 5—20 parts of 40 per cent. formaldehyde and 0.5—0.15 part of sulphuric acid of 66° B. or hydrochloric acid of 23° B. These quantities are sufficient for treating 10 parts of silk. The whole is boiled for 3—5 hours under a reflux condenser, the silk being completely immersed. The silk is then washed with water and dried. When required for dyeing, the silk is subsequently steeped in an alkaline solution of a hypochlorite, containing 30—50 grms. of sodium hydroxide and 3—5 litres of available chlorine per litre. Other acids may be used, if desired, instead of the mineral acids.—J. F. B.

Artificial threads; Preparation of stable solutions for obtaining —. P. Friedrich. First Addition, dated Mar. 23, 1909, to Fr. Pat. 400,321, Feb. 13, 1909. Under Int. Conv., Mar. 30, 1908.

ACCORDING to the principal patent (see Eng. Pat. 4104 of 1909; this J., 1909, 934), carbohydrates or gums were added to the solutions of cellulose. Solutions having the same properties can be more directly obtained by preparing the cellulose solutions from those plants which contain both carbohydrates and cellulose. The outside layers of the rice plant, for example, give good results if they are first treated with alkalis and then bleached and washed before being dissolved in a cuprammonium solution.—P. F. C.

Colloidal solutions of ammoniacal cupric hydroxide for the manufacture of threads and filaments of cellulose; Preparation of —. Soc. Anon. Le Crinoid. Fr. Pat. 401,741, Aug. 6, 1908.

As described in Fr. Pat. 362,986 of 1906 (this J., 1906, 808) colloidal ammoniacal cupric hydroxide can be separated from the other constituents of a cuprammonium solution by dialysis, and it is this substance which has the property of dissolving cellulose. It is found that when all the cupric hydroxide in a cuprammonium solution is in the colloidal state, approximately two parts of cellulose can be dissolved by each part of cupric hydroxide in solution. These colloidal solutions can be prepared in two ways:—(A). By treating solutions of copper salts with ammonia and caustic alkalis, the solutions being of such concentrations that the cuprammonium solution contains no more than 15 grms. of cupric oxide per litre. (B). By the joint action of air and ammonia on metallic copper in the cold and subsequent dialysis of the product. Pure cellulose is dissolved in liquor A to which has been added enough of liquor B to make the mixed solutions sufficiently concentrated to dissolve the amount of cellulose required for the filament to be made.—P. F. C.

Kier for scouring fabrics open width under pressure and having lateral circulation. Soc. Anon. de Teinture et Impression de Saint-Julien. Fr. Pat. 401,690, Apr. 6, 1909.

This apparatus comprises a rectangular vat which is provided with two perforated vertical sheet iron partitions arranged near to opposite walls. Between each partition and its neighbouring wall, steam coils are disposed to maintain the temperature of the scouring liquor. The vat is placed in connection with a pump by means of pipes which are so arranged that the liquor has to circulate laterally through the fabric, the latter being plaited down inside the vat, and through the perforations in the partitions. A tubular apparatus for heating the scouring liquor without diluting it is also included in the system. The apparatus is provided with devices for removing the lid of the kier and with an arrangement for keeping the material in position during the scouring operation.—P. F. C.

Bleaching of textile materials by emulsified stearine. E. Lasbordes. First Addition, dated Mar. 25, 1909, to Fr. Pat. 399,514, Feb. 8, 1909 (this J., 1909, 979).

In the bleaching process described in the principal patent, the effective agent is the stearine which, especially when it has an acid reaction, is able of itself to produce a good white. The best result is obtained if the material is exposed to air for a time after being withdrawn from the bleaching bath.—P. F. C.

Dyeing and sizing, or dyeing and starching, in one operation, yarns or fabrics made of vegetable fibres. E. F. Kur, Bournemouth. Eng. Pat. 20,743, Oct. 2, 1908.

AN alkaline size is prepared by mixing 30 lb. of farina or other sizing material with 30 galls. of cold water and next adding not less than 2 galls. of caustic soda lye of 44° Tw., the mixture being then stirred till transparent and of a pasty consistence. Ten galls. of the alkaline sizing are mixed with a boiling solution of 9 lb. of dyestuff in 20 galls. of water. This solution may then be applied to piece goods on a padding machine and to warp yarns in the sow-box of a sizing machine.—P. F. C.

Silk: Treatment of materials containing —. T. Boettger, Hackensack, and F. Vom Eyser, Rochelle Park, N.J. U.S. Pat. 935,292, Sept. 28, 1909.

THE treatment consists in subjecting the material to the action of a hot, dilute, slightly alkaline solution of Turkey Red oil and then dyeing without previous washing.—F. M.

Loading agent or sizing ingredient [for textiles]: Production of a —. J. H. Richardson, Manchester. Eng. Pat. 493, Jan. 8, 1909.

CHINA clay is dried at 212–220° F., then very finely powdered and is finally screened.—P. F. C.

Wool: Electrical process for removing the grease and yolk from — and apparatus therefor. R. Vandatte and B. Lagye, Antwerp. Eng. Pat. 5859, March 11, 1909. SEE Fr. Pat. 399,875 of 1909; this J., 1909, 934.—T. F. B.

Textile materials: Apparatus for treating — and for mixing liquids with chemicals, dyeing materials, oils, and the like. R. Diederichs, Cologne, Germany. Eng. Pat. 22,738, Oct. 26, 1908. Addition to Eng. Pat. 8821, April 22, 1908.

SEE Addition of Oct. 26, 1908, to Fr. Pat. 390,105 of 1908; this J., 1909, 471.—T. F. B.

Dyeing and printing [with dianthraquinonylamines]: Process of —. P. A. Newton, London. From Farbenfabr. vorm. F. Bayer und Co., Elberfeld, Germany. Eng. Pat. 24,810, Nov. 18, 1908.

SEE Ger. Pat. 208,845 of 1908; this J., 1909, 519.—T. F. B.

Dyeing with oxyanthraquinone dyestuffs. P. A. Newton, London. From Farbenfabr. vorm. F. Bayer und Co., Elberfeld, Germany. Eng. Pat. 26,460, Dec. 7, 1908.

SEE Fr. Pat. 397,659 of 1908; this J., 1909, 792.—T. F. B.

SEE Eng. Pat. 16,757 of 1907; this J., 1908, 499.—T. F. B.

VII.—ACIDS, ALKALIS, SALTS, AND NON-METALLIC ELEMENTS.

Hydrocyanic acid: Formation of — from ammonia and wood charcoal and from di- and trimethylamine. G. A. Voerkelius. Chem.-Zeit., 1909, 33, 1025–1026, 1078–1081, 1090–1092.

IN Buch's process (see Eng. Pat. 7171 of 1895; this J., 1896, 114) for the utilisation of the nitrogen contained in the vinasse from beetroot molasses, the latter is first subjected to destructive distillation at about 640° C., and the distillation gases, which contain steam, carbon dioxide and monoxide, hydrogen, methane, nitrogen, ammonia, and methylamines, are heated to 800°–1000° C. in a superheater. The resulting gaseous mixture contains about 7 per cent. by vol. of hydrocyanic acid, 7 of ammonia, 8 of methane, 12 of hydrogen, 18 of carbon monoxide, 24 of carbon dioxide, and 24 of nitrogen. In order to gain an insight into the reactions taking place in the superheater, the author has studied the behaviour of ammonia in presence of wood charcoal at temperatures between 700° and 1000° C., and the effect of heating di- and trimethylamine to temperatures of from 600° to 1000° C. It was found that at temperatures above 700° C. when a mixture of ammonia and hydrogen is led over wood charcoal, the gaseous mixture produced contains hydrocyanic acid, ammonia, nitrogen, and hydrogen, but no methane. The ratio of ammonia to hydrocyanic acid varies. The yield of hydrocyanic acid and the proportion of undecomposed ammonia both rise with increasing dilution of the ammonia and with increase of the velocity with which it is passed over the charcoal; dilution with coal gas is better than dilution with hydrogen in regard to yield of hydrocyanic acid. The best yield of hydrocyanic acid is obtained at about 1000° C. The activity of the charcoal gradually decreases. The experiments as to the effect of heat on tri- and di-methylamine, showed that at 800°–1000° C. the former is decomposed almost quantitatively into hydrocyanic acid and methane; below 800° C. the formation of hydrocyanic acid is less, and it ceases altogether at 600° C., at which temperature trimethylamine probably forms tetramethylhydrazine, according to the equation: $2N(CH_3)_3 - H_2 = (CH_3)_2N.N(CH_3)_2 + 2CH_4$. Dimethylamine decomposes quantitatively into hydrocyanic acid, methane, and hydrogen at 820°–1120° C., but when mixed with more than 50 per cent. of hydrogen, a portion also decomposes in accordance with the equation: $NH(CH_3)_2 + 2H_2 = NH_3 + 2CH_4$. The amount decomposed in this manner increases with the proportion of hydrogen present, until with 97 per cent. of hydrogen, hydrocyanic acid is no longer produced. The results of the investigation show that in order to obtain the maximum yield of hydrocyanic

acid in Bueh's process, the destructive distillation of the vinasse should be conducted so as to yield as much trimethylamine as possible: the hot gases should be removed from the superheater as quickly as possible; and the filling material of the superheater should consist of glazed stone or stone coated with carbon, in order to diminish the catalytic decomposition of the hydrocyanic acid. (See also this J., 1896, 449, 543; 1897, 440.)—A. S.

Electrolysis in the alkali and bleaching powder industry. B. Lepsius. Ber., 1909, 42, 2892—2916.

THOUGH the groundwork of the electrolytic decomposition of common salt was laid by Davy and by Faraday, its application on the industrial scale was not practicable till the development of the dynamo made cheap electric energy possible. The earliest attempts were made at the Griesheim works near Frankfurt; and after many failures Stroof and the Brothers Lang succeeded there in working out a practicable process. The cells were vertical, the cathodes of iron, and the anodes of carbon. The anode cells, within the cathode cells, were made of cement, salt, and hydrochloric acid, and became during use very porous through the dissolution of the finely-divided salt they contained. They were furnished with lids, through which passed tubes to carry off the chlorine. The cathode cells, 6 to 12 in an iron trough, separated by iron partitions, were provided with pipes at the bottom to run off the alkaline solution, and with tubes to carry away the hydrogen to gas-holders or compression plant. As the electrolysis proceeded, the sodium hydroxide formed shared more and more in the current, so that not only was there considerable waste of energy, but the anodic oxygen destroyed the carbon anodes, and the carbon dioxide formed diluted the chlorine, and reacted on the lime in the bleach chambers. Accordingly, anodes of magnetic oxide of iron were substituted, made by casting ferric oxide fused at the temperature of the electric arc. The oxygen now, at the bath-temperature (70° – 80° C.) formed chlorate, which crystallised out and was from time to time removed. When the alkalinity of the cathode liquor had reached the desired amount, the current was stopped, the liquor run off and evaporated, whilst fresh chloride solution was run into the cathode cells. When the concentration of the liquor reached 50 per cent., practically all the undecomposed salt separated, and was returned to the process. The Griesheim Company worked at first with 400 h.p.; in 1892 this was doubled, and soon after another work of 2000 h.p. was erected. They also erected works at Bitterfeld in Saxony (where the local lignite furnished a cheap source of power) of 3500 h.p., at Lamotte in France, and at Flix near Barcelona, where the Elbro furnished the power. The Badische Anilin- und Soda-Fabrik, the Allgemeine Elektrizitäts-Ges., and others, also erected plants to work the Griesheim process, which to-day employs about 33,000 h.p., corresponding to a yearly output of about 50,000 tons of caustic soda and 120,000 tons of bleaching powder. The process of Castner, Kellner, and Solvay began on an industrial scale in 1897. In the Castner process, the bath is divided into three by two partitions which dip into a layer of mercury on the bottom. The outer sections contain salt solution and carbon anodes, and are provided with tubes to carry off the chlorine; the middle section contains water and iron cathodes. Mechanism tilts the bath at regular intervals, so that the mercury occupies the bottom of two sections, and each half of it is alternately in the anode- and the cathode-cell. The sodium produced in the anode-cell, where the mercury is cathode, amalgamates with the mercury, and when this becomes anode in the cathode-cell the sodium is converted into hydroxide, with evolution of hydrogen at the cathode. To avoid the possible oxidation of the mercury through water-decomposition in the middle cell, due to lack of sodium ions caused by recombination of sodium and chlorine in the anode cell, which always occurs to some extent, Kellner connects the iron cathode directly with the mercury by an outside wire, so that this cell works independently of the main current. This process, or the Solvay process, in which the cell is fixed, but a constant stream of mercury passes through it, is worked in Germany at Osternienburg (1500 h.p.) and at Gersthof; in England at Oldbury and Runcorn [and Wallsend]; in Belgium at Jemappes; in Russia at Liubimow; in Austria at Golling;

in Bosnia, and at Niagara Falls. The process has the advantages of working without diaphragms, of yielding a very pure product, and of attaining a high concentration in the alkaline liquor, so that the cost of evaporation is reduced; but it needs a higher E.M.F. than the other process (4.3 volts against 3.5), presents greater technical difficulties in the working of the apparatus, and involves considerable outlay for mercury. It also requires more ground-space than the vertical cell process. The third type of process is the Austrian "bell-process," worked at Aussig, and also at Greppin and Stassfurt in Germany. Here the horizontal carbon anode, pierced with holes for the escape of chlorine, is placed in a non-conducting bell-jar, outside of which is the iron cathode. Through the neck of the jar pass tubes, for the exit of chlorine and the supply of electrolyte. The greater density of the alkali solution keeps it separate from the anode-liquid, and a slow stream of fresh electrolyte continually enters the bell, whilst an overflow of alkali-solution leaves the outer circumference of the cell. This method also needs high E.M.F., as the electrodes are so far apart, and requires considerable ground-space; but it has the advantages of avoiding diaphragms and movable apparatus.

In estimating the influence of electrolytic processes on the industry, it is to be remembered that the ammonia-soda process, which from the point of view of the production of soda presents many advantages over the Leblanc process, was not able to supplant that process entirely; the old process was still needed to supply the world's chlorine, and the sodium sulphate produced at the same time was used directly in glass-making. None of the proposals from time to time made to recover the chlorine in the ammonia-soda process have proved successful, but the electrolytic production of chlorine at once affected the Leblanc industry, which has steadily declined since, and is still declining. The early electrolytic processes worked with potassium chloride, and the world's production of potassium hydroxide (chiefly used in soapmaking) is now nearly all the result of electrolysis. Electrolytic chlorine is by no means all used in the manufacture of bleach: large quantities are used in making organic derivatives—chloroform, chloral, carbon tetrachloride, chloroacetic acid, chloro- and dichlorobenzene, etc., and liquid chlorine itself is largely sold, not only in iron cylinders, but even in large tank wagons. Moreover, the Griesheim process affords potassium chlorate, the yield of which can be greatly increased by appropriately altering the conditions. The other product of electrolysis is hydrogen: this was for long allowed to go to waste, but is now to a large extent collected and compressed, for use in autogenous soldering and welding, and for dirigible balloons. Electric energy is also largely used, apart from the alkali industry, in the production of bromine, iodine and iodoform, phosphorus, potassium chromate and permanganate, calcium carbide, sodium, calcium, magnesium, aluminium, and so forth.—J. T. D.

Alkali [sodium] nitrates and nitrites; Formation and decomposition of mixed crystals of —. G. Bruni and D. Meneghini. Z. anorg. Chem., 1909, 64, 193—199.

THE cooling and freezing-point curves for fused mixtures of sodium nitrate and nitrite have been studied, and show the formation of two series of mixed crystals of these salts, containing 0—29.5 and 35—100 per cent. of sodium nitrate respectively. It has been found, by comparing the heats of solution of mixtures prepared by fusion with those of corresponding mechanical mixtures of the salts, that the mixed crystals are almost completely broken up into their components on cooling, unless this be very rapidly effected. The presence of moisture increases the instability of the mixed crystal.—F. SODN.

Sodium sulphite; Detection of — in the presence of sodium sulphate and sodium thiosulphate. F. E. Weston. Chem. News, 1909, 100, 176.

IF to a solution of a sulphite there be added iodine in insufficient quantity to convert the whole of the sulphite into sulphate, the hydriodic acid produced reacts with the residual sulphite and sulphur dioxide is liberated—

The sulphur dioxide may be detected by its odour in strong solutions, or in weak solutions by the addition, drop by drop, of dilute potassium bichromate solution, which will be immediately reduced to a basic chromium salt and become pale green. The best method of applying the test is to add *N*/10 iodine solution to a 5 per cent. solution of the salt under examination. If decolorisation takes place the presence of a sulphite or thiosulphate or of both is indicated, whilst if the solution, after the addition of a faint trace of iodine in excess, is acid, it is probable that a sulphite is present. Another portion of the original solution is now treated with half the quantity of iodine used in the first test, and the solution examined for sulphur dioxide as described above. If no green coloration is obtained in the bichromate test a thiosulphate is present. Sulphates may be detected with barium chloride in the usual way, and the presence of a sulphite does not interfere with the confirmatory tests for thiosulphates.—C. A. M.

Calcium chloride: Solutions of lime and silica in fused —.
K. Arndt and W. Löwenstein. Z. Elektrochem., 1909, 15, 784—790.

At temperatures from 850° to 950° C., a saturated solution of lime in calcium chloride contains 13.8 per cent. of lime, or 100 grms. of calcium chloride dissolve 16.2 grms. of lime. Saturated solutions of silica in calcium chloride contain at 800°, 850°, 900°, and 950° C. respectively 2.5, 3.8, 5.4, and 7.6 per cent. of silica. The silica, however, with the oxygen of the air, decomposes the calcium chloride, so that whether silica alone, or a mixture of silica and lime, or calcium metasilicate be added to the fused calcium chloride, calcium orthosilicate, Ca_2SiO_4 , is ultimately formed. The specific electrical conductivity of fused calcium chloride at the four temperatures above mentioned is 2.40, 2.27, 2.40, 2.51; the conductivity is lowered by dissolved lime, still more by equivalent quantities of calcium orthosilicate. The density of the fused chloride at 800°, 850°, and 900° C. is 2.048, 2.026, and 2.002 respectively; it is increased by 0.009 for each 1 per cent. of lime, by 0.012 for each 1 per cent. of calcium orthosilicate, and by 0.036 for each 1 per cent. of silica dissolved.—J. T. D.

Alumina with silica, lime, and magnesia: Binary systems of —. E. S. Shepherd, G. A. Rankin, and F. E. Wright. Amer. J. Science, 1909, 28, 293—333.

IN addition to experiments with the lime-silica series of minerals (this J., 1907, 95), an investigation has now been made of the alumina-silica, alumina-lime and alumina-magnesia series. In the alumina-silica series only one compound, $\text{Al}_2\text{O}_3 \cdot \text{SiO}_2$, was found to be stable in contact with the melt, the optical properties agreeing with those of the mineral sillimanite. The two other minerals, cyanite and andalusite, which have the same composition, slowly change into sillimanite at temperatures above 1300° C. There are four definite compounds of lime and alumina, $5\text{CaO} \cdot 3\text{Al}_2\text{O}_3$, m.pt. 1387° C.; $\text{CaO} \cdot \text{Al}_2\text{O}_3$, m.pt. 1587° C.; and two with no definite melting point, $3\text{CaO} \cdot \text{Al}_2\text{O}_3$ and $3\text{CaO} \cdot 5\text{Al}_2\text{O}_3$, but which are completely melted at 1550° and 1725° C. respectively. It is considered probable that only the compound, $3\text{CaO} \cdot \text{Al}_2\text{O}_3$, occurs in Portland cement. There is only one compound of magnesia and alumina, $\text{MgO} \cdot \text{Al}_2\text{O}_3$, similar to the lime-alumina compound. The temperature range of the lime-magnesia system is too high for satisfactory investigation, but it is considered to be an eutectic series with no compounds and little if any solid solution. A detailed description is given of the optical character of the various products, together with a number of tables and curves.—F. R.

Aluminium hydroxide: Solubility of — in aluminium sulphate solutions, and artificial preparation of "aluman."
R. Kremann and K. Hüttinger. Jahrb. d. K. K. Geolog. Reichsanstalt, 1909, 58, 637—658. Chem. Zentr., 1909, 2, 1200—1201.

The authors have determined the solubility of freshly-precipitated aluminium hydroxide in solutions of aluminium sulphate at different concentrations at 20°, 40°, and 60° C.

respectively. The solubility-curves at the different temperatures are of similar form, each consisting of three distinct portions (*ab*, *bc*, *cd*). Along the first portion (*ab*) with rising concentration of aluminium sulphate, the solubility of aluminium hydroxide increases rapidly; along the second portion (*bc*) of the curve, the solubility increases more slowly to a maximum at *c*, corresponding to a concentration of 32 per cent. of aluminium sulphate at 20° C., 28 per cent. at 40° C., and 38 per cent. at 60° C. Along the final portion (*cd*) of the curve, with further increase of the concentration of aluminium sulphate, the solubility of the aluminium hydroxide diminishes. The solid phases corresponding to the different portions of the curve are aluminium sulphate, $\text{Al}_2(\text{SO}_4)_3 \cdot 16\text{H}_2\text{O}$, for the portion *cd*; "aluman," $\text{Al}_2\text{O}_3 \cdot 2\text{SO}_3 \cdot 12\text{H}_2\text{O}$, for the middle portion, *bc*, and probably a still more basic compound for the portion, *ab*.—A. S.

Lead silicates. S. Hilpert and P. Weiler. Ber., 1909, 42, 2969—2977.

THERMAL investigation of mixtures of lead oxide and silica melted together in various proportions was undertaken. The difficulties were considerable, in consequence of the low heat-conducting power of the melts. The existence of a eutectic was demonstrated, containing 24 mols. of silica to 76 mols. of lead oxide, and it was shown that a metasilicate, but no orthosilicate, exists. In all probability another silicate, richer in silica than the metasilicate, also exists. Crystallised metasilicate has a sp. gr. of 6.36, the amorphous form a sp. gr. of 5.93. The refractive indices of the glasses formed on cooling mixtures rich in lead are very high; that of the mixture corresponding in composition to the orthosilicate is 2.07. The colour of this glass is dark-yellow; as the proportion of silica in the mixtures increases, their colour becomes lighter. These glasses are not suitable for optical uses, however, as their polished surfaces are not permanent. All the mixtures richer in lead than the metasilicate are easily decomposed by mineral acids or acetic acid; as the proportion of silica increases, they are more difficult to decompose. They are all very sensitive towards reducing gases; even at 240° C. hydrogen reduces them to metallic lead with considerable speed.—J. T. D.

Silver tetrachloroplatinate: Decomposition of —, by water, and preparation of fulminating platinum. J. Jacobsen. Comptes rend., 1909, 149, 574—577.

HEXACHLOROPLATINIC acid was prepared by passing chlorine through concentrated hydrochloric acid containing platinum black in suspension, and this was treated with silver nitrate in the cold. The silver hexachloroplatinate so formed was decomposed by hot water on the water-bath, and the tetrachloroplatinic acid obtained, treated again with silver nitrate. The silver salt formed was then decomposed by boiling with water for some hours.

The yield of dichloroplatinic acid was 80—90 per cent. of the theoretical. The solution, treated with excess of ammonia, gives a precipitate which, both when suspended in the solution, and when washed and dried, strongly resembles ferric hydroxide in appearance. When heated, it first darkens, then detonates with great violence, producing platinum black, nitrogen, oxygen, and water vapour. Its composition corresponds with the formula, $(\text{OH})_2\text{Pt}(\text{NH}_3)\text{Pt}(\text{OH})_2$. A substance similar in formula and in characters is obtained if pyridine be substituted for ammonia.—J. T. D.

Platinum trioxide. L. Wöhler and F. Martin. Ber., 1909, 42, 3326—3333.

HYDRATED platinum dioxide was dissolved in 2*N*-solution of potassium hydroxide, and the solution electrolysed at a temperature of 0° C. The anode became covered with a brilliant golden-yellow film, which gradually sealed off and floated in the liquid. This substance, collected and washed with ice-cold water, gave on analysis figures corresponding with the formula, $3\text{PtO}_4 \cdot \text{K}_2\text{O}$. The alkali could not be washed out with water, but could be easily

neutralised by weak acids, even by acetic acid. The moist trioxide so obtained kept the form of the original substance, but became red-brown. It began to lose oxygen, rapidly at first, but at a diminishing rate, so that after three weeks it contained 16.5 per cent. ($\text{PtO}_3 = 19.77$, $\text{PtO}_2 = 14.1$ per cent.) and probably consisted then of a solid solution of the trioxide in the hydrated dioxide. Weak sulphuric and nitric acids hardly affect platinum trioxide; 2N-hydrochloric acid very slowly acts on it, concentrated acid very rapidly, with evolution of chlorine; most reducing agents reduce it to platinum black. Gentle warming converts it sharply into hydrated dioxide, which is in turn decomposed at a higher temperature. It liberates iodine from potassium iodide, but is very stable towards alcohol, acetic acid, and many other oxidisable organic substances. Hydrogen peroxide removes from the alkaline product of electrolysis some of its alkali, but there is no evolution of oxygen. Many observations of former authors on the behaviour of platinum are shown to be due to the formation of this new oxide.—J. T. D.

Titanium tetrachloride; *Reduction of —, by hydrogen*. H. Goerges and A. Stähler. Ber., 1909, 42, 3200—3218.

THE reaction, $2\text{TiCl}_4 + \text{H}_2 = 2\text{TiCl}_3 + 2\text{HCl}$, goes on with much greater speed as the temperature is raised; at 1200°C . it is almost complete; it can be completed at lower temperatures (900° — 1000°) if the trichloride is withdrawn by cooling. Accordingly, the authors have prepared trichloride in quantity by passing a mixture of tetrachloride vapour and hydrogen into the annular space between an inner quartz tube, heated by a platinum resistance inside it, and an outer glass tube kept cool. The hydrochloric acid formed, and any undecomposed tetrachloride are condensed in water at the far end of the apparatus, whilst the trichloride is condensed on the walls of the glass tube. It is a fine red-violet powder, rapidly decomposing in damp air. It tends even at the ordinary temperature to decompose according to the equation, $2\text{TiCl}_3 = \text{TiCl}_4 + \text{TiCl}_2$; and when heated, according to Friedel and Gherin's directions, in a stream of hydrogen, it yields a black powder consisting of titanium dichloride. The properties of this depend notably on the temperature of its preparation; some specimens are spontaneously inflammable, others not. Solutions of titanium dichloride gradually turn violet on boiling in the air, becoming converted into compounds of trivalent titanium. Nitric acid renders them first violet then colourless (trivalent and quadrivalent titanium). Titanium tetrachloride turns them violet ($\text{TiCl}_4 + \text{TiCl}_3 = 2\text{TiCl}_3$). Ammonium hydroxide, carbonate, or sulphide produces a black-brown precipitate, which presently gives off hydrogen in abundance. When titanium dichloride, produced at a high temperature, is dissolved in hydrochloric acid, there is often a distinct evolution of hydrogen, suggesting that the chloride has been in part reduced to metal.—J. T. D.

Nitrogen and hydrogen with metals; *New compounds of —*. [Tricalciumamide.] F. W. Dufert and R. Miklausz. Monats. Chem., 1909, 30, 649—654.

PURE calcium nitride absorbs hydrogen at about 700°C ., forming an addition compound which is probably tricalciumamide, $\text{Ca}_3(\text{NH}_2)_2$. This substance is remarkably sensitive to light, changing from yellow to dark grey, but it regains its original colour when heated in a current of nitrogen; it is decomposed by water with the liberation of ammonia and hydrogen. Magnesium nitride forms no such addition compound, but lithium nitride absorbs hydrogen readily on heating, giving a product which appears to be analogous with the calcium compound and undergoes a corresponding change of colour, from white to red.—F. SODN.

Rare gases [argon, etc.]; *Apparatus for the preparation of — from gaseous mixtures, using a nitrogen [high-tension] arc*. F. Henrich. Z. Elektrochem., 1909, 15, 749—751.

THE process is intended for the separation of "noble" gases from the nitrogen and methane accompanying them in gaseous mixtures obtained from hot springs, etc. The gases are mixed with oxygen and subjected to a high-

tension electric arc. The apparatus consists of a vertical tube, about 30 cm. long and 3.5 cm. in diameter, which is provided near the apex with platinum terminals connected with a large induction coil. This tube is in communication at the top with a reservoir containing a 5 per cent. solution of sodium hydroxide, which during the process is allowed to flow down the inner wall of the tube (previously cleaned with nitric acid), so as to form a mantle around the arc flame, thus absorbing the oxides of nitrogen produced and cooling the tube; the alkali forms a seal in the lower part of the tube, and the excess flows into a levelling tube and thence to another vessel, from which it is returned periodically to the reservoir. The whole apparatus, which is controlled by a series of taps at appropriate points, is first filled with the alkali, and the gas, mixed with twice its volume of oxygen, is admitted to the tube, the pressure being arranged slightly above the normal; by means of an alternating current at 110 volts and 4 ampères, a steady yellow nitrogen arc is then obtained, and more gas is let in from time to time, as absorption proceeds, without interrupting the process; when the yellow colour has disappeared from the flame, a current from about 4 accumulators is made to replace the alternating current, and a disruptive discharge is continued for some time; finally, the gas is withdrawn from the apparatus and freed from the excess of oxygen in the usual way.—F. SODN.

PATENTS.

Sodium and other chlorides; *Electrolytic decomposition of — in the manufacture of caustic soda and other useful products*. R. J. Lévy, Twickenham. Eng. Pat. 20,787, Oct. 2, 1908.

THE chlorine resulting from the electrolytic decomposition is caused to react with oxygen compounds of metals, for which chlorine has a greater affinity than oxygen, as, e.g., by passing it in a dry condition over heated quicklime, whereby, it is stated, there is produced a metallic chloride and oxygen, or a gaseous mixture containing oxygen. The process may also be applied to the electrolytic decomposition of calcium chloride for the production of metallic calcium, the liberated chlorine being converted into calcium chloride, which is again utilised in the process.—B. N.

Retort furnaces for the manufacture of gas [carbon dioxide, coal gas, etc.], and for other purposes. T. M. Thom. Cheshunt, Herts., and H. Pryor, Safron Walden, Essex. Eng. Pat. 24,332, Nov. 12, 1908.

THE patent relates to an apparatus for the manufacture of lime, carbonic acid gas, illuminating gas, etc., in which vertical retorts are arranged, in an enclosed space, around a central combustion chamber provided with lateral openings which communicate with the retort space. For convenience in discharging, the lower end of each retort is curved outwards, the upper end being provided with an outlet pipe (fitted with a stop valve) leading to a circular gas main situated above the retort chamber. In the manufacture of carbonic acid gas from limestone, suitable provision is made for the passage of superheated steam through the retorts, in order to facilitate the escape of the gas.—W. E. F. P.

Limekiln. R. Buder, Gray Summit, Miss. U.S. Pat. 931,180, Aug. 17, 1909.

THE kiln, which is designed to secure regular burning of the material, comprises a body, preferably of square section, and furnaces opening into it on opposite sides.

At the side of each furnace and independent of it, horizontal channels lead into the kiln at opposite corners, in a tangential direction, that is, parallel to the adjacent side. Air is forced through these channels, in order to produce a whirling draught in the lower portion of the kiln, and conduce to uniformity of temperature by preventing the gases following a restricted path through the material. By means of a blower, which supplies also the tangential channels, an upward suction is maintained through the furnaces and ash-pits, and gases generated by fuel which has dropped into the ash-pit are thus utilised.—F. SOUX.

Lime; Process of purifying and reconditioning spent and waste — J. G. Jones. Fr. Pat. 401,803, April 7, 1909.

SPENT or waste lime is first submitted to a mechanical purification, preferably by centrifugal means, and then the semi-liquid material is filtered by means of a press, in order to form the lime into a dense solid cake. The cakes are dried and crushed, preferably to pass a 25 mm. screen, and the carbon dioxide is expelled by calcination in a rotary kiln. The kiln gases are used for heating the air required for drying, or are themselves employed for this purpose.—F. SOUX.

Ammonium salts and iron oxide from ferrous liquors; Manufacture of — F. J. R. Carulla, Derby. Eng. Pat. 27,302, Dec. 16, 1908.

IN the manufacture of ammonium salts by the addition of ammonia to ferrous liquors (ferrous chloride or sulphate), the necessary dilution of the ferrous liquor before precipitation, is effected with the weak solution of ammonium salt produced by washing a previous batch of iron oxide. The salt contained in this wash water is thus utilised, without the expense of evaporating or distilling it, or allowing it to run to waste, as at present done.—F. SOUX.

Ammonia from aluminium nitride; Process for producing — O. Serpek, Niedermorschweiler, Germany. Eng. Pat. 15,997, July 8, 1909. Under Int. Conv., July 15, 1908.

ALUMINIUM nitride is completely decomposed by treatment with a mixture of an alkali aluminate and water, which reacts like a solution of alkali. 100 parts of nitride, 120 of potassium aluminato, and 200 of water are suitable proportions, and, in carrying out the process, it is best to operate so that the nitride is first decomposed with an alkaline lye and then boiled; ammonia is given off and a solution of aluminate formed which is used for treating a fresh portion of nitride, the heating being done preferably under pressure. All the nitrogen is recovered as ammonia in 1–1½ hours.—F. SOUX.

Sodium peroxide; Method of treating — D. E. Parker, Niagara Falls, N.Y. U.S. Pat. 935,542, Sept. 28, 1909.

SODIUM peroxide, or other alkali peroxide, is purified by melting in an open vessel, by contact with electrodes and a resistance material through which a current is passed. Such a temperature is maintained, that carbon dioxide is liberated without any decomposition of the peroxide itself taking place.—F. SOUX.

Lithium compounds; Manufacture of pure — E. Zell, Gottenborg, Sweden, Assignor to General Electric Co., New York. U.S. Pat. 935,880, Oct. 5, 1909.

A LITHIUM ore is heated in the presence of carbon in an atmosphere of acetylene to form volatile lithium hydrogen carbide which is decomposed by water into lithium hydroxide and acetylene, the latter being collected and used for the treatment of fresh quantities of lithium ore.—W. C. H.

Hydrogen sulphide generator. E. L. Ross, Everett, Wash. U.S. Pat. 936,168, Oct. 5, 1909.

THE apparatus consists of a receptacle for a liquid, open at the top, and on the bottom of which is a support with arms. A bell-jar rests on the arms within the receptacle, and is prevented from moving upwards by wires, which hold the shoulders of the bell-jar, and are fastened to the

top of the receptacle. A perforated basket is arranged inside the bell-jar, and rests solely on the upper face of the support, so that the bottom of the basket is above the lower edge of the bell-jar.—W. C. H.

Lead hydride; Use of magnesium for the preparation of metallic hydrides, particularly — M. M. J. Bouffort. Fr. Pat. 401,473, April 1, 1909.

LEAD hydride is prepared by immersing magnesium in a solution of lead acetate or basic lead acetate, in the cold, when the metal becomes covered with a thick spongy layer which possesses all the properties of the hydride prepared electrolytically, and can be used for similar purposes, such as the manufacture of accumulator plates or as a source of nascent hydrogen.—F. SOUX.

Hydrosulphites; Process for the preparation of anhydrous — Chem. Fabr. Von Heyden Akt.-Ges. Ger. Pat. 213,586, July 25, 1908.

IT has been found that dry hydrosulphites containing water of crystallisation are so resistant to decomposition, compared with the moist salts, that they can be completely dehydrated by heating at 80°–110° C., preferably at about 100° C., in a vacuum or in a current of inert gas, provided that they are maintained in a "dust-dry" condition during the process.—A. S.

Hypochlorite solutions; Process for the electrolytic production of — E. A. F. Düring. Ger. Pat. 213,588, Nov. 12, 1908.

THE essential feature of the process consists in adding continuously water or a salt solution to the alkaline cathode liquid and a concentrated solution of salt to the anode liquid, which itself also consists of a concentrated solution of salt, so that the alkali and chlorine are forced to travel from the cathode and anode respectively to a middle space or layer, from which the alkali hypochlorite solution, which must be kept faintly alkaline, is continuously removed. The process may be worked with or without diaphragms, and chlorine may be removed from the anode and pumped into the middle layer in the former case; when working without diaphragms, care must be taken that the hypochlorite solution is withdrawn continuously without disturbing the three separate layers of liquid, viz., the anode, cathode, and intermediate solutions. It is stated that with suitable precautions, and with carbon anodes and iron or carbon cathodes, an almost theoretical current-yield can be attained, with production of a hypochlorite solution containing up to about 80 grms. of available chlorine per litre.—A. S.

Alkali hypochlorite solutions; Process for the electrolytic preparation of stable — Elektrizitäts-Akt.-Ges. vorm. Schueckert und Co. Ger. Pat. 213,590, Nov. 17, 1908.

IT is the practice to add caustic alkali to electrolytically prepared alkali hypochlorite solutions, in order to improve their stability. According to the present patent, a caustic alkali solution is added continuously to the electrolyte, in the preparation of the hypochlorite, in quantity sufficient to maintain a faintly acid or neutral reaction. It is claimed that in this way, not only is less alkali required, but as the electrolyte at no part of the process contains any considerable quantity of free hypochlorous acid, the yield of hypochlorite is increased, and solutions of a higher concentration of available chlorine are obtained.—A. S.

Hydrogen; Process of producing — G. M. Clark, London. From Dellwik-Fleischer Wassergas-Ges., Frankfurt on Main, Germany. Eng. Pats. 21,479, Oct. 10, 1908, and 7849, April 1, 1909.

SEE Fr. Pat. 395,132 of 1908; this J., 1909, 310. In Eng. Pat. 7849 of 1909, the use of iron pyrites, roasted to expel all sulphur and volatile metals, is claimed.—T. F. B.

Hydrogen; Preparation of pure — G. W. Johnson, London. From Chem. Fabr. Griesheim-Elektron, Frankfurt, Germany. Eng. Pat. 3188, Feb. 9, 1909.

ALUMINIUM in a divided form such as filings, dust, chips, or factory waste, is mixed with a small quantity of a

compound of a metal such as mercury, platinum, or gold, which is electro-negative to aluminium, and with a small quantity of an alkali or acid, or a borate, phosphate or other soluble substance. This mixture can be stored in the dry condition, and when added gradually to water it yields 1.2 cb. m. of hydrogen per kilo. The alkali, etc., serves to generate sufficient hydrogen to reduce the mercury or other compound, which then forms an electro-chemical couple with aluminium and decomposes water until the aluminium is used up. A suitable mixture consists of 1 part of mercuric oxide, 1 part of powdered caustic soda, and 98 parts of aluminium.—A. T. L.

Air; Liquefaction of — and separation into its constituents. Soc. L'Air Liquide (Soc. Anon. pour l'Etude et l'Exploit. des procédés G. Claude). Fr. Pat. 401,496, July 24, 1908.

The invention relates to a means for accomplishing the liquefaction of air and the separation of oxygen and nitrogen in a single cycle of operations. Compressed air, after passing through heat interchangers, cooled by the escaping

reduced to a minimum by providing a removable bottom to the vertical cylindrical resistance furnace and arranging the calorimeter immediately below it. The crucible was suspended by a fine platinum wire, and when required the furnace bottom was swung aside and a heavy charge of electricity passed through the supporting wire, which fused and permitted the crucible to fall directly into the water. Preliminary determinations made with an empty crucible, counteracted the small errors due to the splashing of some of the water, etc. The calorimeter was completely enclosed by a water-jacket and a temperature rise of as much as 23° C. was successfully employed, the wide range increasing the accuracy of reading the thermoelements which were employed for all temperature determinations. It is claimed that a final accuracy of better than 0.5 per cent. is obtained. Specific heats of silicates show a considerable increase with rise of temperature up to 700° C., followed by a tendency to diminish at higher temperatures. The values of the true specific heats of the substances experimented with are given in the following table:—

Temp. °C.	Platinum.	Wollastonite.	Pseudo-wollastonite.	Orthoclase.	Diopside.	Orthoclase glass.	Soft glass.

—F. R.

gases, is allowed to expand, doing external work. From the expansion engine, the air is sent to a group of closed tubes, immersed in liquid oxygen, in which it accumulates until liquefied by its own pressure, preferably collecting as a more volatile and a less volatile fraction (this J., 1905, 969), which are used as reflux liquids in the upper and lower portions respectively of a rectifying column surmounting the liquid oxygen boiler. The gaseous oxygen from the lower part of this column is led away through a heat interchanger and thence to be utilised, and the more or less pure and extremely cold nitrogen, escaping from the top of the column, is made to pass around the tubes in the liquefier, before helping to cool the entering compressed air in another heat interchanger. The whole of the liquid required in the cycle is thus produced in the system itself.

—F. SODN.

Oxygen; Process for the production of —, e.g., for use in internal combustion engines for submarines and torpedoes. P. Wienand. Ger. Pat. 213,686, Aug. 4, 1906.

A MIXTURE of an alkali peroxide and an alkali perchlorate, which melts at a much lower temperature than either of its components, is melted and heated to a temperature below that at which oxygen is evolved. It is then transferred to the place at which it is desired to produce the oxygen and is heated more strongly in presence of water; or the oxygen of the perchlorate and of the peroxide respectively may be liberated in two stages, first by heating strongly and then by treatment with water. The water is preferably used in the form of a solution of alkali hydroxide of high boiling point.—A. S.

VIII.—GLASS, POTTERY, AND ENAMELS.

Silicates and platinum; Specific heats of —. W. P. White. Amer. J. Science, 1909, 28, 334—346.

THE paper describes the beginning of an investigation into the thermal properties of silicates. The method employed for determining the specific heats up to 1500° C., was to drop the crucible containing the heated substance into a water calorimeter at room temperature. The error due to loss of heat occurring during the passage of the heated body from the furnace to the water was

Alumina; Effects of — on glass. R. L. Frank. Trans. Amer. Ceram. Soc., 1909, 11, 99—102.

MANUFACTURERS who insist on their sand being scrupulously washed, thereby lose one of the most valuable ingredients of their raw materials. The loam which is removed contains alumina, which, in quantities of 3 to 4 per cent., vastly improves the qualities of glass. It acts as a vehicle for forming combinations between silica and lime, or soda, taking the part of either acid or base. It facilitates the making of a homogeneous body, as the glass is not so susceptible to the reducing action of the fire, or to the formation of cords and strings, or production of a laminated condition. In glass made in moulds, or in a machine, alumina increases the surface tension, so that the glass will have less tendency to take the imperfections of the moulds, while it renders the glass sufficiently pliable to be forced into any desired shape. It reduces the co-efficient of expansion, and increases the tenacity, which is valuable in the manufacture of bottles. It also exerts a favourable influence in the annealing process. It has one drawback, in that it does not mix well with cullet, so that care must be taken not to have too large a proportion of cullet in the mixing.

—H. H. S.

Clay press; Can water from the — be re-used? T. Gray. Trans. Amer. Ceram. Soc., 1909, 11, 365—368.

A DISCUSSION on this question elicited varying opinions. The author stated that "a large saving could be made by re-using this water, and perhaps the bacteria thus preserved would present a simpler means for developing plasticity than by the artificial process in which tannin or straw is used." On the other hand, the re-used water gradually becomes richer in soluble salts and finally these salts may be simply re-distributed evenly through the clay. A great deal depends on the composition of the water, and of the soluble salts in the clay. If the water is a hard, limy one, it is of no use for washing clay saturated with the same impurity. Where, on the other hand, the salts in the clay consist of easily soluble chlorides and nitrates and some sulphates, there is no likelihood of the wash-water becoming saturated.—H. H. S.

Clays; Effect of preliminary heat treatment upon —.
A. V. Bleiminger. Trans. Amer. Ceram. Soc., 1909, 11, 392—406.

PLASTIC clays often crack during the drying process. Weathering overcomes this difficulty to a great extent, but the author finds that heating the clay from 200°—350° C. causes it to show a greatly decreased shrinkage on drying. If exposed to the action of water for long periods, the clay would doubtless resume its original plasticity, but in a few hours the recovery is only partial. The loss in plasticity at increasing temperatures is not abrupt but gradual. The decrease in shrinkage proceeds hand in hand with a decrease in the amount of water required to form the clay into a plastic mass, but no simple mathematical relation exists between the two factors. It does not follow that the more plastic a clay is originally, the more it is affected, as regards drying, by the heating treatment; different clays require different temperatures. With none of the heated clays did any cracking appear during drying.—H. H. S.

Marly clay as fluxing material for easily fired bodies.
E. Berdel. Sprechsaal, 1909, 42, 581—583, 595—597.

THE author has examined the fluxing effect on ceramic bodies of easily fusible clays with a relatively large content of lime (marls). As fluxes, they have the advantages that they are plastic, have a fine grain, and can be easily ground and mixed in a body. The marl used consisted of 34.8 per cent. of clay substance, 27.5 per cent. of quartz, 5.2 per cent. of feldspathic material, and 32.5 per cent. of calcium carbonate; it melted at about Seger cone 1. From mixtures of 40 parts of this, and 60 parts of various kaolins and clays, tiles were made, and fired at different temperatures, and the contractions and porosities measured. On the whole it appeared that calcareous, easily fusible clays were a useful means of bringing about sintering, at comparatively low temperatures, of stoneware and other highly plastic clays, and where a tile clay, such as the above, cannot be obtained, a potters' or brick clay can be substituted. Generally speaking the marly clay produced more effect than loam, which also tends to give a speckled surface, unsuitable for some kinds of plain ware. The best result obtained was a stoneware body composed of equal parts of Hämmerbach (Westerwald) clay and washed marly clay, which burned dense at Seger cone 1—2, retained its shape well, and had a lustrous, conchoidal fracture. The composition of the mixture in percentages was:—clay substance 43.0, quartz 36.85, feldspar 4.35, and calcium carbonate 16.25. As an extension of the use of such a low-fired body to stoneware manufacture, suitable glazes of the following formulae may be used, and fired at Seger cone 1—2. I. $0.25\text{K}_2\text{O}$, $0.25\text{Na}_2\text{O}$, 0.30CaO , 0.20BaO ; $0.4\text{Al}_2\text{O}_3$; 3.2SiO_2 , $6.5\text{B}_2\text{O}_3$. II. $0.15\text{Na}_2\text{O}$, $0.20\text{K}_2\text{O}$, 0.20CaO , 0.45PbO ; $0.28\text{Al}_2\text{O}_3$; 2.5SiO_2 , $0.3\text{B}_2\text{O}_3$. III. $0.15\text{K}_2\text{O}$, 0.20CaO , 0.65PbO ; $0.2\text{Al}_2\text{O}_3$; 1.8SiO_2 . The warm, dark yellow colour of the glazed and unglazed ware is quite suitable for many purposes, but all three glazes are suitable also for producing deep coloured glazes. The boron-free glaze III. is well adapted for matt effects, especially if the content of lime is increased, or rutile or magnesite is introduced. A suitable white engobe, similar in rational composition to the body, except that the amount of fluxing material (feldspar) is increased, is compounded of 400 parts of Zettlitz kaolin, 100 parts of feldspar, 340 parts of quartz, and 160 parts of whiting, and coloured engobes can be produced from this by the addition of the requisite colouring oxides. Almost all the earthenware underglaze colours are bright and permanent with glaze II. given above. The low temperature, Seger cone 014, of the biscuit-firing is a great advantage of the whole scheme, and the pieces become so hard on drying that simple objects can even be painted before firing.—W. C. H.

Sulphur problem [pottery]; Method of overcoming the —.
H. B. Wells. Trans. Amer. Ceram. Soc., 1909, 11, 93—98.

THE presence of sulphur in a clay may cause discoloration and distortion in burning. To overcome this, the author experimented on the commercial scale, and in ordinary

down-draught kilns, with a clay containing 1.82 per cent. of sulphur, in the form of pebbles of pyrites. The sulphide, FeS_2 , oxidises in two stages, the first atom of sulphur at 400° C., and the second at 900° C., and the principle of the method followed was to shut off heat at the first stage so that the oxidation of the sulphur could take place slowly and regularly. The kiln was brought up to the ignition point of the sulphide, when the fires were allowed to die out, the fire-boxes were closed up, and the openings in the top of the kiln were uncovered, whilst the gases were shut off from the stack entirely. The heat advanced slowly and gradually from the outer courses towards the centre. Shortly before evolution of sulphurous gases ceased, the top was closed, the damper opened to the stack, the fire started, and the burning carried out to the end in the usual manner. The result was uniform burning throughout the kiln.—H. H. S.

Porcelains of potash and soda felspar; Comparison of —.
A. S. Watts. Trans. Amer. Ceram. Soc., 1909, 11, 179—184.

IT has been said that soda spar, or albite, cannot be used for the manufacture of white ware, owing to the fact that it imparts a dull, wooden ring to the ware, whereas with the potash spar, a clear glass ring is obtained. To test this, trials were made in a body of composition 0.16KNaO ; 0.08CaO ; $1.0\text{Al}_2\text{O}_3$, 4.5SiO_2 . The bodies were made up into bell-shaped cups, and the difference in tone was very marked. Under physical tests, however, such as resistance to electric current and to sudden changes of temperatures, no difference could be observed. As soda spar is cheaper than felspar, its substitution is worth a trial where the ring of the ware is immaterial. Care must be exercised that grinding is carried to the same degree as with the potash spar, otherwise the economy obtained from its lower fusing point and its lower cost will be largely lost.—H. H. S.

Porcelains; Crystalline structure in —. A. S. Watts. Trans. Amer. Ceram. Soc., 1909, 11, 185—201.

THE author summarises his views as follows. Of all the ingredients in porcelain, the felspar is the first to act. At cone 9, a hard spar binds together the other ingredients to a conglomerate mass. As the temperature rises, the spar becomes more active, dissolving first the clay substance and then the flint particles, till at cone 10, there is evidence of crystallisation of sillimanite. At cone 13, a hard felspar is completely fluid, permitting such complete crystallisation as conditions and other ingredients will allow. A soft felspar may make a difference of two cones in the maturing temperature, an equal amount of dissolving action being obtained. The addition of another flux causes the matrix to become more active as a solvent. Whiting and marble are more powerful in this respect than plaster. Soda felspar produces the greatest change, giving the matrix a dissolving power that is remarkable. Soda-spar porcelain contains clusters of segregated bubbles, which is also a peculiarity of bodies containing fritted material. In this case, the matrix is sufficiently fluid to let bubbles move more freely, and the segregation occurs accordingly. Cornish stone acts more like a frit than a spar, though its fluxing action is not equal to that of a frit of the same composition. It is advantageous to frit spar and lime together rather than to frit spar alone. Turning to the clay ingredients of porcelain, ball clays are notably less soluble in fused spar than china clays, though ball clay porcelain displays a finer texture. Crystalline development is greater in the china clay porcelain. A bibliography is given of previous papers on this subject.

—H. H. S.

Porcelain; The coefficient of linear expansion of —.
A. S. Watts. Trans. Amer. Ceram. Soc., 1909, 11, 84—87.

A LONG straight unglazed porcelain tube was immersed in oil heated by an electric resistance coil. The expansion of the tube caused a lever to move, and was read off by means of a mirror and telescope. The average of six determinations furnished the coefficient, 0.00005357 for temperatures between 19° and 243° C.—H. H. S.

Chromium-tin pinks; A study of — R. C. Purdy and G. H. Brown. Trans. Amer. Ceram. Soc., 1909, 11, 228—261.

THE authors investigated the effect, on the pink colour, of chromium in varying amounts, introduced as the green oxide, as lead chromate, and as potassium bichromate; also, the effect of calcium in varying amounts, introduced as carbonate. Analyses of nine stains already in commercial use showed that lead oxide was present in five, and sodium and potassium oxides in four; also that, taking the equivalent of tin oxide as unity, the chromium trioxide varied from 0.0091—0.0155, the lime from 0.744—3.6, and the silica, though generally about unity, varied in extreme cases, from 0.437 to 3.33 equivalents. In the present experiments all the stains contained one equivalent each of tin oxide and silica; the stains were not melted, but merely calcined; they were not washed nor re-calcined. The same glaze was used throughout, viz.:—PbO, 0.22; CaO, 0.60; KNaO, 0.18; Al₂O₃, 0.16; SnO₂, 0.1; SiO₂, 2.1; B₂O₃, 0.475; and Cr₂O₃ varying. Of this, 0.625, CaO; 0.375, KNaO; 0.23, Al₂O₃; 0.72, SiO₂; 0.989, B₂O₃, was fritted. The authors conclude that the source of the chromium does affect the tint obtained. The group containing the trioxide showed the largest number of stains having a pink colour, similar to those found on the market. The pinks made with lead chromate were lighter than those made with the trioxide and potassium bichromate. The bichromate group showed a tendency to dark brown colours when high in chromium, and when water was added the pink was lost and the stains turned yellowish-brown, probably owing to formation of chromic acid. Only the merest trace of chromium is necessary to develop the pink colour. With the trioxide and bichromate, the limits are 0.0001 to 0.0375 equivalent, but the amount of lead chromate may be as high as 0.15. With regard to calcium, the stain can carry at least three equivalents, the fusibility being the only limiting factor. The greater the proportion of lime, up to 25 per cent., the higher the temperature the colour will bear. Decrease of lime tends to change the pink into greyish-brown. The authors deny that the composition of the glaze is more important than that of the stain. It is only necessary that the glaze should be relatively low in lead and alkalis, and high in calcium. In the discussion, fluorspar and gypsum were said to produce better reds than whiting, and boric acid was said to improve the stains, using high boric acid with high lime content, and low boric acid with low lime content.—H. H. S.

Melting points of glaze and glass silicates of the porcelain type as used in the ceramic industry; Method for determining — M. Barrett. Trans. Amer. Ceram. Soc., 1909, 11, 80—83.

THE author postulates at the outset that the materials used are in the finest state of subdivision, and that the glazes are subjected during fusion to a sufficiently prolonged heat. He finds that one equivalent of calcium oxide is equal in fluxing value to $\frac{1}{2}$ equiv. of potassium oxide (K₂O), $\frac{1}{2}$ equiv. of sodium oxide, $\frac{1}{2}$ equiv. of zinc oxide, and 1.0 equiv. of barium oxide, and he accordingly calculates all bases into their fluxing equivalents of calcium oxide (CaO). It is then found that the glaze, 10SiO₂, 1Al₂O₃, 6 $\frac{1}{2}$ RO, melts at 1200° C., and that 1 equiv. of silica neutralises $\frac{2}{3}$ equiv. RO in point of fusibility, so that 11SiO₂, Al₂O₃, 6 $\frac{1}{2}$ RO, and 9SiO₂, Al₂O₃, 6 $\frac{1}{2}$ RO, would also melt at 1200° C. Also, by deducting $\frac{1}{2}$ equiv. of RO, the melting point is raised 5° C., so that, say, 10SiO₂, Al₂O₃, 6RO, would melt at 1215° C. To elucidate the method of calculation, an example is given. Having thus found the melting point of a glaze, the correct firing temperature should be 90° C. above it, to develop the glaze properly. This method refers to glazes of the usual type. Those in which bases predominate, so that silica is used as a flux, do not conform to the method outlined.—H. H. S.

Matt glazes. F. H. Rhead. Trans. Amer. Ceram. Soc., 1909, 11, 157—174.

FIVE series of trials were made to produce a matt glaze with a broken surface, maturing at cone 1. In the first

series, the best results were obtained from the formula:—K₂O, 0.135; CaO, 0.376; ZnO, 0.082; Al₂O₃, 0.208; SiO₂, 0.958; CuO, 0.032; Fe₂O₃, 0.0026; PbO, 0.162—0.405; BaO, 0.0—0.053. The second series, made to study the effect of underglaze stains, was based on the glaze with formula:—PbO, 0.621; K₂O, 0.184; BaO, 0.195; Al₂O₃, 0.246; SiO₂, 1.28; and all the results were good. The variations in the next series, based on PbO, 0.737; K₂O, 0.120; BaO, 0.144; Al₂O₃, 0.157; SiO₂, 0.85; were only those in colours, and the results were beautifully matt with striking flaking effects. Series four was a study in double dips of glazes in the first series. A soft biscuit was used that the glazes might dry almost immediately. The lower glaze was the heaviest, being two-thirds of the total glaze thickness. In the last series, very handsome water line effects were obtained by use of a formula:—PbO, 0.492; CaO, 0.254; K₂O, 0.087; ZnO, 0.167; Al₂O₃, 0.30; SiO₂, 0.948. With regard to the separation in matt glazes, the flakes decrease in size with increase of silica, with decrease of alumina and of lime. Barium oxide is more potent than lime in producing flakes. No good matt effects were obtained without zinc oxide. Surface cracking is generally mechanical in origin, being due to the cracking of the drying glaze, healing over at the joints, or, to the thickness of the glaze. In some cases it is due to chemical causes, such as alumina making the glaze too hard, or barium carbonate giving off its carbon dioxide slowly and at a high temperature.—H. H. S.

Opalescence in highly acid glazes; A study on the production of — J. D. Whitmer. Trans. Amer. Ceram. Soc., 1909, 11, 262—295.

OPALESCENCE appears to be due to the refraction of light by particles of undissolved matter suspended in the glaze matrix. Purdy had previously laid down the rule that opalescence can be produced in a glaze by supersaturating it with silica at high oxygen ratios, at least 1:4; that 0.20 equivalent of alumina is also requisite, and that the higher the boric acid, the better the opalescent effect. The author made a series of experiments, keeping the alumina constant, varying the lime at the expense of the lead, varying the oxygen ratio from 3.0 to 6.5, and the molecular ratio of B₂O₃ to SiO₂ from 1:2.0 to 1:6.5. No good opalescence was developed, and no decided conclusions reached, but a few points were noted. The actual composition of the floating matter in the matrix seems immaterial, but it should be finely sub-divided or opacity will be produced instead of opalescence. The glaze coating should be as thick as possible. The best oxygen ratio was from 5.5 to 6.5, the best silica-borate ratio was between 3 and 4. The lime is high enough at 0.5 equivalent. The best temperature range is from cones 1 to 5. The author then turns to the subject of boric acid and crazing. To lessen crazing, it is better to increase the oxygen ratio or the firing temperature, than to alter the proportion of boric acid.

—H. H. S.

Glazes; A peculiar property of some — A. E. Mayer. Trans. Amer. Ceram. Soc., 1909, 11, 369—374.

A "ROPEY" glaze mixture is one that settles quickly to the bottom of the tub; the grains interlock, forming a very dense mass that can hardly be dug out with the fingers. The defects of such a glaze are apparent in dipping a piece of flat ware, as the glaze rolls in pools round the edge instead of being thrown off. The author found that this viscosity was accompanied by alkalinity, and the greater the alkalinity the more viscous the glaze. The remedies are both physical and chemical. In the former class are those substances which thicken the slop so that the glaze will not sink. Amongst these are syrup, milk, blood, gum, dextrin. The chemical remedies depend on the neutralisation of the alkali, which seems to be present as sodium silicate. Boric acid, weak mineral acids, acetic acid are used, but the author recommends one-half per cent. of magnesium sulphate. He states that this amount of sulphate will not give rise to "seumming."—H. H. S.

Enamels; The allowable limit of variation in —. J. B. Shaw. Trans. Amer. Ceram. Soc., 1909, 11, 103—152.

THE paper refers to enamel on sheet steel. The objects of the investigation were to find an enamel that would adhere to the steel without crazing or peeling, to find the relation between undercoat and subsequent coats, to produce an enamel that resists dilute acetic acid, contains no lead, and has a pleasing appearance. The furnace was heated to 1040°C . The time of burning of the ware was from four to ten minutes, the ground coat requiring more severe treatment than subsequent coats. The general conclusion is stated in the following formulae:—Ground coat, K_2O , 0.15—0.75; Na_2O , 0—0.6; CaO , 0.14—0.64; CuO , 0—0.06; Al_2O_3 , 0.1—0.5; SiO_2 , 1.1—1.7; B_2O_3 , 0.2—0.5; cover enamel, K_2O , 0.0—0.6; Na_2O , 0—0.65; CaO , 0.2—0.6; Al_2O_3 , 0—0.5; SiO_2 , 1.0—1.8; B_2O_3 , from 0.2 upwards. Potassium and sodium oxides may be interchanged without marked result, but potassium oxide gives a more brilliant surface. Lime is the most active component in affecting refractoriness. Enamels without any lime are too soft for practical use. Alumina increases the opacity, brilliancy and hardness; it also increases the refractoriness and viscosity. Silica renders the enamel acid-resisting and prevents crazing. Boric acid causes peeling, more so than silica, and it also affects the brilliancy of the enamel more than silica. A low proportion of boric acid produces matt enamels. Cobalt oxide increases the stability of the enamel in burning, and its toughness. It also intensifies the whiteness of the enamel. The substitution of calcium carbonate for fluorspar makes no difference in the finished product, but it renders the raw enamel more difficult to frit. Cryolite in place of felspar softens the enamel markedly and produces opacity. It also tends to crazing. The best results are given by mixing equal amounts of cryolite and felspar. Tin oxide produces opacity, but may be replaced by zinc oxide plus antimony trioxide. To produce good opacity 0.13 equivalent of tin or its substitute is required.—H. H. S.

Enamelled sheet-steel wares; Notes on the testing of —. E. Orton. Trans. Amer. Ceram. Soc., 1909, 11, 320—341.

THE author appeals for standard methods of testing enamelled ware. The Hooper solubility test is the only one which attempts to classify ware. The method is to boil the ware in 10 per cent. acetic acid solution until all the liquid has evaporated, and note whether the glaze has suffered damage. If it has not, it is again boiled with 20 per cent., or stronger, solutions of acid until the glaze has been attacked, and the enamel is classified accordingly as having resisted acid of a stated strength. Other chemical tests relate to the solubility of the enamel in water and in dilute mineral acids, and its ability to withstand acid gases. The physical tests deal with the ability of the enamel to withstand bending without cracking, and impacts without shattering. The former is determined by measuring what amount of deflection under pressure the enamel will undergo without cracking, and the latter by counting the number of blows of equal force on one spot necessary to shatter it. No correlation can be shown between the chemical resisting properties and the physical strength of enamels now on the market. In judging a ware, it must be remembered that the chemical qualities of an enamel are of different degrees of importance in different wares. For table ware, culinary ware, or chemical utensils, solubility is the worst possible fault, whereas for advertising signs or automobile tags the physical qualities are more important. Enamels for electric heating devices must be tested for conductivity. Coloured enamels are generally better than white ones for this purpose. Possibly the small amount of cobalt silicate formed in a blue enamel, makes it a better insulator than the white glazes which contain suspended oxides or salts.—H. H. S.

PATENTS.

Glass heating and drawing furnace. U. Houze, Grand Rapids, Mich. U.S. Pat. 935,789, Oct. 5, 1909.

A MELTING tank, with side openings for lading, a heating pot, and a drawing pot are arranged in series. Molten glass passes along a trough, with a spout, from the tank to the heating pot and this communicates above and below a partition with the drawing pot. The latter has a movable flat top, provided with a central opening and movable cover, and also has an opening at the side opposite to the heating pot. Above the heating pot is a dome, provided with openings to admit heat above the level of the glass in the pot. The pots are spaced apart from, and surrounded by masonry, which also encloses the dome, and the wall in front of the drawing pot and of the dome can be removed without disturbing the rest of the masonry.—W. C. H.

Glass; Electric furnace for the continuous manufacture of —. M. Sauvageon. Fr. Pat. 401,744, Aug. 7, 1908.

MELTED glass is a conductor of electricity, but it has a high resistance. If, then, a current of electricity be passed through a bath of molten glass, the resistance offered will cause heat to be generated, so that more glass-material may be melted. The furnace contains a bed filled with molten glass on which the material floats, and this bed is furnished with a channel to draw off the refined glass.—H. H. S.

China clay; Preparation of —. A. G. Salamon, London, C. J. Grace, Steyning, Sussex, and The Exploration Co., Ltd., London. Eng. Pats. 2294 and 2295, Jan. 30, 1909.

A LARGE proportion of the china clay from Cornwall and Devonshire is known as "bleaching clay," and its selling value depends largely on its freedom from colour. It is proposed to remove any colouring matter by subjecting the clay emulsion to the action of oxalic acid, either in hot or cold solution, or of sulphurous acid or one of its compounds. The oxalic acid or sulphurous acid should afterwards be washed out when the clay goes through the filter-press. This process is also applicable to "potter's clay," provided that it does not contain an undue proportion of mica containing colouring matter, in which case the stain would become visible on firing.—H. H. S.

Enamelling furnaces; Means for charging and discharging —. Wanderer Werke vorm. Winkhofer und Jaenicke, Akt.-Ges., Chemnitz, Germany. Eng. Pat. 7839, April 1, 1909. Under Int. Conv., April 3, 1908.

To prevent loss of heat, enamelling furnaces may be charged and discharged by means of trolleys running on rail tracks between the furnaces and work-shops. For this purpose a transferring or traversing carriage is used, movable on a track in front of a bank of furnaces out of which rail-tracks extend. The present invention consists in providing the carriage with a number of rail-tracks, so that immediately after running a trolley out of the furnace on to one of the tracks, another trolley can be run into the furnace off another track.—H. H. S.

Enamelling in one stage; Process of —. P. Woog and M. Delage. Fr. Pat. 401,543, July 29, 1908.

AN oxyhydrogen or acetylene flame is directed on to the spot where the enamel is required, while the finely-ground enamel is also projected on to the same spot. The process is specially adapted to such shapes and sizes of ware as cannot be introduced into a kiln.—H. H. S.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

Clays; Determination of the physical properties of —. Sokoloff. Tonind.-Zeit., 1909, 33, 1256—1260, 1286—1289, 1295—1298.

WHEREAS the chemical composition is of the greatest importance in the case of high-grade clay intended for porcelain, stoneware, and the like, it is the physical properties which determine the value of low-grade clay suitable for bricks, tiles, and common building purposes. These are, amongst others, the water-absorbing power, contraction on drying, plasticity, and burning temperature. The author determined the plasticity of different samples of clay by moulding small pyramids of definite size and shape, and measuring the time these pyramids retained their shape, when placed under gently running water. He mixed clay and quartz-sand in various definite proportions, and representing the quartz content and the life of each sample graphically, obtained unbroken curves for each specimen of clay. Each diagram contained two critical points, between which the curvature reached its maximum, these points being taken by the author to be an index of the plasticity, and to indicate the greatest amount of "thinning" material that could be added to the clay in practical use. The relative porosity was determined by burning samples of the clay, and boiling the burnt samples in distilled water until saturated, carefully wiping with filter paper, and reweighing the samples so treated in closed glass tubes. The "water-penetrability" was determined by subjecting cylindrical slabs of burnt clay to a certain head of water and measuring the rate of leakage through the plates. Regular curves were obtained for this property, also for clays with graduated admixtures of "thinning" material, and the author draws attention to the remarkable fact that the penetrability of burnt clay decreases with the repeated subjection of the same sample to water pressure. The author concludes that the most important points to be settled in connection with clays are: (1), The determination of the standard amounts of "thinning" materials of various degrees of fineness, that can be added without detriment to the plasticity; (2), the determination of the effect of different degrees, and of different duration, of burning, on the density of the burnt material; (3), the study of the effect of repeated burning on one and the same mass of material under varying conditions; (4), the exact determination of the water-penetrability of pottery and roofing-tile clays, and of other ceramic materials.—O. R.

Silica; Studies in the uses of finely-divided —. S. W. Parr, T. R. Ernest, and W. S. Williams. J. Ind. and Eng. Chem., 1909, 1, 692—694.

A DESCRIPTION is given of attempts to prepare artificial stone from the finely-divided silica which occurs in extensive deposits in Southern Illinois. (The material consists of minute, transparent particles of silica, 0.2 to 50 mm. diam., of crystalline structure, loosely cemented together by a small amount of clay; it contains 0.15 per cent. of moisture, 98 of silica, 0.2 of magnesia, and 1.21 of alumina.) When formed into bricks with lime in the proportion of 80 of silica to 20 of lime, and subjected to a steam pressure of 150 lb. per sq. in. for 10 hours, a product with a tensile strength of 278 lb. per sq. in. was obtained. To examine the effect of heat on the product, a number of bricks were heated, and test-samples withdrawn at different temperatures, and their tensile strengths determined, the following results being obtained:—20° C., 278 lb. per sq. in.; 300° C., 45; 400° C., 0; 500° C., 101; 600° C., 131; 700° C., 124; 750° C., 27; 800° C., 71; 850° C., 186; 1190° C., 260; and 1390° C., 26 lb. per sq. in. By addition of asbestos to the lime-silica mixture, the tensile strength of the product was increased up to a maximum of 377 lb. per sq. in. with 12 per cent. of asbestos. The lime-silica mixture is as plastic as Georgia kaolin, and a vase prepared with it, by moulding, and then hardened by steam-pressure, had a good clear white colour. It is suggested that an architectural building material, to

be used in a similar manner to terra-cotta, could be prepared very advantageously from this finely-divided silica.—A. S.

Portland cement; Lime in —. H. Trachler. Tonind.-Zeit., 1909, 33, 1334—1340.

THE author investigated a number of Portland cements containing high percentages of lime, which had been perfectly clinkered at high temperatures, and had satisfied all the required standard tests for setting, tensile and crushing strengths, and constancy of volume. He found that all these cements began to weaken after six months' keeping under water, a fact which could only be explained by the separation of free lime, present in a state of solid solution. The author draws attention to the two types of Portland cement formulae, taking Schott's formula, $x(2\frac{1}{2}\text{CaO}, \text{SiO}_2) + y(2\frac{1}{2}\text{CaO}, \text{R}_2\text{O}_3)$, as an example of the "bicalcium silicate" type, and Newberry's formula, $x(3\text{CaO}, \text{SiO}_2) + y(2\text{CaO}, \text{R}_2\text{O}_3)$, as typical of the tricalcium silicate type. Taking x in either formula to equal 1, 2, 3, etc., up to 10, y being unity, and calculating the percentages of lime, silica, and iron-and-aluminium oxides (R_2O_3), thus found, a table is obtained by comparison with which, the actual analysis of a cement indicates the excess of lime, i.e., the lime present in the form of solid solution. Corrections have to be made for the magnesia, sulphuric anhydride, and alkalis present, which are calculated as magnesium silicate, calcium sulphate, and sodium silicate respectively, and the magnesium silicate is taken as being capable of binding one molecule of lime in an artificial olivine, having the composition $\text{MgO}, \text{CaO}, \text{SiO}_2$. The author's experiments led him to doubt the existence of tricalcium silicate in Portland cement, and to conclude definitely that a high percentage of lime, in addition to increasing the difficulty and cost of making satisfactory clinker, is invariably injurious to the cement in the course of time.—O. R.

Portland cement; Action of calcium sulphate and calcium chloride on —. Spieglberg. Tonind.-Zeit., 1909, 33, 1289—1290.

THE effects which calcium sulphate and calcium chloride exercise on cement, vary with the composition and properties of the latter. Calcium chloride is most pronounced in its action in those cases where small quantities of calcium sulphate suffice to produce volume changes in the cement. In all cases, however, the author concludes that calcium chloride influences the expansion due to calcium sulphate beneficially; even when the proportion of the latter is unduly increased by adding gypsum to cement, the addition of calcium chloride causes the cement to set to constant volume; the cement at the same time increases in both tensile and crushing strength, more especially the latter.—O. R.

Portland cement; The chemical analysis of —. R. Grimm. Tonind.-Zeit., 1909, 33, 1277—1280.

THE author draws attention to the great divergence in the results of the chemical analysis of Portland cement furnished by different laboratories; in one case under consideration a carefully prepared and thoroughly average sample was divided into six parts: one part was retained and analysed by the laboratory belonging to the manufacturers of the cement, and the remaining five samples were analysed by five different public laboratories in Germany, France, Switzerland, and Spain. There was practically no agreement between the results. The amount of ferric oxide contained (which had led to the rejection of the cement in the first instance), was given as 3.16 per cent. in one of the analyses and as 4.54 per cent. in another, the difference of 1.38 in 100 parts of cement representing a divergence of 43.5 per cent. on the amount of ferric oxide itself. The figures for the other constituents showed even greater discrepancies, and the hydraulic modulus found varied between 1.94 and 2.08. The author briefly reviews the various analytical processes in use at the above, and at other cement laboratories, and recommends that standard methods of chemical analysis should be agreed upon for Portland cement, as has been done in the case of other chemical industries.—O. R.

Portland cement trade of Germany. Board of Trade J., Oct. 28, 1909. [T.R.]

FOREIGN competition in the importation of Portland cement into Germany, as well as the increased production in the country has, during 1909, been remarkable. Exports from Belgium to Germany during the first seven months of the present year amounted to 1,562,685 cwt., as against 1,178,571 cwt. during the corresponding period of last year. Imports into Germany from all sources during the period referred to amounted to 2,528,847 cwt. in 1907, as against 2,022,729 cwt. in 1908. The exports during the first seven months of the present year amounted to 6,646,427 cwt., as against 5,822,141 cwt. during the similar period of 1908. This increase has been due mainly to the demands of Chile, which in the period mentioned took 681,941 cwt., as against 210,253 cwt. in the first seven months of last year. Much larger quantities have also been exported this year from Germany to China, the Dutch East Indies, Brazil, Finland, Norway, and Austria-Hungary.

Sand-lime brick. U.S. Geol. Survey, 1908. [T.R.]

THE sand-lime brick industry in the United States began in 1901. The value of the production in 1903 was \$155,040. In 1907, the maximum of \$1,225,769 was reached, and there was a decrease in 1908 to \$961,226. The number of plants reporting increased from 16 in 1903 to 94 in 1907, with a decrease in 1908 to 87.

PATENTS.

Wood ; Process of preserving — J. M. Nelson, jun., Sherwood, Md. U.S. Pat. 937,008, Oct. 12, 1909.

TIMBER is heated in a suitable bath to a temperature above 100° C., in order to expel a portion of the contained gas and moisture. It is then immersed in a cool preservative solution. Owing to the contraction of the contained gas and moisture by the reduction in temperature, the preservative is readily absorbed. The impregnated timber is again heated above 100° C. and finally cooled in air. —F. R.

Wood ; Process of impregnating — by sudden changes of pressure and exhaustion. M. Boucherie. Fr. Pat. 401,746, Aug. 7, 1908.

THE injection of antiseptic or colouring liquids into wood is retarded by gases and by the residue of the sap. The inventor obviates these difficulties by subjecting the wood in a closed vessel to sudden changes of pressure and to suction, by which means the gas is removed. —H. H. S.

Tar oils [for preserving wood, etc.] ; Process for improving — Gewerkschaft des Steinkohlen-Bergwerkes "Lothringen." Ger. Pat. 213,715, Jan. 15, 1909.

FOR use in preserving wood, etc., tar oils should not have a disagreeable odour, should be of a brownish colour, and as viscous as is consistent with ease of application. These conditions are said to be fulfilled if the tar oil is heated to 200°–300° C. with about 2 per cent. of carbon tetrachloride and a small quantity of hydrochloric acid, and then a portion removed by heating or by treatment with steam. If the proportion of carbon tetrachloride is increased, the hydrochloric acid may be omitted, and no distillation is necessary. —T. F. B.

Cement ; Waterproof — and method of making the same. J. F. Schoellkopf, Assignor to Schoellkopf, Hartford, and Hanna Co., Buffalo, N.Y. U.S. Pat. 930,697, Aug. 10, 1909.

Two parts of quicklime and one part of powdered rosin or colophony are mixed with water and well stirred. Baryta may be used in place of lime. About two per cent. of the resulting mixture added to Portland or similar cement is stated to give a product which is waterproof when set. —J. W. H.

Cement product ; Vitrified — and process of making same. H. C. Todd, Oak Park, and C. Mayr, Chicago Ill., Assignors to Chicago Fireproof Covering Co. U.S. Pat. 935,616, Sept. 28, 1909.

ARTICLES of great hardness are made by shaping them out of a mixture of hydraulic cement and water, with or without the addition of a porous or fibrous "filler," and when set, drying them and impregnating them with a solution of a colloid soluble silicate. —F. R.

Cement ; Manufacture of — M. Trembour, Harzburg, Germany, Assignor to Putnam Development Co., New York. U.S. Pat. 935,617, Sept. 28, 1909.

MOLTEN blast-furnace slag is broken up into small particles, and an acid solution, alone or containing a small quantity of a dissolved coating material, is added, or a finely-divided material is introduced, which forms a deposit around the separated globules of slag. —F. R.

Cement ; Manufacture of — from slag in blast-furnaces. Soc. J. et A. Pavin de Lafarge. Fr. Pat. 401,493, Apr. 1, 1909.

ACEMENT, approximately of the formula, $\text{SiO}_2 \cdot \text{Al}_2\text{O}_3 \cdot 3\text{CaO}$, is made by adding the required quantities of alumina and chalk to the charge of a blast-furnace. —H. H. S.

X.—METALS AND METALLURGY.

Mineral output of British India in 1908. Indian Tr. J., Sept. 23, 1908. [T.R.]

Coal.—The coal industry in India has now assumed very important proportions. The output in 1908 amounted to 12,149,020 tons, as compared with 10,526,468 in 1907. Of the total, 11,559,911 tons were raised in Bengal.

Mica.—There was an increase in the output of mica of 1,289 cwt. As in 1907, Hazaribagh increased its output, while that of Madras again fell, the decrease being 4,516 cwt. There was a great falling off in the demand towards the end of 1908, and several of the smaller mines closed down.

Manganese ore.—The figures for 1907 were 642,082 tons, while last year they reached only 494,942 tons. Of this decrease, 113,375 tons is due to the Central Provinces, which made such strides in the previous year ; while Madras has a decrease of 36,108 tons. In the Bombay Presidency the output has risen from 19,689 tons in 1907 to 22,032 tons in 1908.

Limestone again showed a considerable increase, while the output of salt diminished. The copper mines in the Central Provinces have now reached the producing stage, but the quantity returned for 1908 was only 10 tons. Tin in Burma was only half the quantity returned in 1907, and the chromite worked in Baluchistan dropped to 1,000 tons for the year.

Mineral output of Japan in 1908. Board of Trade J., Oct. 28, 1908. [T.R.]

THE following particulars of the output of minerals in Japan during 1908, as compared with the preceding year, are taken from a return issued by the Japanese Department of Agriculture and Commerce :—

			1907.		1908.

Melting iron in a foundry cupola. H. McCormack. Electrochem. and Met. Ind., 1909, 7, 391—393.

THE author has calculated the amount of heat developed in the melting of an ordinary charge of iron in a foundry cupola, and determined the manner in which the heat is distributed and utilised during the operation. The charge consisted of 240 kilos. of coke, 727 of scrap iron, 363.5 of pig iron, and 70 of limestone; and after the melting, which occupied 67 minutes, 119.5 kilos. of slag, 53 of coke, and 1070 of clean castings were obtained. The average temperature of the molten metal was 1900° C., that of the escaping gases being 800° C. The calculated amount of heat developed was 1,386,383 calories, the amount utilised being apportioned as follows:—

	Per cent. of the total.
Melting and superheating iron	28.14
Heating gases, and loss as carbon monoxide	49.00
Formation and heating of slag	5.60
Heating cupola	13.60
Heating unburned coke	2.90
Loss by radiation and convection	0.58
Unaccounted for	0.18
	100.00

The smallness of the amount remaining unaccounted for is regarded as due to counter-balancing errors, the methods employed not being accurate to this degree. The re-melted iron was found to have gained in silicon, combined carbon, and phosphorus, and to have lost in sulphur, manganese, and graphitic carbon. This effect, which is not in harmony with the experience of Turner, Hoffman, and others, is ascribed by the author to the presence of the slag.—W. E. F. P.

Steel; Slag enclosures in —. W. Rosenhain. Int. Assoc. Testing Materials, 1909. Engineering, Sept. 24, 1909, 409—410.

ATTENTION is called to the importance of further and closer study of the influence exerted upon the strength and safety of steel by the presence within its mass of non-metallic substances, commonly known as "slag enclosures." Their presence is readily seen on microscopic examination. The duplex nature of some of these is

usually explained by the statement that they consist of sulphide of manganese embedded in silicate of manganese, but the author has observed instances of duplex enclosures in which neither of the constituents was really soluble in acids. In wrought iron, containing practically no manganese, there was always a large amount of non-metallic matter and this sometimes showed a well-marked duplex structure. In this case, although sulphide of iron might be present, it seemed probable that the constituents were two different silicates, or possibly oxides, of iron. Stead had suggested that in the case of steel these enclosures were due to the introduction of oxygen either during melting or in the teeming process; this oxygen reacted with the manganese and silicon to form silicates, while the sulphur already in the steels combined with the manganese in the manner shown by Arnold. The obvious remedies were to protect the steel from oxygen during teeming, and to allow it to rest sufficiently long after the addition of manganese to allow the sulphide to rise to the surface, this period of time is probably much longer than usually anticipated. The author points out that the incomplete separation of slag from the metal in the furnace or converter, the violent boiling probably producing admixture of slag and the time taken for settling being much longer than generally thought, the contact of the metal with the tapping hole, the gutter, the ladle lining and the stopper were all sources of contamination by silicious substances. In steel the enclosures were generally found embedded in the ferrite bands, but when they were in the harder pearlite, they were in contact with a material which could not adapt itself to them. Guillet mentions some ship's plates which were accepted and delivered on the usual specified tensile test. On being worked up they developed cracks, and impact tests gave invariably bad results. It was shown that the cracks started from slag enclosures, and the plates would probably have been rejected if impact tests had been made at the works. Stead in a discussion which followed the paper confirmed the remarks which stood in his name, and said that he strongly recommended casting all steel without allowing air to impinge upon it. It was barbaric to cast through air after the extreme care which was given during the process of manufacture. The Congress recommended the appointment of a committee to investigate the influence of slag enclosures upon the quality of the metal.—A. H. C

Spring steel; Heat treatment of — L. H. Fry. Int. Assoc. Testing Materials, 1909. Engineering, 1909, Sept. 17, 369—370.

Using a basic open-hearth spring steel commonly used in America for locomotive carrying-springs, the author has investigated the effect of annealing, the comparative effect of quenching in water and in oil, and the effect of reheating to various temperatures after complete cooling in water and in oil. Ten test-pieces 1 in. in diameter and 14 in. long were cut from the same bar of steel having the following composition: carbon 1.01 per cent.; manganese 0.38 per cent.; phosphorus 0.032 per cent.; sulphur 0.032 per cent.; and silicon 0.13 per cent. The critical point was found to be 1360° F. (740° C.). As the result of experience it was found advisable to anneal the steel from 40° F. to 50° F. (4°—10° C.) above the critical temperature, and to harden the steel from 50° F. to 100° F. (10°—38° C.) above the critical temperature, the exact temperature being determined by the size of the work and the effectiveness of the cooling bath. The author decided to employ the following temperatures: for annealing, 1400° F. (760° C.), for quenching in oil 1450° F. (790° C.), and for quenching in water, 1425° F. (775° C.). The modes of quenching, and the heats to which the temper was drawn were the only variable operations. To anneal the test-pieces they were heated in a lead bath at the above temperature for two hours, and were then allowed to cool with the furnace for fourteen hours. The oil for hardening was at a temperature of 80° F. (27° C.); the water was pure running water at 60° F. (16° C.). Either an oil bath which could be heated by gas to 600° F. (315° C.) or for higher temperatures a lead bath was used for tempering the test-pieces. For testing, the specimens were placed on supports 12 in. apart, and the loads were applied in the middle. It was found by the author that the steel used, when thoroughly annealed as described had an elastic limit of 78,500 lb. (35 tons) per sq. in. or about half the elastic limit obtained when given a "spring temper" or equal to about one-third of the elastic limit of the same steel when quenched in water and drawn to 750° F. (400° C.). The highest elastic limit when quenched in oil at 1450° F. (790° C.) was 187,400 lb. (83.7 tons) per sq. in. and this was obtained when the temper was not drawn after quenching. The higher the temperature of tempering the lower the elastic limit fell. Thus:—Drawing to 400° F. (205° C.) gave 177,600 lb. (79 tons) per sq. in.; drawing to 500° F. (260° C.) gave 160,400 lb. (71.6 tons) per sq. in.; drawing to 560° F. (292° C.), gave 137,500 lb. (61 tons) per sq. in. When the steel was quenched at 1425° F. (775° C.) in water, and not tempered, it was brittle and broke at 212,000 lb. (94.6 tons) modulus of rupture, the elastic limit being the same as the modulus of rupture, the deflection of the breaking point being 0.171 in. Tempering to 500° F. (260° C.) gave an elastic limit of 219,800 lb. (98.5 tons) still equal to the modulus of rupture; tempering to 750° F. (400° C.) gave the highest elastic limit viz. 240,800 lb. (107.5 tons) with a still higher modulus of rupture of 389,000 lb. (174 tons); at 900° F. (482° C.) the elastic limit fell slightly, while on tempering at 1050° F. (565° C.), the elastic limit fell to 180,700 lb. (80.7 tons) and the test piece did not break under a deflection of 1.1 in. The modulus of elasticity was found to be practically constant, and independent of the heat treatment; it was however, difficult to determine accurately, and values varying from 27,150,000 to 30,420,000 were obtained. The author concluded that steel with 1 per cent. of carbon when quenched in water from above its critical temperature, was usually too hard and brittle to be used for making springs or tools.—A. H. C.

Titanium; Influence of —, on steel, especially on steel rails. E. von Maltitz. Stahl u. Eisen, 1900, 29, 1593—1602.

The addition to steel in the ladle, after ferro-manganese or ferro-silicon, of half to one per cent. of ferro-titanium (containing 10—15 per cent. of titanium) greatly improves the quality of the steel. It probably does this by combining with the last traces of oxygen, and also with any

nitrogen in the steel, and, by thus lessening the amount of gas present in the metal, making it more compact and homogeneous. Photographs are given of ordinary Bessemer rails and of "titanium-steel" rails laid down and used under similar conditions, and figures showing the wear, which prove that the "titanium-steel" rails are from three to six times as durable as the others. The increased cost of production is probably 7 or 8 shillings per ton. The tensile strength of this steel is stated to be from 60 to 75 per cent. higher than that of ordinary Bessemer steel.—J. T. D.

Sparks as indicators of the different kinds of steels. M. Bermann. Int. Assoc. Testing Materials, 1909. Engineering, 1909, Sept. 17, 370.

In grinding metals the size of the spark depends upon the size of the grain forming the emery wheel, the speed of cutting, the nature of the metal, and the pressure with which the wheel bears against the metal. The initial temperature of the sparks is influenced principally by the cutting power and cutting speed of the emery wheel, and in a minor degree by the nature of the material ground. The influence of the emery wheel, however, far outweighs that of the quality of the steel. The author states that the spark test is so sensitive that it will give very clear indication of a difference of 0.01 per cent. of carbon in a steel. If bars had been wrongly arranged in store rooms, when tested with a revolving emery wheel the spark-ray would give precise information of the quality of the metal forming the bar; for instance, pointed branching lines denoted carbon steel (Siemens-Martin); leafy ends of the branching lines showed Siemens-Martin steel of high carbon percentage; spark pictures, with a "blossom-branch-like" appearance, indicated ordinary tool steel. The spark-test could be used in the course of the Siemens-Martin process, to test the bath and for the inspection of the finished material, as a guide in the hardening of tools, in inspecting wire for the manufacture of springs, and in the forge to distinguish good iron from that which was difficult to weld.

—A. H. C.

Iron alloys; Some physical characteristics of — C. F. Burgess and J. Aston. Electrochem. and Met. Ind., 1909, 7, 436—438.

The authors have studied qualitatively the mechanical properties of alloys of a large number of elements with electrolytic iron (see this J., 1904, 667) of 99.97 per cent. purity, the alloys being practically free from carbon. The alloys were prepared in ingots of about 1 lb. weight by heating the components together in a covered graphite crucible, lined with magnesia, in an electric resistance furnace. The results, which are given in tabular form, showed that qualitatively the characters of the various alloys in regard to forging did not differ greatly from those of similar commercial alloys (i.e., containing carbon). Chromium, manganese, molybdenum, nickel and tungsten promoted self-hardening properties even in absence of carbon, and many of the alloys of electrolytic iron with these five metals would make satisfactory lathe tools either in their air-hardened condition or after quenching. Alloys of electrolytic iron with combinations of two or more of the metals mentioned were generally so hard, that test-bars could only be obtained by grinding, but by choosing a suitable temperature and taking the precautions found necessary in the working of high-speed steels, nearly all of them could be forged.—A. S.

Alloys of electrolytic iron with arsenic and bismuth. C. F. Burgess and J. Aston. Trans. Amer. Electrochem. Soc., 1909, 15, 369—389.

The pure iron used in the investigations was electrolytically refined from Swedish iron bars. After two refinings the pure iron content was 99.971 per cent. (See this J., 1904, 667.) This material was melted with the alloying metal in a dense electrically-shrunk magnesia crucible, with a magnesia cover; this crucible was placed in a graphite crucible and the whole embedded in granu-

to the tube mills, mixing them with the ordinary pulp, until they are so fine that they float off with the tailings. In this system concentration is used as an aid to fine grinding. The ground pulp from the stamps containing about 10 of solution to 1 of ore, goes to a "Dorr" classifier A (see fig.), the overflow from which, consisting of particles all passing 150-mesh, is condensed in the pulp thickener, B, to 4 to 1. The coarser part of the pulp goes to the tube mill or regrinder (D). It contains the sands from which the metal has not yet been completely liberated, the pyrites, and coarser particles of silver sulphides and gold. The overflow of the classifier having been properly thickened in B is concentrated on the slime tables (C). The concentrates from these tables instead of being sold are returned to the pump (F) which receives the discharge of the tube mill (D) and returns them to the classifier again. The concentrates are thereby kept in circulation, till they are fine enough to float off the slime tables into the tailings with which they are led to the pulp thickener (E), where they are rendered fit for treatment with cyanide. These concentrates are now so fine, that they behave just like the metals in the ordinary pulp. Extraction is complete in 24 hours or even less; there is no reprecipitation and the cyanide consumption is in proportion to the metallic contents of the ore. The additional cost of this regrinding is insignificant when compared to that of disposing of the concentrates to the smelter or subjecting them to a special treatment.—A. H. C.

Oxidation and cyanidation. H. A. Megraw. Eng. and Min. J., 1909, 88, 645-646.

OXIDATION plays a most important part in the reactions of cyanidation. As far as the extraction of gold is concerned, it is the general opinion that air itself is the best and cheapest oxidising agent, although chemical oxidising reagents have been used with some success. With silver, however, no really satisfactory result has been obtained. The volume of silver in a commercially treatable ore is so great, compared with a gold ore of equal value, and the reactions so much more involved, that a longer time of treatment has come to be considered necessary. In the treatment of a silver-gold ore by different chemical oxidisers, Caldecott has shown that barium peroxide gave the best result, in the case of gold, with an extraction of 89.7 per cent. in six hours using 0.1 per cent. of the oxidising agent. In the case of silver, oxygen under 100 lb. pressure gave the best result, with an extraction of 79.4 per cent. in six hours. The diagram shows the results of experiments made on slimes in circular, flat bottom tanks, air being introduced from a compressor through a number of jets fixed in the bottom of the tank. Curve *a* shows the result of treatment by agitation and oxidation by free air alone, *b* shows the result of circulation with a centrifugal pump after 48 hours' treatment by free air agitation, and *c* shows the result of the use of the centrifugal pump alone, during the entire time of treatment. As the result of many experiments the author concludes that the use of chemical oxidisers is inadvisable owing to the expense, and because the introduction of other and useless chemicals further complicates the already complex reactions. The author has devised a method of deriving oxygen from water electrolytically, and adding it in a fine stream to the slime pulp under treatment by means of a small pipe leading from the oxygen tank into the suction of the centrifugal pump

used for circulation. Although the cost would be small the author is unable to make any comparison between the cost of his method, and that of the somewhat similar suggestion of Mosher (Min. and Sci. Press, May 15, 1909) in which the use of ozone from air is recommended.

—A. H. C.

Silver and its alloys: Solubility of — in mixtures of acids. E. Panmain. Gazz. chim. ital., 1909, 39, 11, 234-239.

IN the manufacture of silver coins the coating of copper oxide produced by the repeated annealings to which the metal is subjected, is removed by treatment with dilute sulphuric acid of 2°-3° B. heated to about 100° C. In this operation some silver is always dissolved along with the copper. Moreover Carey Lea (Z. anorg. Chem., 1893, 3, 180) has stated that pure silver, if finely-divided, is slightly soluble in dilute sulphuric acid. On the other hand the generally accepted view is that silver is soluble in concentrated, but insoluble in dilute sulphuric acid, and technical processes for the separation of silver from gold on the one hand and from base metals on the other have been founded on this view. The author's experiments on the subject have shown that silver whether pure or in the form of an alloy (Italian coinage metal) containing 16.5 per cent. of copper is not dissolved by pure sulphuric acid of a concentration below 60° B. In presence of impurities in the acid, however, silver is dissolved even by dilute sulphuric acid. In the technical separation of silver from gold, it would be preferable to use a mixture of sulphuric and nitric acids, which would dissolve the silver at a lower temperature than sulphuric acid alone, and with a consumption of nitric acid of about one-half that required when pure nitric acid is employed. In the removal of the coating of copper oxide from silver-copper alloys, such as silver coinage alloys, and in the separation of base metals from silver, pure dilute sulphuric acid should be employed; even in presence of the impurities contained in the commercial acid, or in tap water, some silver is dissolved.—A. S.

Copper-slags: Metal losses in —. L. T. Wright. Trans. Amer. Inst. Min. Eng., 1909, 817-820.

THE copper content of a well-settled slag is not reduced by holding the slag in a molten condition nor can fine-grinding and elutriation of the solid slag be made to give a product containing more copper than the average. Also, the ratio of the silver and gold to the copper is not the same in the slag as in the matte, the proportion of silver being less and of gold much less. For these reasons the author considers the copper is present in thoroughly settled slags in a state of solution and not in the form of "prills" of matte. For every increase of 1 per cent. of copper in 15-45 per cent. mattes, the copper in the accompanying slags increases on an average 0.005 per cent., and, other things being equal, a difference of 1 per cent. of silica in the slag makes a difference of about 0.01 per cent. in its copper content. The silver and gold in copper-slugs may be almost entirely removed by keeping them while molten in contact with matte poor in precious metals, although the percentage of copper may remain unaltered. O. F. H.

Copper: Comparison of the properties of — containing nickel and arsenic respectively. W. Stahl. Metallurgie, 1906, 6, 610-612.

SMALL percentages of nickel increase the tensile strength of copper without decreasing the elongation and contraction of area at fracture. The molten metal, however, more readily absorbs gases, and special precautions are necessary to avoid this. Small percentages of arsenic increase the tensile strength, malleability, and ductility, and when sufficient arsenic is present, the molten metal does not absorb gases. The presence of arsenic counteracts the harmful effect of bismuth as an impurity, and

in conjunction with nickel, increases the hardness of the copper. The strength, etc., of the two classes of metal are as follows:—

	Copper containing a few tenths per cent. of nickel.	Copper containing 0.30—0.35 per cent. of arsenic.
Tensile strength (kilos. per sq. mm.)	22—23	22.0—23.4
Elongation (per cent.)	39.5—46.0	33.0—44.0
Contraction of area (per cent.)	50.5—67.0	47.0—62.0

The tensile strength increases or decreases with the percentage of arsenic outside the limits given, but the elongation and contraction cannot be markedly increased by decreasing the percentage of arsenic. Copper containing nickel retains its properties unchanged when subjected to considerable fluctuations of temperature and of stress, but it is doubtful whether this is the case with copper containing arsenic (compare Friedrichs, *Metallurgie*, 1905, 487; 1908, 532). The author concludes that copper containing nickel is more suited to modern requirements.

—A. T. L.

Bismuth; Influence of — on wire-bar copper. H. N. Lawrie. *Trans. Amer. Inst. Min. Eng.*, 1909, 857—866.

BISMUTH varying in amount from 0.005 per cent. to 0.4 per cent. was added to the purest wire-bar copper melted in graphite crucibles. Samples were withdrawn and cast into bars when the copper was judged to be at "tough-pitch." These bars were subjected to tensile and rolling tests. It was found that some of the bars containing bismuth had a fine-grained fracture, while others gave a columnar fracture, this difference being due probably to a difference of "pitch" at the time of pouring. The alloy containing 0.2 per cent. of bismuth had a very fine-grained, "tough-pitch" fracture and gave a tensile strength of 3500 lb. per sq. in. greater than the best pure copper bars cast in these experiments. The author considers that, if cast at "tough-pitch," an alloy of copper with 0.18 per cent. of bismuth is stronger than pure copper. With regard to the effect on the rolling properties, it was found that the limiting quantity of bismuth which can be present without appreciably lowering the malleability and ductility of the copper is less than 0.005 per cent., whether the metal is to be rolled hot or cold. If this limit be exceeded, the ductility of the copper is so lowered as to interfere with the process of wire-drawing.—O. F. H.

Copper and brass; Notes on some probable causes of the corrosion of —. E. L. Rhead. *Inst. of Metals*, Oct., 1909. [Advance proof.]

THE author has experimented upon copper and brass with various corroding liquids, including dilute solutions of ferric chloride, hydrochloric acid, and common salt, the last being used alone and also in conjunction with carbonic acid gas, ammonium nitrite, and hydrogen peroxide. The ammonium nitrite and carbonic acid gas were introduced to show the possible effects resulting from the use of sea water contaminated by sewage, while the hydrogen peroxide was used to produce an effect similar to that of dissolved oxygen. Plates of hard and soft copper, and of brass, were submitted to the action of dilute ferric chloride solution for from 20 to 48 hours, note being taken of the amount of metal dissolved in each case. In most instances the loss on the hard copper was greater than that on the soft; but whereas, in the latter case, the corrosion of the surfaces was fairly uniform, in the former the action was found to have proceeded unevenly and in more or less distinct bands parallel to the direction of the rolling of the plates. The brass plates, which were polished on one side, became enriched in copper round the end edges, on the polished side, and in scratched or tool-marked places. Further experiments upon hard, soft, and polished copper, with the other corroding liquids enumerated, indicated that hard copper shows greater susceptibility to attack than

the soft metal; and the presence of carbonic acid gas was found to promote the corroding action in every case. In an experiment upon a strip of hard brass, which was softened at one end and then bent into Ω -form, the two limbs were placed in a solution containing 10 per cent. of hydrochloric acid and 5 per cent. of copper chloride. After 12 hours, it was found that while the softened limb was scarcely affected, the other had become seriously corroded, especially on the inner side, the corrosion being most marked in parallel lines running across the strip in the direction of the rolling. In the light of these results, it would seem that corrosion of this kind might be due to the unequal hardness resulting from unequal pressures during the cold rolling of the metal, the harder portions being electro-positive to the softer, and consequently dissolving more readily. This may facilitate the explanation of some of the more rapid cases of corrosion met with in practice; for example, that of the tubes of surface condensers. The roughness caused by the action thus set up may form the points from which the liberation of the gases contained in the condensing water takes place, and any tendency to concentrate the evolution of gas would also tend to localise the corrosion.—W. E. F. P.

Copper-zinc alloys: a study of volume changes. T. Turner and M. T. Murray. *Inst. of Metals*, Oct., 1909. [Advance proof.]

Fig. 1.

Fig. 2.—Continuous line Shore scleroscope.
Broken line Brinell test.

The extensometer designed and previously described by Turner (this J., 1906, 538) was used to obtain shrinkage curves of the alloys of the copper-zinc series, the test bars being 12 in. long and $\frac{1}{2}$ in. square section. A cooling

curve of each alloy was taken simultaneously with the shrinkage curve by means of a thermo-couple inserted in the test bar, and the micro-structures of the cast bars were examined. Many of the alloys gave an expansion during solidification, particularly those between the compositions 9 per cent. and 26 per cent. of copper (see Fig. 1). The maximum expansion in the series is at the composition 14.76 per cent. of copper, and other maxima occur at about 80 per cent. of copper and at about 50 per cent. of copper. The alloys containing 60 per cent. and 40 per cent. of copper give no expansion, and the equilibrium diagram shows that at these compositions the solidus and liquidus curves coincide. On the other hand, the maximum expansions during solidification are observed where the solidus and liquidus are most widely separated. The solid solutions, δ and ϵ , both expand considerably during solidification, and the change of δ to ϵ is considered to be the cause of the greater part of the very pronounced maximum expansion at 14.76 per cent. of copper. The hardness of the alloys was tested by the Shore scleroscope and by the Brinell test, similar results being obtained by each method (see Fig. 2). A very well marked maximum hardness was found at 40 per cent. of copper, this alloy being harder than mild steel. The authors are of the opinion that the existence of the compound, Cu_2Zn_3 (39.36 per cent. of copper), is well established. Curves showing the total shrinkage of $\frac{1}{2}$ in. bars and $\frac{1}{4}$ in. bars of these alloys are also given. From these curves it is seen that there is a well-defined maximum total shrinkage at 40 per cent. of copper, and a minimum at about 20 per cent. of copper. In the case of the $\frac{1}{2}$ in. bars there is also a maximum at 65 per cent. of copper which is absent in the curve for the $\frac{1}{4}$ in. bars. The fact that alloys containing about 65 per cent. of copper shrink less in thin sections than in thick may account in some cases for the failure of brass castings.

—O. F. H.

Alloys: The constitution and properties of the aluminium-copper-tin — C. A. Edwards and J. H. Andrew. Inst. of Metals, Oct., 1909. [Advance proof.]

BEFORE the constitution of a ternary alloy, ABC, can be studied, it is necessary to know that of the binary alloys, AB, BC, AC. The constitution of the three series, aluminium-copper, aluminium-tin, copper-tin, having been investigated, and there being a desire to substitute aluminium for tin in brasses, and other industrial alloys, the authors have studied the effect of a third metal on the transformations of such complicated alloys as aluminium-copper, and copper-tin. An equilateral triangle can graphically represent a triple alloy, each corner being one of the metals, while any point within it represents a mixture of the three metals, and perpendicular lines to the sides from this point are proportional to the percentage of the metal located at the opposite corner. A solid right-triangular prism can illustrate temperature and concentration, by letting the axis of the prism represent temperature. The boundary lines of the different phases were determined by casting the alloys in chill, annealing at the desired temperature for such time as considered necessary and then quenching, finally examining the alloy by the microscope. The authors illustrate the paper with twenty-four microphotographs, and by means of five triangular diagrams give the constitution of the alloys for the liquid state, the first and second periods of solidification, and at the ordinary temperature. It is shown that (1), no ternary compound is deposited from the liquid alloys; (2), no ternary eutectic is formed; (3), while the inversion of the compound, Cu_3Al , in the series copper-aluminium takes six weeks at 540° C. (Curry), in the presence of tin the inversion takes place in five hours; (4), the alloy containing 10 per cent. of tin and 9 per cent. of aluminium has the same structure at 900° C. as at 500° C., but at intermediate temperatures quite different structures are obtained. From a practical point of view, it is pointed out that alloys possessing useful mechanical properties are confined to very limited areas. All the others are very brittle, and in the far greater number the tin does not mix to form homogeneous alloys; no advantage is to be gained by adding tin to those alloys containing the compound, Cu_2Al .

The most important alloys of copper-tin are those containing 9—14 per cent. of tin. One containing 10 per cent. of tin has a breaking strain of 20.6 tons per sq. in. and an elongation on 2 in. of 40 per cent. Under the same conditions an alloy containing 7.5 per cent. of aluminium and 92.5 per cent. of copper breaks at 21.3 tons per sq. in. with an elongation of 71 per cent. From the results obtained the authors consider that an alloy containing 6.5 per cent. of aluminium and 5.5 per cent. of tin will have the same properties as an alloy of 10 per cent. of tin and 90 per cent. of copper. Such an alloy would be cheaper than the copper-tin, and have a lower specific gravity, and the authors are hopeful of being able to obtain definite figures for a plastic metal capable of being moulded between 232° C. and 540° C. — A. H. C.

Zinc: The technical assay of — H. W. Greenwood and F. J. Briscoe. Inst. of Metals, Oct., 1909. [Advance proof.]

WITH a view to determining their relative value for technical purposes, the methods in general use for the estimation of zinc have been examined and compared by the authors. Only volumetric and gravimetric determinations are considered, electrolytic processes being generally regarded as too troublesome for technical work. Of the volumetric processes, the authors prefer Schaffner's method (titration with alkali sulphide) as being of the widest application and affording the highest degree of accuracy. This method was found to give the best results with the assay solution at a temperature between 60° and 80° C., the volume being 150 to 170 c.c. and containing excess of ammonia. The indicator employed was ferric hydroxide (formed in the assay solution by the addition of 1 drop of a strong solution of ferric chloride), and corrections for the excess volume of liquid and for the excess of sulphide required to blacken the indicator were applied. The ferrocyanide method is recognised as being very rapid and fairly accurate, but in the authors' opinion, its value is greatly impaired by the unsatisfactory end point of the titration when a uranium indicator is employed. Ammonium tetramolybdate is stated to be nearly twice as delicate an indicator as the uranium salt, and its use is recommended for this purpose. Walker's volumetric method, which consists in precipitating the metal as zinc-ammonium phosphate, dissolving the precipitate in excess of standard acid and titrating with standard alkali, is regarded as being of limited application only, the results being seriously affected in the presence of lime and magnesia. Of the gravimetric methods, precipitation as carbonate, with subsequent ignition to oxide, gave consistently high results, due to the practical impossibility of washing the precipitate free from sodium carbonate. The addition of excess of mercuric chloride before the precipitation of small quantities of zinc as sulphide was found of advantage in many cases, the mercuric sulphide being subsequently expelled by ignition. Traces of zinc were satisfactorily detected by the calcium zincate method, consisting in the addition of an excess of milk of lime to the solution, boiling well and filtering. The precipitated calcium carbonate then contains the zinc as calcium zincate, and the metal may be separated (as sulphide) by dissolving the precipitate in acetic acid, adding excess of ammonium acetate and saturating with sulphuretted hydrogen. For the estimation of zinc in alloys, precipitation as zinc-ammonium phosphate, with subsequent ignition to the pyrophosphate, was found to give very accurate results, and this method is regarded as the most satisfactory gravimetric process for the determination of zinc. In the analysis of zinc-aluminium alloys, an indirect process was adopted in which the proportions of the metals were calculated from the amount of hydrogen evolved by the action of a known weight of the alloy upon hydrochloric acid. The results were very satisfactory when the proportions of the metals were nearly equal, but less concordant when the alloy was comparatively poor in zinc. — W. E. F. P.

Spelter: Production of pure — J. S. G. Primrose. Inst. of Metals, Oct., 1909. [Advance proof.]

It is said that in one operation, zinc of 99.7 to 99.9 per cent. purity can be obtained from galvanisers "dross,"

"ashes," and "hards," by passing the volatilised products from the retorts, through fume filters. The flow of the gases is retarded in proportion to their respective densities, the lead fume being condensed within the filter, while the lighter zinc fume passes through to the condenser. Tests made on a refractory lead-zinc "middlings" from Broken Hill, containing about 48 per cent. of zinc and 13.75 per cent. of lead, yielded 5 tons of high grade spelter from 15 tons of the middlings. The first and second tappings only contained 0.68 and 0.85 per cent. of lead respectively. Curves are given showing the production and prices of zinc from 1875 to date, together with tabulated details of the various tests.—F. R.

Galvanised and other zinc-coated metals: Testing of —. W. H. Walker. Amer. Soc. for Testing Materials, 1909. Electrochem. and Met. Ind., 1909, 7, 440—442.

THE coatings produced by the hot-galvanising, wet-galvanising (electrolytic), and sherardising processes (see this J., 1909, 399) each present different characteristics, and the Preece copper sulphate test is not of much value for judging the efficacy of the respective coatings. For the detection of pin-holes and cracks, immersion in a concentrated solution of caustic soda at 100° C. is recommended, when evolution of hydrogen will take place at any spots where unprotected iron is present (see also this J., 1909, 605). A coating of electrolytically deposited zinc is less porous and of better quality, the lower the current density at the cathode during the deposition. By heating in a concentrated solution of caustic soda in presence of metallic iron, the pure zinc in galvanised iron is dissolved, but not the zinc-iron alloy, and the weight of zinc per unit area can thus be determined. For determining resistance to corrosion of galvanised iron, a piece of the metal of known area is immersed in dilute standardised acid and the rate of evolution of hydrogen observed: this should indicate the relative durability of the coating, the rate of evolution from inferior products reaching a maximum in a few minutes, whilst with better products, a much longer time is required. With respect to galvanised iron wire for fences, it is stated that heavier coatings of zinc are needed than those generally provided, and it is suggested that by mechanically working the coated wire in dies or grooved rollers, the crystalline character of the zinc might be destroyed and the flexibility and ductility of the coating improved.—A. S.

Tin; A new infectious disease of —: the "forcing disease" [*Forcierkrankheit*]. E. Cohen. Chem. Weekblad, 1909, 6, 625—640. Chem. Zentr., 1909, 2, 1207.

THE phenomenon described by Hasslinger (this J., 1908, 1116) as "a new form of tin pest," is quite distinct from the effect generally known as "tin pest" (see this J., 1908, 1155); it is due to strong mechanical actions on the metal, and may be produced artificially both by chemical and mechanical means. If a mixture of potassium chlorate and hydrochloric acid be allowed to act for one minute at the ordinary temperature on tinplate, the so-called *Moiré métallique* is produced. If the treated spot be now rinsed with water, dried with a soft cloth, and then pressed against pure tin foil and the whole heated to 184° C., the effect observed by Hasslinger is produced: the tin foil becomes dull, and is capable of infecting other samples of tin. Further, if a bright piece of tinplate be struck carefully in an oblique direction with a hammer so that the bright surface layer is removed, then the dull spots so produced are also capable of infecting other samples of tin. Apparently "forced tin" (rolled tin, tinplate, tin foil) is to be regarded as a metastable system. At the ordinary temperature the change to the stable form proceeds with extreme slowness, but by rise of temperature or by infection with the stable modification, the velocity of the change is considerably increased.—A. S.

Bag house; The — and its recent applications. W. C. Ebaugh. J. Ind. and Eng. Chem., 1909, 1, 686—689.

IN an article furnished with numerous references, the author describes the modern bag-house of a lead smelting works, in which the fume from the lead blast-furnace

is forced through a large number of long narrow wooden bags in order to recover the solid matter present. This method has been in use for a long time in the case of zinc and lead furnaces, but until recently was not practicable for fumes from copper furnaces and roasters. Rhoades and Sprague, however, found that by addition of zinc oxide, produced for example in auxiliary furnaces from zinc "middlings," the small proportion of sulphur trioxide present in fumes from copper blast-furnaces, reverberatory furnaces, and converters, could be neutralised, and the bag-house method could then be used with advantage. — A. S.

Solders: Surface appearance of —. C. O. Bannister and H. J. Tabor. Inst. of Metals, Oct., 1909. [Advance proof.]

AS the sale of solder is influenced by its appearance, investigations were made into the conditions which affect the surface, which latter should be smooth, even, white, and with a furrow running along the centre. It was found that the addition of 2 per cent. of antimony to tinman's solder gave a bright, clear smooth surface, superior in appearance to the alloy containing only lead and tin, but larger amounts of antimony produced a rough, spotted, frosty or pimply surface. The presence of copper up to 0.5 per cent. gave good surfaces, which however, had a tendency to blister; larger quantities gave dull, flat, crystalline surfaces. Zinc, even in extremely minute quantities was highly detrimental, as little as 0.01 per cent. causing the whole of the surface to become minutely crystalline. Bismuth up to 1 per cent. appeared to have no effect. Silver up to 0.2 per cent. gave a good smooth surface, with an opalescent effect, which on increasing the percentage of silver, developed into a very white crystalline surface. The condition of the pouring largely affects the surface appearance, the best results being obtained when the alloy is poured at a moderate temperature into a mould of poor conducting material, such as marble, and allowed to solidify gradually.—F. R.

Soldering; Chemistry of preparations for use in —. A. Lippmann. Z. angew. Chem., 1909, 22, 2042—2044.

EXAMINATION of a large number of defective soldered joints in electric wires and cables has shown that the prejudice against acid soldering preparations is not justified by facts, preparations of zinc chloride being found superior in every way to those containing ammonium chloride. The latter have a much more marked deleterious after-effect than even free hydrochloric acid, and the gradual addition of ammonia, drop by drop, to a preparation of ammonium chloride was found to lead to worse results in proportion to the amount added; neutralisation with sodium hydroxide rendered the preparation useless.—F. SODN.

Titanium; Metallic —. H. Kaiser. Dissertation, Munich. Stahl und Eisen, 1909, 20, 1663—1664.

REFERENCE is made to the earlier workers, including Moissan who with a high current-density current in an electric furnace obtained titanium containing 4.8 to 15.3 per cent. of carbon, along with the nitride and blue oxide. The author prepared pure potassium titanofluoride, and reduced this with sodium, extracting the mass with water and alcohol. A product was finally obtained containing 85.6 per cent. of titanium, 3.27 of iron, 2.67 of hydrogen, 0.42 of carbon, and 7.99 of oxygen. Allowing for this oxygen as titanous oxide, the product contained 61.61 per cent. of metallic titanium. Experiments were also carried out with commercial potassium titanofluoride. The pure product had a specific gravity of 3.988; it absorbed 19.12 per cent. of nitrogen at about 1250° C. (TiN requires 22.58 per cent.). Employing the aluminium method of Wöhler, a product was obtained containing 33.72 per cent. of titanium, 45.17 of aluminium, and 1.31 of silicon, approximating to Al_3Ti_2 , with a specific gravity of 3.348. This material was compressed under great pressure, saturated with hydrogen, and electrically fused in a vacuum vessel, distilling off the aluminium. Its melting point was between 2200° C.

and 2400° C. The pure fused titanium was silver-white in colour, and contained 97.41 per cent. of titanium, 1.56 of hydrogen, and 0.30 of carbon. At 1360° C. it absorbed 23.31 per cent. of nitrogen. Its specific gravity was 5.174, specific heat 0.1418, and heat of combustion 2031 cal.—A. H. C.

Colloidal thorium. E. Wedekind and H. Baumhauer. *Z. Chem. Ind. Kolloide*, 1909, 5, 191—193.

ZIRCONIUM is already known in the colloidal condition; the authors found that titanium shows very little tendency to become colloidal, but thorium assumes the colloidal condition very readily. Metallic thorium, prepared by the authors in a very finely-divided form, was ground very finely with cold dilute acetic acid in a glass mortar with roughened surface. On washing with cold water a portion of the metal passed through the filter in the colloidal condition at a certain stage of the process. The filtrate was rather intensely coloured and grey and opalescent by reflected light; when sufficiently diluted it was brownish by transmitted light. The hydrosol is fairly stable, but less so than that of zirconium: it is readily coagulated by alkaline reagents, but stable towards dilute mineral acids and acetic acid. It is coagulated by freezing. In an electric field the thorium particles in the dialysed hydrosol wander to the cathode. Under the ultramicroscope bright and almost colourless particles in rapid motion were observed. It was found that 0.0235 grm. of colloidal thorium, as hydrosol, was as radio-active as 0.111 grm. of metallic thorium suspended in water. The radio-activity of thorium hydrosol is less than that of a solution of the same amount of thorium as nitrate. The corresponding thorium gel was dried at a low temperature in a high vacuum and analysed by the method used by Wedekind and Lewis for zirconium: it contained only 20.5 per cent. of metallic thorium and 78 per cent. of thorium oxide.—E. F.

Testing enamelled sheet steel wares. Orton. See VIII.

Specific heats of silicates and platinum. White. See VIII.

PATENTS.

Steel and other metallurgical processes; [Crucibles for] manufacture of —. A. Reynolds, London, Eng. Pat. 9383, May 30, 1908.

IN processes in which the material of the crucible (fireclay or the like) enters into the reactions, the lid of the crucible is provided with rods of the same or similar material which dip into the charge.—O. F. H.

Iron; Method of refining —. P. Sejournet, Paris. Assignor to Soc. Electro-Metallurgique Française, Froges, France. U.S. Pat. 928,551, July 20, 1909.

LOW-CARBON steel is melted in an electric furnace and then cooled until partly solidified. The contained iron oxide and carbon segregate on cooling and then react with each other, with evolution of carbon monoxide. The temperature is maintained at the necessary point until the carbon is practically eliminated, and if desired, the excess of oxide is removed by the addition of a non-carburised de-oxidiser, such as metallic aluminium. The refined metal is reheated under non-carburising conditions and cast into moulds.—F. R.

Iron ore; Method of treating —. J. T. Jones, Iron Mountain, Mich., Assignor to Jones Step-Process Co., Duluth, Minn. U.S. Pat. 930,764, Aug. 10, 1909.

THE ore mixed with coal is passed through a non-oxidising atmosphere of gradually increasing temperature, by which the ore is first reduced and then very highly heated, without, however, melting the slag constituents. The "sponge" produced is allowed to cool or treated at once in a balling or other furnace. A rotary kiln is suggested as a suitable apparatus for carrying out the process. It is stated that the final high temperature employed renders the spongy mass less liable to oxidation on exposure to the air.—J. W. H.

Nickel-steel scrap; Recovery of —. R. H. Watson, Monhall, Pa. U.S. Pat. 934,864, Sept. 21, 1909.

NICKEL-STEEL scrap is melted in an open-hearth furnace with the necessary amount of carbonaceous material. The excess of carbon is then reduced and a steel of substantially the same composition as the scrap, produced.—F. R.

Metal; Permanent magnetic —. S. E. Gertler, Assignor to C. F. Splittdorf, New York. U.S. Pat. 936,530, Oct. 12, 1909.

THE metal comprises a tungsten-steel containing less than 5 per cent. of aluminium. It may contain a variety of elements but the composition is: tungsten, 5.25 per cent.; carbon, 0.65; silicon, 0.15; manganese, 0.25; chromium, 0.20; sulphur and phosphorus, 0.02 or less; and aluminium, 2.50 per cent., with the remainder iron, is instanced.—C. A. W.

Bessemer converter. G. J. Stock, Darlington, England. U.S. Pat. 935,615, Sept. 28, 1909.

THE converter, which is rotatable about both horizontal and vertical axes, is adapted for either melting a charge or converting it, the tuyères being provided with means for supplying both fuel and air. An economiser, which can be moved into or out of connection with the converter, enables the waste heat generated during the melting operation to be used for heating the blast required for the converting.—F. R.

Blast-furnaces and converters; Method of operating —. J. Gayley, New York. U.S. Pat. 935,628, Sept. 28, 1909.

IN order to obtain uniform working in blast-furnaces and converters, the air for the blast is passed through refrigerating chambers to reduce it to a uniform temperature and render its content of moisture low and uniform. These conditions are maintained by means of protected conduits for the passage of the air to the blowing engines.—F. R.

Blast-furnace. E. B. Cook, Pottstown, Pa. U.S. Pat. 936,308, Oct. 12, 1909.

PART of the upper portion of the lining of a blast-furnace is protected by a series of small separated plates of high-carbon steel, held in place by tangs of metal fitted between the brickwork, and anchored, if desired, in a concrete backing.—F. R.

Ores; Apparatus for concentrating —. G. L. Whitcombe, Johannesburg, and A. K. Cox, London. Eng. Pat. 13,366, June 23, 1908.

THE concentrator consists essentially of two concentrically arranged cylindrical vessels connected by a helical partition. The water containing the fine ore in suspension is led under pressure into the annular space, and is discharged tangentially at the bottom into a turbine, which rotates a screw conveyor within the inner vessel. The bottom of the larger vessel is fitted with a series of graduated slots through which the concentrates fall; the lighter material passes up through the inner vessel, assisted by the screw conveyor, and is discharged at the top. Means are provided for automatically clearing the slots and for removing "float" gold if present.—F. R.

Aluminium; Methods of making fusible compounds of — and recovering aluminium therefrom. L. C. Keogh and C. A. Douglas, Ottawa, Canada. Eng. Pat. 18,356, Sept. 1, 1908.

ANHYDROUS aluminium sulphate, preferably mixed with carbon, is added to a molten mass consisting of one or more of the sulphides or haloid salts of alkali or alkaline-earth metals. The fused mass containing aluminium sulphide which results, constitutes an easily decomposed electrolyte from which the aluminium can be recovered. (Reference is directed to Eng. Pats. 97 and 362 of 1883; 2002 of 1890; 20,604 of 1893; 23,707 of 1895; 8072 and 11,555 of 1896; 26,046 of 1897; 16,555 of 1899;

and 964 of 1903; this J., 1883, 382, 478; 1891, 553; 1894, 947; 1896, 544, 658; 1897, 445; 1898, 159; 1899, 1030; 1903, 805.)—O. F. H.

Furnaces for volatile metals. W. Hommel, and The Metals Extraction Corporation, Ltd., London, Eng. Pat. 19,667, Sept. 18, 1908.

IN order to volatilise the zinc or other metal, the ore is mixed with fuel and fed on to the grate of a blowing hearth, which is in connection with a furnace chamber. The blowing hearth consists of a rectangular trough having a horizontal grate rotatable on hollow trunnions, which latter are cooled by the air blast which passes through them. A vertical wall extends laterally across the furnace behind which the ore to be treated collects and becomes pre-heated. Free passages are left both at the top and bottom of the wall, the upper one permitting the gases and fumes to escape to the flue, while the lower space allows the ore behind the wall to be raked forward on to the grate of the blowing hearth as required.—F. R.

Furnace; Metallurgical —. R. Hübner, New York. U.S. Pat. 934,532, Sept. 21, 1909.

THE furnace consists of a series of horizontal heating flues and ore chambers placed above each other alternately. The heating flues are provided with gas and air burners and with dampers between them and a common flue, for modifying the flow of the products of combustion through the furnace.—J. W. H.

Furnaces for reducing ores. G. Gröndal, Djursholm, Sweden, Assignor to American Gröndal, Kjellin Co., New York. U.S. Pat. 936,124, Oct. 5, 1909.

THE furnace consists of two or more parallel tubular furnaces, through which the ore is conveyed, and a series of regenerative chambers. The entrance ends of the furnaces are connected with a gas main and with a supply of air under pressure. Means are provided for controlling the flow of gas and air to and from the regenerative chambers.—F. R.

Furnace for smelting ores. W. Kemp, Tucson, Ariz., Assignor to the Kemp Hydro-Carbon Furnace Co., New York. U.S. Pat. 936,781, Oct. 12, 1909.

THE furnace consists of a flat-bottomed smelting chamber, having water-jacketed walls which extend laterally inwards at the top and from which rises a water-jacketed charging shaft of smaller diameter. The chamber is provided with openings inclined inwards and downwards, into which burners project. The walls of the smelting chamber slope outwards and decrease in thickness from the bottom upwards to the burner apertures.—F. R.

Charges of smelting furnaces and the like; Means for calculating the amount of constituents of the —. R. Marshall, London, Eng. Pat. 23,981, Nov. 9, 1908.

THE claim is for a circular slide rule for calculating furnace charges.—O. F. H.

Copper; Process for obtaining cement —. O. Fröhlich, Berlin, Eng. Pat. 27,025, Dec. 12, 1908. Under Int. Conv., Jan. 28, 1908.

IN the precipitation of copper from solutions of its salts by means of metallic iron, it has been almost invariably found impossible to obtain a metal of greater than 90 per cent. purity, and this only by stirring the liquid and raising its temperature to about 60°–90° C. It is now claimed that, if the circulation of the liquid be increased to such a degree that at least the whole of the solution passes round in a second and a half, the metal is precipitated almost free from iron. The necessary circulation may be obtained by means of an endless screw, which revolves within a tube, the whole being placed vertically within the precipitation vat. Using a chloride liquor, and raising the temperature to about 80°–90° C., the time of circulation being one second, it is found that, at 60° C., almost the entire layer of copper falls to the bottom of the vat. Subsequently, no further copper adheres to the iron, with the exception of a thin layer which may contain a

small amount of black iron oxide. The final purification of the precipitated metal is achieved by washing or by a system of magnetic separation.—C. A. W.

Copper; Recovery of — from cuprous residues. D. Crispo, Antwerp, Belgium. U.S. Pat. 936,762, Oct. 12, 1909.

RESIDUES containing metallic copper, are treated with dilute sulphuric acid and manganese dioxide, with the addition of sufficient iron persulphate to act as a contact agent and accelerate the solution of the copper.—F. R.

Coating metals; Apparatus for —. H. M. Huxley, Assignor to American Steel and Wire Co., Worcester, Mass. U.S. Pat. 928,385, July 20, 1909.

WHERE a large body of metal has to be maintained in the molten condition, such as in the galvanising of wire, sheets, etc., in place of the iron vessels commonly used, which are acted upon by the zinc, resulting in contamination of the metal besides damage to the vessel, graphite or plumbago vessels are employed, but as these are affected by direct exposure to the fire, they are floated on a bath of molten lead contained in an iron outer vessel. It is not necessary for the graphite inner vessel to have great strength, as the buoyant nature of the molten lead bath evenly supports the weight of the zinc or other coating metal. To avoid loss from oxidation, the surface of the metal is covered with floating plates of graphite or other material, which is lighter than the metal and unaffected by it.—F. R.

Depositing metals; Process of —. C. H. Zieme, Assignor to G. L. Patterson, W. R. Kinnear, and C. W. Johnson, New Castle, Pa. U.S. Pat. 934,704, Sept. 21, 1909.

THE surfaces to be coated are covered with a fabric containing "carbonising material" loaded with the metal to be deposited in a partially oxidised form, e.g., zinc dust, and then subjected to heat sufficient "to carbonise the carbonising material and deposit the metal mingled therewith."—J. W. H.

Sherardising [Coating metals with zinc]; Plant for —. W. C. Robinson, Pittsburg, Pa. U.S. Pat. 935,058, Sept. 28, 1909.

IN a plant for sherardizing, the retort is supported on a pivoted cradle which permits the contents of the retort to be discharged into a pit, where the articles coated are separated from the treating material, the latter being automatically conveyed to the charging bin.—F. R.

Metals; Method of plating —. W. Griffith, Pittsburg, Pa. U.S. Pat. 936,713, Oct. 12, 1909.

THE surface of iron, steel, or other metal, having been cleaned, is given a coating of a convenient alkali solution. This is then covered with one or more layers of a suitable alloy of lower fusing point, when, finally, a metal that will unite with the last-named alloy is applied in a molten condition.—C. A. W.

Antifriction alloy. E. A. Touceda, Albany, N.Y. U.S. Pat. 934,637, Sept. 21, 1909.

THE alloy consists of a relatively large proportion of cadmium and a relatively small proportion of magnesium. It is stated to be hardened and toughened by the magnesium which forms substantially 3½ per cent. of the whole.—J. W. H.

[Copper-titanium] alloy, and process for its production. A. J. Rossi, Assignor to Titanium Alloy Manufacturing Co., New York. U.S. Pat. 935,863, Oct. 5, 1909.

ALLOYS are produced by melting copper, or an alloy of copper and titanium, with another metal previously alloyed with titanium or mechanically mixed with it.—F. R.

Metal; Composite —. J. G. Mellen, New York. U.S. Pat. 936,339, Oct. 12, 1909.

THE alloy is composed of aluminium, magnesium, and phosphor-copper. A metal of the composition: alu-

minium, 79 parts; magnesium, 11; copper, 9.998; phosphorus, 0.002 part is instanced, and is stated to be characterised by great lightness, hardness, and strength.

—C. A. W.

Alloys of high magnesium content; Employment of — in the manufacture of ordinary industrial articles. Chem. Fabr. Griesheim-Elektron. Fr. Pat. 401,648, April 3, 1909.

THE claim relates to the production of alloys, containing high proportions of magnesium in combination with one or more foreign metals, preferably of low specific gravities ranging from 1.75 to 2.2. As an example calcium or aluminium may be employed. The proportion of magnesium is never allowed to exceed 99.5 or to go below 80 per cent. It is stated that, taking into account their low specific gravities, these alloys possess unusually high degrees of resistance, ductility, and malleability. The tendency to oxidise in air, moreover, is not much greater than that of copper or tin, the thin film of oxide produced forming a protective coating over the surface of the alloy.

—C. A. W.

Alloy of copper, zinc, tin, and mercury. P. M. Séguay. Fr. Pat. 401,750, Aug. 7, 1908.

THE metals copper, zinc, and tin are melted in the same crucible in the order given, a certain quantity of the zinc being held back. Complete fusion having been attained, the requisite amount of mercury is amalgamated with the residual zinc, weighted with moistened graphite and dropped into the bath. The bath being stirred energetically, the coating of graphite falls off, when the mercury ascends from the bottom and is said to become perfectly incorporated. The alloy: copper, 75 parts; zinc, 31.5; tin, 5; and mercury, 3 parts, is instanced and is stated to be of considerable tenacity and to be readily workable in the lathe.—C. A. W.

Zinc; Process of treating —. S. Frank, Frankfort-on-the-Maine, Germany. U.S. Pat. 935,900, Oct. 5, 1909.

METALLIC zinc is produced having the physical properties of brass and with a fine crystalline structure, by causing it to flow at a temperature between 30° and 80° C., through the aperture of a die, on being subjected to a pressure of not less than 6000 kilos. per sq. cm. (85,320 lb. per sq. in.).

—P. R.

Zinc ores; Continuous treatment of — by the method of precipitation, using cast iron as reacting metal. Imbert Process Co. Fr. Pat. 401,667, Aug. 3, 1908.

THE pulverised zinc blende, or analogous ore, mixed with the necessary fluxes, is continuously brought into contact with a stream of molten iron. The reaction is carried on in an apparatus which may be caused to oscillate slowly and which comprises two or more chambers, one of which is arranged as a gas furnace of the Siemens-Martin type. In this last the cast iron is melted and at the same time superheated to a degree some way above the fusion point. The fusion chamber communicates, through the partition, with one or more reaction chambers, by channels lying along the floor below the level of the molten iron. The procedure is as follows: the iron having been superheated to the requisite temperature, the apparatus is given the necessary inclination so that the molten metal flows into the reaction chamber, where it comes into contact with the ore mixture introduced at the same time in either a solid or molten condition. The heat necessary for the ensuing reaction is supplied by the molten iron, the zinc produced being conveyed to condensers through flues which, to prevent premature condensation, are built in the separating partitions. The iron sulphides and slags which are formed at the same time float on the surface of the metal and gradually pass away through an overflow, being finally removed from the chamber through a siphon. In this way contact of the metal with the exterior atmosphere is avoided. The reaction having been completed, the apparatus is inclined in the opposite direction so that the molten iron flows back into the fusion chamber, where it recovers the heat lost in the preceding operations. Subsequently, the procedure is repeated as before. In order

to avoid as far as possible losses of heat by radiation, the waste gases from the furnace may be made to pass round the reaction chamber and condenser flues.—C. A. W.

[On reduction] Metallurgical process. O. B. Dawson, El Paso, Tex., Assignor to American Reduction and Refining Co., New York. U.S. Pat. 936,095, Oct. 5, 1909.

ORES of metals, which do not form carbides, are heated to incandescence but not to such a temperature as to cause fusion or volatilisation, and the contained metal reduced by means of water-gas or carbon monoxide in the absence of air and flux. After the metal has been reduced, granular carbon is introduced and the temperature raised to the melting point of the metal.—F. R.

Ore; Process for smelting —. J. P. Welch, Assignor to J. J. Sinder, Salt Lake City, Utah. U.S. Pat. 937,031, Oct. 12, 1909.

THE ore, in a constantly falling and flowing mass, is brought into contact with fused silica, or similar mineral, in a revolving furnace. At the same time the whole is subjected to the heat of an impinging stream of burning carbon, or hydrocarbon, with an excess of oxygen. The ore should have been previously calcined and may itself be employed, in the reaction, in a molten condition.—C. A. W.

Slags; Process of deacidising —. O. Thallner, Assignor to the Firm of Bismarckhütte, Bismarckhütte, Germany. U.S. Pat. 936,382, Oct. 12, 1909.

AN excess of metallic aluminium is forced under the surface of a bath of molten steel, so that when the steel has been completely deoxidised, free aluminium will rise to the surface and act on the ferruginous slag from below.—F. R.

Precious metals; Process of extracting — from ores. J. Kitzee, Philadelphia, Pa. U.S. Pat. 936,545, Oct. 12, 1909.

THE ore is subjected to the solvent action of a chlorinated water which may, for example, be the anodic product arising from the electrolysis of a chloride. The resulting solution is afterwards brought into contact with a gaseous compound of nitrogen, produced with the aid of the electric arc. The process may be simplified by previously saturating the preliminary chlorine solution with the gaseous product, containing an unstable oxide of nitrogen, obtained as above.—C. A. W.

Ores; Process of amalgamating and separating of metallic —. R. Luckenbach, Colwyn, Pa., Assignor to Berindum Extraction Co., Arizona. U.S. Pat. 937,033, Oct. 12, 1909.

THE pulverised ore is projected by streams of liquid over a series of electrified bodies of mercury, held on a number of trays supported within the apparatus alternately on opposite sides, so that the fluid takes a tortuous course as it passes down the vessel. The channels running from floor to floor are given a rounded form, by hollowing the sides of the apparatus at these points. The mercury then is supported on those portions of the path to which the heavier material is projected by the centrifugal force developed at each turn. The lighter material, not falling on the mercury surfaces, is swept away by streams of liquid projected into each chamber, the movement being facilitated by the slight downward inclination given to each floor.—C. A. W.

Metals; Extraction of — from their ores. C. A. Stevens. Fr. Pat. 401,443, March 31, 1909.

THE general principle of the method is, briefly, to smelt an intimate mixture of the ore with an alkali or an alkaline-earth in conjunction with some carboniferous material. The apparatus consists of a long narrow vertical chamber provided at the top with a hopper, which can be closed when necessary, and at the bottom with a vat of water, from which it is separated by means of a movable floor. The vessel is provided on its two longest sides with combustion chambers. The products of combustion from

these are passed up the two sides of the reaction chamber and are finally carried away through chimneys situated on the two remaining sides. In this way, the reaction chamber is heated on all sides by the hot gases and a relatively high temperature can be produced within it. During the reaction, water is made to run slowly through the vat, so that the reduced metal, as it condenses in the liquid, gives rise to a cloud of steam which, passing up the furnace, is decomposed into carbon monoxide and hydrogen. In a similar manner there is a great evolution of heat as the water vapour comes into contact with the quicklime produced in the early stages of the reduction. As the temperature rises, the alkali hydroxides and carbonates may even be reduced to metallic potassium and sodium, and these metals will then effect the removal of sulphur, selenium, tellurium, and arsenic from the ore.—C. A. W.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

(A.)—ELECTRO-CHEMISTRY.

Electrical furnaces; Working limit in — due to the "pinch" phenomenon. C. Hering. Trans. Amer. Electrochem. Soc., 1909, 15, 255—277.

Is that class of electric furnaces in which the resistor is a fluid, an effect called the "pinch" phenomenon, noticed by the author two years ago, sets a limit to the increase of current and therefore of temperature available. When a current, either direct or alternating, passes through a liquid conductor, the conductor tends to contract in cross-section. The action is due to electro-magnetic forces, and when high current-densities are used, is sufficient to rupture the circuit. Northrup has explained that it is due to the mutual attraction of the current elements in the conductor, and has examined the phenomenon mathematically. For conductors of circular cross-section he derives the formula:—

$$P = \frac{C^2}{44,479,100S}$$

where P is the pressure in lb. per sq. cm. at the centre of the conductor, acting axially; C is the current in amperes, and S is the cross-section in sq. cm. This attracting force acts on the material itself which carries the current. The phenomenon is not of a simple nature, since unknown quantities such as viscosity, change of density at high temperatures, etc., enter into it. Mechanical obstructions such as floating masses or particles may so constrict the cross-section as to raise the current density to the critical point, bringing about the "pinch" phenomenon. The "pinching" force depends only on the current and the shape and size of the cross-section of the conductor; it is independent of the voltage, resistance, watts, heat, temperature, length of channel, etc., except as these affect the current and cross-section of the conductor. The resistance to "pinching" depends upon the density of the liquid and upon the depth of the axis of the contracted column. The contraction which takes place involves also the viscosity of the liquid, the presence of floating masses, etc. From the Northrup formula it will be seen that there are two levels of the liquid conductor where the hydrostatic and the electro-magnetic pressures are equal. The upper level is a stable one, since, in the event of a slight displacement, the hydrostatic pressure will restore the liquid to its former level. The lower level will be unstable, and a mechanical reduction of level will determine the rupture of the liquid conductor. The rupturing phenomenon takes place at high current-densities, and need not be feared in low current-density furnaces. If rupture does occur, a frozen charge usually results and the furnace must be dismantled, unless by opening the circuit the rupture heals. The critical current determines the maximum temperature that can be reached in a given furnace. It is greater the deeper the channel, the higher the density, the less the viscosity, the smoother and more regular the channel, and the more free the surface is maintained from floating masses.—J. W. H.

Electrode losses; [Electric] furnace —. C. A. Hansen. Trans. Amer. Electrochem. Soc., 1909, 15, 279—293.

The author has investigated the losses in the electrodes of electric furnaces and compared the efficiencies of carbon and graphite electrodes. Usually, to ensure good electrical connections, these electrodes are water-

cooled at the cable contacts. There are two main losses, that due to the flow of heat from the hot to the cold end of the electrode, and that due to electrical conduction, the C²R loss. The heat conductivities of carbon and graphite are as 1 to 18 (Fitzgerald), and their electrical resistances about 3.8 to 1 (Lincoln). From these figures it would be expected that graphite would be the more efficient when the difference between the C²R losses exceeded the difference between the heat conductivity losses. Experiments were made in a resistance furnace for the experimental manufacture of titanium carbide, using electrodes 8 in. by 8 in. cross-section. In another set of tests, when a furnace with a wider end wall and with more carborundum packing, necessitating longer electrodes, was used, no increase in total electrode loss took place—the efficiency had been raised by increasing the length of electrode embedded in the end wall. Other experiments were made in a smaller furnace with idle electrodes in the side walls, using cracked arc lamp carbons as the charge. One of each pair of terminals was a graphite electrode, the other being of carbon. The idle side terminals were used for direct comparison of heat conduction. Knowing the physical changes in some carbons with rise of temperature, data from which the maximum temperature could be determined were obtained. Motor brush carbons were also embedded in the charge for this purpose. Three distinct temperature approximations could be made by measuring: (1) hardness by the Shore scleroscope; (2) electrical resistance; (3) density, by weighing in benzol. The results show that the carbon electrodes were graphitised at the tips in the course of the run, and that the change from carbon to graphite is a gradual one. Carbon is more efficient than graphite for current densities under 200 amps. per sq. in. In furnaces taking 500 kilowatts the electrode losses may amount to 15 per cent. of the total load, and in short furnaces the losses may be greater. The ratio of heat conductivity of graphite and carbon, under the conditions of the tests, is about 8 to 1, the relation 18 to 1 being probably brought down by the partial graphitisation of the carbon.—J. W. H.

Platinum trioxide. Wöhler and Martin. See VII.

PATENTS.

Batteries; Primary —. W. A. F. Bleeck, South Brisbane, Australia. Eng. Pat. 15,194, June 29, 1909.

THE cell consists of a zinc rod in a porous pot, surrounded by a perforated cylinder of carbon in an outer containing vessel. The exciting liquid is a solution of sodium hydroxide with the addition of a little gum arabic, to reduce the rate of diffusion. The depolarising fluid consists approximately of 20 oz. of commercial hydrochloric acid (1 to 3) in which is dissolved 1 oz. of ferrous sulphate or nickel sulphate, or any mixture of the two, and to which 8 oz. of commercial chromic acid are subsequently added. (See also Eng. Pat. 5297 of 1908; this J., 1908, 1025).—F. R.

Storage-battery plates; Process of preparing —. W. Morrison, Assignor to D. P. Perry, Chicago, Ill. U.S. Pat. 935,316, Sept. 28, 1909.

A LEAD plate or grid is filled with paste in any suitable manner, then dried, and afterwards dipped in a solution containing glycerin and sulphuric acid. The plate is again dried, and subsequently treated with a solution containing water, formaldehyde, formic acid and sulphuric acid.—B. N.

Accumulators; Alkaline —. Nya Ackkumulator Aktiebolaget Jungner. Fr. Pat. 401,453, March 31, 1909.

It is found that, in an alkaline accumulator, the expensive positive support of nickel, or nickel alloy, may be readily replaced by one of iron. In fact, it is stated that the active material, provided it be insoluble in the alkaline electrolyte, has the property of rendering the surface of the iron passive so that the metal is rendered inactive

towards an oxidising electrolysis at the anode. The surface of the iron must be well polished and absolutely free from rust; it is found, moreover, that the best results are obtained when the metal has been alloyed with silicon, manganese, chromium, tungsten, or some other analogous element. The active material may consist of three parts of nickelous hydroxide intimately mixed with one part of graphite. In this case, during the subsequent electrolysis, the oxygen evolved will at once produce the necessary protective coating. In the preliminary fixation of the active material around the support it is necessary to employ, as moulding liquid, some non-electrolyte such as paraffin oil. The metallic iron should also receive a coating of the oil, in order to prevent the formation of surface rust.—C. A. W.

Electrode; Iron —. M. Roloff, Hagen, Germany. U.S. Pat. 934,839, Sept. 21, 1909.

THE active material for the negative pole plates of alkaline accumulators consists of magnetic oxide of iron, derived from forge scale by magnetic means, in order to separate it from the non-magnetic ingredients of the scale.—B. N.

Graphite articles (electrodes, etc.) and process of making the same. A. M. Williamson, Assignor to Internat. Acheson Graphite Co., Niagara Falls, N.Y. U.S. Pat. 935,180, Sept. 28, 1909.

THE claim is for a carbon article formed by moulding powdered carbon and a carbonaceous binder, expelling volatile constituents by heat, and impregnating with a material yielding a carbonaceous residue, the whole being then "graphitised." Such articles are said to be less porous and to have a higher electrical conductivity than those prepared from unimpregnated carbons.—F. SONS.

Electrolysis of aqueous solutions; Apparatus for the —. M. Huth, Charlottenburg, Assignor to Siemens und Halske A.-G., Berlin, Germany. U.S. Pat. 935,109, Sept. 28, 1909.

FOR the electrolysis of zinc sulphate solutions, or solutions of other sulphates, the anode consists of massive artificially prepared manganese peroxide, free from constituents susceptible to the action of the electrolyte, and coated with ceresin. The anodes are prepared from a mixture of pure manganese nitrate and a binding agent, the mixture being pressed into moulds and heated.—B. N.

Electrolytic apparatus. J. L. Roberts, New York. U.S. Pat. 936,039, Oct. 5, 1909.

A METHOD of making porous diaphragms is claimed consisting of forming the diaphragm of woody material and then partially carbonising it. The carbonising is carried out by enclosing the article in a rigid holder of the same size and shape and then subjecting it to heat.—J. W. H.

Air and other gases; Apparatus for electrically treating —. J. H. Bridge, Philadelphia, Pa. U.S. Pat. 935,457, Sept. 28, 1909.

THE ozoniser comprises a tubular electrode, enclosed in a second tubular electrode, the former having a number of perforations through which air or other gas may be passed in line streams from one side of the electrode to the other. A number of electric discharges originate around the perforations, so that the gas in passing from one side of the electrode to the other is surrounded by the electric discharges.—B. N.

Electric discharges; Production of — with great energy consumption. Elektrochemische Werke Ges.m.b.H. Addition, dated March 31, 1909, to Fr. Pat. 389,112, April 10, 1908 (this J., 1908, 986).

It has been found that, for the production of voltaic arcs between concentric annular electrodes, it is not necessary to employ the very high pressures, ranging to several thousands of volts, described in the original specification. On the contrary, provided high current intensities of more than fifty amperes are employed, the pressure may be reduced to some hundreds of volts,

the minimum voltage varying, of course, with the distance between the electrodes. It is moreover proposed to modify the system, by giving to the interior electrode the form of a rod arranged perpendicularly to the plane of the annular electrode, and at some distance from it. In this way the arc is obtained in the shape of a cone, while, by the use of a third electrode on the opposite face of the cylindrical furnace, a bi-conical flame is produced. The arrangement of the apparatus is necessarily somewhat modified. Employing a furnace with three electrodes, the air is admitted through tangential tuyères at the ends, while the reaction products are aspirated through openings surrounding the annular electrode in the centre.—C. A. W.

Electric furnace. W. A. Smith, Assignor to the International Acheson Graphite Co., Niagara Falls, N.Y. U.S. Pat. 935,937, Oct. 5, 1909.

THE inner walls of the furnace (of the type used in making carborundum) are made permeable to gases. Movable heat-retaining walls are placed near the permeable walls and by the admission of air into the space between them, the gases, given off from the charge under treatment, are burnt.—J. W. H.

Electric-furnace terminal. E. C. Speiden, Assignor to the International Acheson Graphite Co., Niagara Falls, N.Y. U.S. Pat. 935,939, Oct. 5, 1909.

THE terminal is built up of strips or rods of graphite and a filling of granular electrically conductive material (subdivided graphite) of low heat conductivity. The length of the strips of graphite is in the direction of the current flow and one or more of the strips are divided transversely.—J. W. H.

Platinum; The electrolytic deposition of ——. W. J. McCaughey. Trans. Amer. Electrochem. Soc., 1909, 15, 523—527.

IN order to ensure an adherent deposit of platinum it was found essential that the metal upon which the deposition takes place, should have no tendency to dissolve in the electrolyte. For the preparation of platinum-plated bottles, the bottles were first coated with gold by means of an alkaline cyanide solution. The deposit, though soft, was adherent and formed an excellent basis for building up a harder deposit of platinum. Using a hot solution of potassium chloroplatinate the electrolyte near the cathode became alkaline and a

dark cloud of finely-divided platinum formed. By rotating the cathode or by stirring the electrolyte, the formation of a cloud was delayed and a firmer deposit obtained. Experiments were made with other electrolytes. The deposit from cyanide solutions was very good, but after a time the formation of complex cyanides prevented further deposition. A satisfactory electrolyte was made by adding 10 grms. of citric acid and 2 grms. of potassium chloroplatinate to 100 c.c. of water. By continued use, the solution lost its efficiency; the addition of a little hydrochloric acid restored the solution by neutralising the liberated alkali. By substituting for potassium chloroplatinate ammonium platonic chloride, the addition of hydrochloric acid was found to be unnecessary. With low current density, bright non-adherent coatings were obtained, while high current density gave hard steely deposits. Uneven current distribution produced both kinds of deposits. Satisfactory deposits were obtained at a current density of 1 ampère per sq. ft. for the bottles and 1.8 amps. per sq. ft. for the covers, but to prevent hard crusty deposits the covers were placed in the bath for a very short time, about one minute, a thick deposit being obtained by successive treatments with fresh solutions.—J. W. H.

PATENTS.

Magnesium; Production of ——. F. von Kügelgen, Holcombs Rock, Va., and G. O. Seward, East Orange, N.J., Assignors to the Virginia Laboratory Co., New York. U.S. Pat. 935,796, Oct. 5, 1909.

By electrolysis of a magnesium salt, such as fused magnesium chloride, using a less electro-positive metal, such as aluminium, as the cathode, an alloy of magnesium is obtained. In a second operation, by using this alloy as the anode with a suitable molten electrolyte, the magnesium is dissolved out of the alloy and deposited at the cathode.—J. W. H.

Electroplating objects; Mechanical arrangement for ——. W. Pfannhauser, Leipzig, Germany. U.S. Pat. 936,472, Oct. 12, 1909.

THE material to be coated with metal is drawn, by means of several pairs of small rollers connected to one pole of the electric circuit, between larger pairs of rollers, disposed alternately with respect to the pairs of small rollers, and on to which the electrolyte is delivered. The electrolyte collects in a trough below, in which the lower rollers rotate, so that the liquid is applied to both sides of the material. The larger rollers are connected to the other pole of the circuit.—B. N.

Films or flakes [electrolytically]; Process of making metallic ——. T. A. Edison, Llewellyn Park, Orange, N.J., Assignor to Edison Storage Battery Co., West Orange, N.J. U.S. Pat. 936,525, Oct. 12, 1909.

FILMS or flakes of cobalt, nickel, or cobalt-nickel are prepared by electrolytically depositing a layer or film of a soluble metal, such as copper, on a suitable cathode, and afterwards depositing on the film the cobalt, nickel, or cobalt-nickel; or the soluble metal and the cobalt or nickel may be deposited in successive and alternating layers. The composite sheet is separated from the cathode, cut up into bodies of the shape and size desired, and the copper finally dissolved in order to free the flakes of the other metal.—B. N.

XII.—FATTY OILS, FATS, WAXES, AND SOAPS.

Nuts yielding Borneo tallow. C. Beadle and H. P. Stevens. Chem. News, 1909, 100, 173.

BORNEO tallow can be extracted from the nuts of the following plants:—*Shorea stenoptera*, *S. aptera*, *Hopsea aspera*, *Isopsea borneensis*, *S. compressa*, *S. gysbertiana*, *S. Scapherrima*, *S. Martiniana*, and *S. fulcifera*. Samples of the nuts of three of these plants from Kew Gardens contained the following amounts of fat:—*Isopsea borneensis*, 58.0; *S. stenoptera*, 64.6; and *S. aptera*, 49.9 per cent., whilst the quantities yielded by them on expression were 48 to 52, 55 to 60, and 41 to 45 per cent., respectively. The pressed residues had the following approximate composition:—Moisture, 10; fat, 10; albuminoids, 10—18; ash, 2; indigestible matter, 10—27; and carbohydrates (by difference) 27 to 58 per cent. A specimen of Borneo tallow extracted from the nuts of *S. gysbertiana* gave analytical values in close agreement with those found by Lewkowitsch. It is stated that 2500 tons of Borneo tallow were exported from Sarawak during the first nine months of 1908, and that with systematic treatment, 10 times the quantity now collected could be obtained.—C. A. M.

Hare seeds (Gynandropsis pentaphylla); [Oil from —.] D. Hooper. Ann. Rept. Indian Museum, Industrial Section 1908-9, 10.

THESE seeds, of a common plant, yield to ether about 25 per cent. of a thick greenish, drying oil, having an acid value of 6.4; saponification value, 194.6, and iodine value, 119.5.—E. W. L.

Litsae zeylanica; Fat from seeds of —. D. Hooper. Ann. Rept. Indian Museum, Industrial Section, 1908-9, 10.

THE tree grows on the Nilgiri Hills, S. India. The seeds yield 61 per cent. of a cream-coloured fat melting at 40° C., and having sp. gr. (at 40° C.), 0.9317; acid value, 10.0; saponification value, 244.7; iodine value, 46.5; fatty acids, 91.3 per cent.; m.pt. of fatty acids 40° C. The fatty acids consists largely of lauric acid and would be useful if obtainable in sufficient quantity. Oil from other species of *Litsae* is said to be used for candle-making in China and Java.—E. W. L.

Oils; Animal — from India. D. Hooper. Ann. Rept. Indian Museum, Industrial Section, 1908-9, 10—11.

(1). *Gangetic dolphin (Platanista gangetica) oil*—Susu or Sehu—used locally as an embrocation and illuminant, has the following characteristics:—sp. gr. (15° C.), 0.921; acid value, 21.36; saponification value, 198.8; iodine value, 106.9; Reichert-Meissl value, 0.71; fatty acids, 94.0 per cent.; fatty acids: m.pt. 25.5° C.; acid value, 205; iodine value, 116.5. The solid fats consist chiefly of palmitin; no spermaceti is present.

(2). *Fish liver-oils.*—(1). White sting ray (*Trigon microps*); (2). Saw-fish (*Cristis perotteti*); (3). Spotted shark (*Stegostoma tigrinum*); (4). *Rhamphobatis ancylotomus*. The characteristics of these oils are given in the following table:—

	1.	2.	3.	4.
Sp. gr. at 40° C.	0.914	0.900	0.910	0.909
M. pt.	22° C.	27° C.	26.5° C.	25.5° C.
Acid value	0.98	1.0	1.16	1.13
Saponification value	194.0	187.1	185.4	187.4
Iodine value	124.7	92.9	123.2	118.5
Reichert-Meissl value	0.26	0.28	0.21	0.23
Fatty acids, per cent. ...	93.2	94.7	94.2	94.6
M. pt. of fatty acids	37.5° C.	39° C.	39° C.	39° C.
Acid value of fatty acids	203.4	192.2	189.9	190.4

—E. W. L.

Sulphoricinoleic acid and its derivatives. A. Grün and H. Wetterkamp. Z. Farben-Ind., 1909, 8, 279—282.

THE authors' recent experiments on the hydrolytic decomposition of sulphoricinoleic acid confirm their previous conclusions (this J., 1908, 1212). The acid ester, $C_{17}H_{32}(OH)COOC_{17}H_{32}COOH$, which is produced in the first stage of the decomposition, undergoes intramolecular condensation on continuing to heat the aqueous solution, and forms a neutral ester, the lactide of ricinoleic acid. The acid ester, ricinoleic ricinoleate,

was prepared by heating an aqueous solution of sulphoricinoleic acid for 15 hours on the water-bath, extracting the liquid with ether, evaporating the ethereal extract, and drying the residue. It was a yellow, very fluid oil, with a pleasant odour. It was only soluble with difficulty in water, and was also less soluble in alcohol than ricinoleic acid and its sulphonated derivative. When saponified with alcoholic potassium hydroxide solution, it yielded pure potassium ricinoleate. Hence the transformation of sulphoricinoleic acid into ricinoleic ricinoleate takes place without the formation of by-products. The further condensation of this compound into the lactide of ricinoleic acid was not quantitative, even after several hours' boiling. The product consisted of a mixture of the neutral and the acid esters in the proportion of about 2:1. The neutral compound was separated by precipitation with absolute alcohol from an ethereal solution, and purified by repeating this treatment several times. When dried over phosphorus pentoxide it was a neutral, transparent, very viscous fluid, of a yellowish-brown colour. The following constitutional formula is given for it:—

The hydrolytic decomposition of sulphoricinoleic acid followed an analogous course. Hydroxystearic acids give similar condensation products. Sulphodihydroxystearic acid, $C_{18}H_{32}S_2O_{10}$, was prepared by treating dihydroxystearic acid (m. pt. 70° C.) with chlorosulphonic acid. It was a light yellow liquid, which was soluble in organic solvents, and in water, yielding a clear solution. On heating this aqueous solution the sulphuric acid was split off, also with the formation of an acid ester, and finally of the neutral lactide of dihydroxystearic acid. This formation of an anhydride also occurred on simply heating dihydroxystearic acid, the substance first changing to a caoutchouc-like mass and then becoming viscous. Trihydroxystearic acid (m. pt. 110° C.), which is obtained by oxidising ricinoleic acid with potassium permanganate, forms a brown viscous sulphonated derivative.

$CH_3\cdot (CH_2)_5\cdot CH(OSO_3H)\cdot CH_2\cdot (CHOSO_3H)_2\cdot (CH_2)_7\cdot COOH$, on treatment with chlorosulphonic acid. When freshly prepared this compound is soluble in water. On heating the solution, the sulphuric acid is split off quantitatively, whilst the organic components interact to form a fluid product, apparently by condensation of the three trihydroxystearic acid mols. as in the equation:—

Analogous compounds have been found by Bougault and Bourdier (this J., 1909, 29, 802) in conifer waxes.—C. A. M.

XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, &c.

(A.)—PIGMENTS, PAINTS.

Paint tests. U.S. Geological Survey Report.

INVESTIGATIONS in regard to protective coatings for structural materials have recently been made on an extensive scale in different parts of the United States, mostly with co-operation of the American Society for Testing Materials. Severe outdoor tests have been carried out by the Paint Manufacturers' Association at Atlantic City, N.J., where fences, coated with different paints, were exposed for one year to moist sea air, to sudden and considerable changes of temperature, and to the abrasive action of wind-blown sand. Of the "prime" white pigments, white lead (basic carbonate) when used alone showed good colour and covering power, but weathered badly, dusting-off and checking being very noticeable; when used, in large proportions, in appropriate combination with other pigments, however, it gave excellent results. Sublimed white lead (basic sulphate) showed good colour, gloss, and covering power, but some checking and considerable dusting-off took place. Zinc oxide showed fair to good covering power, good colour and gloss, but checking was noticeable. Zinc-lead white showed good colour and gloss, and fair covering power, but dusting-off occurred. With respect to "inert pigments," such as gypsum, whiting, barytes, *blanc fixe*, asbestos (magnesium silicate) and silica, it was found that their use, in moderate quantities, is necessary for the production of a satisfactory mixed paint. Special care is needed in the use of gypsum, owing to its solubility and tendency to leach through the coating of dried linseed oil. Mixed white paints containing large proportions of lithopone failed completely under the severe conditions described above. Paints tinted yellow or gray by addition of ochre, umber, bone-black, lamp-

black, or Venetian red to white paints, showed less checking and dusting-off than the corresponding white paints. With regard to colours, Para red gave better results on a lithopone or white lead base, especially on the latter, than on a base of sublimed white lead or zinc white. Of the blues, the best results were obtained with those on a base of sublimed white lead or zinc white, whilst those on a white lead base failed completely. Chrome green gave good results in the tests, but bronze green faded somewhat and "mildewed" in places, probably owing to separation of carbon. The general conclusion drawn from the Atlantic City tests is that a mixture containing more than one pigment, either with or without a small percentage of "inert pigments," makes a paint that is far superior to one manufactured from one pigment alone. This is in accord with the view that the voids in a paint film are reduced to a minimum and the imperviousness is increased to a maximum by using three pigments, the particles of which have different average sizes, for the preparation of the paint. (See also this J., 1909, 403—408.) For experiments on paints for the protection of iron and steel, see Cushman, this J., 1909, 605.—A. S.

PATENT.

Grinding colours; Machine for —. E. Richter. Ger. Pat. 211,968, April 22, 1908.

THE machine is constructed with the view of permitting the wet grinding of the colours to be effected immediately after the dry grinding. It has two pairs of rollers arranged one above the other. The bearings of the upper pair of rollers are fixed to a carriage which can be moved sideways in its supporting frame; the upper rollers can thus be disposed immediately above the feed-hopper for the lower pair of rollers, or, if it be desired to pass the ground colours between the upper rollers again, the carriage is moved so that the rollers no longer discharge into the feed-hopper. One of the upper pair of rollers is connected in any suitable manner with the driving shaft of the lower pair of rollers.—A. S.

(B.)—RESINS, VARNISHES.

Hungarian fir resin. Angustin. Ges. deut. Naturforscher und Aerzte, Sept., 1909. Z. angew. Chem., 1909, 22, 1989—1990.

IN certain parts of Hungary resin is collected from the *Picea montana* Schirr., and put on the market wrapped in the bark of the tree. This tree yields a larger quantity of resin than the ordinary spruce, *Picea excelsa*. Owing to unsuitable methods of collection the resin suffers very much in appearance, and the author is endeavouring to introduce more rational processes.—J. F. B.

Turpentine oil; Examination of —. P. Nicolardot and L. Clément. Comptes rend., 1909, 149, 572—574.

TO detect adulterants in turpentine, the authors distil fractionally at a pressure of 18 cm. of mercury, when the whole distillation can be carried out at 50° C. Rosin oil is detected by the increased amount of fixed residue. The separate fractions (5 or 6) are examined polarimetrically; pure turpentines give the same rotation up to the last fraction or the last but one, whilst samples containing rosin oil or petroleum show a continuous variation, the negative rotation of the first portions being diminished by petroleum and increased by rosin oil. The flashing point of the oil is lowered by petroleum spirit and raised by rosin oil, whilst "white petroleum" is without sensible effect on it. The alteration of rotatory power in open vessels in the dark and when exposed to light also affords indications of adulteration. Pure turpentine does not alter in the dark, whilst adulterated samples may do so through differential evaporation of their constituents. In the light, turpentine oxidises and becomes less strongly laevo-rotatory; samples containing rosin oil show this effect more strongly.—J. T. D.

Crude lac. D. Hooper. Ann. Rept. Indian Museum, Industrial Section, 1908-9, 7.

The following values were obtained on analysis of the four more important kinds of crude lac:

Lac.	Source.	Water.	Resins.	Colour- ing.	Residue.	Ash.
		per cent.	per cent.	per cent.	per cent.	per cent.
Kusum	<i>Schleichia trijuga</i>	1.8	85.6	2.5	9.4	1.0
Ficus	<i>Ficus</i>	1.8	83.9	2.6	10.2	1.5
Ber	<i>Zizyphus</i>					
	<i>Jujuba</i>	2.0	82.7	2.4	11.5	1.3
Palas	<i>Butea frondosa</i>	2.4	77.4	4.3	14.1	1.8

Kusum lac contains the largest amount of light-coloured resin and the smallest amount of impurities. The average iodine value was 11.4 per cent. The amount of resin in Keri or refuse lac was found to vary from 55 to 72 per cent. A sample from Burma, obtained in a new process of shellac manufacture, left only 15.5 per cent. of resin.

—E. W. L.

Gum benzoïn; Siamese ——. F. Reinitzer. Ges. deut. Naturforscher und Aerzte, Sept., 1909. Z. angew. Chem., 1909, 22, 1994.

SINCE gum benzoïn first exudes as a milk-white body, it cannot contain ready formed the brown siarésinotannol which Lüdy has described as its principal constituent. Siamese benzoïn in loose tears is quite crystalline; it melts at 59° C., and on heating at 40°–50° C. in the dark, it gradually becomes darker in colour and amorphous, probably owing to an oxidation process. The purified crystals melt at 72–8° C. and are monoclinic and colourless; they also undergo the above-mentioned change on heating. They consist of the benzoate of a resin-alcohol which the author terms *lubanol*. They give a green coloration with ferric chloride and are capable of combining with a further quantity of benzoic acid. Lubanol benzoate gives the Liebermann-Salkowski reaction, also a fine blue coloration on warming with chloral hydrate. Siamese benzoïn also contains the benzoate of a body resembling Lüdy's benzoresinotannol, but containing more oxygen than the latter. This body melts at 279° C., crystallises in large prismatic needles and is dextrorotatory in alcoholic solution: the author calls it *siarésinol*. Siarésinol gives a sodium salt sparingly soluble in water, and crystallising in long needles from alcohol. Siarésinol is not oxidised on heating at 40°–50° C.; it gives no coloration with ferric chloride, but it gives the Liebermann-Salkowski reaction. Lastly, Siamese benzoïn contains an amorphous benzoate, which turns reddish at the ordinary temperature, and which can be separated into two different bodies by means of carbon bisulphide. When heated at 100° C. in alkaline solution for a long time it is converted into Lüdy's siarésinotannol. Sumatra benzoïn likewise exudes originally with a white colour, and the sumatresinotannol must be regarded as a secondary oxidation product. Gum benzoïn is only produced under the stimulus of a wound in the tree, and cannot be a product of the bark; it must be regarded as a pathological product of the injured protoplasm, and the theory which derives its origin from tannin is untenable.—J. F. B.

PATENTS.

Gums, gum-resins, resins, and balsams; Process for the complete purification or refinement of —, and compositions produced therefrom. H. W. Johnson, Stockport. Eng. Pats. 20,529, Sept. 30, 1908, and 6917, March 23, 1909.

Two or more of the gums, resins, etc., are mixed together in the raw condition in the proportion desired, and the mixture heated *in vacuo* (preferably after admixture with a solvent such as alcohol) at a temperature sufficient to volatilise all volatile impurities (and the solvent). The expulsion of impurities is accelerated by making the vacuum intermittent, or by mechanical agitation. The

purified residue may be mixed with a suitable oil and used in the manufacture of cement, varnish, paints, etc. Special claim is made for a cement for sealing bottles, etc., which is prepared in this way from a mixture of gum sandarach (7 parts), and Canada or Oregon balsam (3 to 4 parts), subsequently incorporated with castor or other vegetable oil or with a mineral oil (3 parts). An addition of gum mastic or other gum or resin (3 parts) may be made to the original mixture to vary the physical properties of the finished composition. It is stated that a solution of such a preparation in a suitable spirit gives a lacquer, which, applied to outside work, will stand boiling water and is not affected by weather.—C. A. M.

Resinous matter; Process of recovering — [from fibrous vegetable material]. W. J. Hough, Toledo, Ohio. U.S. Pat. 931,608, Aug. 17, 1909.

FIBROUS vegetable material is treated according to the ordinary processes for the manufacture of wood-pulp, such as by heating it with an alkali solution. The liquid portion is then separated from the cellulose and the resins which precipitate from the solution are separated in turn. These resins may be used directly as a soap or they may be treated with an acid to liberate the resin. The alkaline liquid, after the separation of the resins, may be evaporated and subjected to destructive distillation; this operation furnishes gaseous products which may be utilised for heating purposes, and an oil which is useful as a wood preservative, whilst the alkali remains in the still and may be recovered for further use.—W. P. S.

Fats; Rapid method of drying — by oxidation and resinification by means of a current of ozone or ozonised air. Soc. Anon. des Plaques, Pellicules et Papiers Photographiques J. Jouglu. Fr. Pat. 401,747, Aug. 7, 1908.

SURFACES that have been painted, varnished, or treated with printing ink are submitted to the action of ozone mixed with air in proportions varying with the nature of the oil in the paint, varnish, etc.—C. A. M.

(C.)—INDIA-RUBBER, &c.

Latex of Kickxia elastica. E. Fickendey. Tropenpflanzer, 1909, No. 5. Gummi-Zeit., 1909, 24, 12–14. (See also this J., 1909, 945.)

LATEX taken from the trees in the dry season (January and February) showed a faintly acid reaction, had a sp. gr. of 0.979 to 0.988 at 25° C., and gave the following results on analysis:—Water, 47.68; minerals (ash), 0.99; precipitated by lead acetate, 1.98; peptones, 3.25; rubber, 40.72; and resins, 4.46 per cent. Proteins, albumoses, starch, sugar and oxydase were not present. The ash was faintly alkaline and contained:—Alumina, traces; lime, 4.20; magnesia, 39.41; sulphuric anhydride, 17.02; chlorine, 5.42, and phosphoric anhydride, 5.67 per cent.; a little alkali and carbon dioxide were also present. The size of the *Kickxia* latex globules, in comparison with those of other latices, is shown by the following figures:—*Castilleja elastica*, 2 μ to 3 μ ; *Ficus elastica*, 2 μ to 3 μ ; *Sapium spec.* (?), 0.5 μ to 4 μ , but generally 2 μ to 3 μ ; *Hevea brasiliensis*, 0.5 μ to 1 μ or 2 μ ; *Kickxia elastica*, 0.5 μ to 1 μ , also below 0.5 μ . The small size of the globules is one reason for the difficulty experienced in coagulating *Kickxia* latex. A second reason is found by the author in the presence of peptones in the latex. These act as inhibiting colloids, and when peptone-precipitants are added to the latex, coagulation is brought about. The processes available for coagulating *Kickxia* latex are:—(1) *Heating*: this results in a loss of about 8 per cent. of the rubber present, and the product contains lacunæ filled with liquid; (2) *Smoking*: this gives a rubber of good properties, though containing all the impurities of the latex; (3) *Addition of chemical reagents*: peptone precipitants. In practice a freshly-prepared solution of metaphosphoric acid would probably be most convenient. (4) "*Dialysis*" in porous earthenware vessels. Only applicable in the cases of latices which do not contain protective colloids. (3) and (4) are at present only laboratory methods.—E. W. L.

Raw rubber; Origin of "tackiness" in —. F. Frank. Gummi-Zeit., 1909, 24, 39—40. (Cf. Spence, this J., 1909, 374.)

THE author attributes the occurrence of "tackiness" in certain raw rubbers to the presence in the rubber, as coagulated, of imperfectly polymerised portions, which owe their existence to unsatisfactory methods of coagulation. In the smoking process employed in the case of fine Para, every portion of the latex comes under the influence of the coagulating, polymerising agent, and "tackiness" is normally absent. When a mass of raw rubber containing imperfectly polymerised portions is subjected to mechanical working, the faulty portions become distributed through the mass, upon which they exercise a solvent action resulting in general deterioration. The presence of water in the raw rubber tends to check any action of this kind. It is possible that bacterial or enzyme action may play a part in the spread of tackiness, the heat generated either rendering the sound rubber more liable to attack (solution), or even bringing about a direct depolymerisation. The following precautionary measures are advocated:—(1) Intimate mixing of the coagulating agent with the latex. (2) Use of only small quantities of latex at a time, in all cases where the process employed is such as to render likely the formation of lumps and consequent inclusion of uncoagulated latex. (3) Protection of the coagulated rubber from the action of light and heat. (4) Minimum mechanical treatment of the rubber at the place of origin. (5) Packing in cases, and storage in cool places during transport. (6) Presence in the raw rubber of a certain amount of moisture.

—E. W. L.

Assam rubber. D. Hooper. Ann. Rept. Indian Museum, Industrial Section, 1908-9, 6—7.

THE percentage of resin in *Ficus elastica* rubber varies from about 20—30 per cent., in the case of young trees, to less than 10 per cent. in rubber from older trees. The following analyses of rubber from various sources are given:—

Source.	Age of trees.	Water.	Rubber.	Resins.	Protein.	Ash.
	years.	per cent.	per cent.	per cent.	per cent.	per cent.
Harduar	33	0.5	83.0	15.1	1.0	0.4
Government Plantation	33	1.4	85.1	11.5	1.2	0.8
	33	2.8	80.4	13.4	1.4	2.0
ushai	70	0.4	89.1	8.8	0.7	1.0
shutan	—	1.0	83.1	14.2	0.7	1.0
diehmi	100—150	1.3	79.4	16.6	1.2	1.5
Average..	—	1.2	83.4	13.3	1.0	1.1

Other samples of rubber, collected by native agency, are brought into Assam from neighbouring districts. One sample from Bhutan and two from Akha Hills were found to contain, respectively:—90.9, 89.9 and 92.8 per cent. of rubber, and 4.9, 6.5 and 4.9 per cent. of resins. These are, therefore, probably not *F. elastica* rubber.—E. W. L.

Rubber; Determination of — as tetrabromide. T. Budde. Gummi-Zeit., 1909, 24, 4—6.

REPLYING to criticisms by Harries and Kimpel (this J., 1909, 945), of his method for the estimation of rubber in raw and cold-vulcanised samples, the author questions the accuracy of the assumption on which those criticisms are mainly based, viz. that Para rubber, purified by Harries' method (this J., 1905, 448) contains, within very narrow limits, 100 per cent. of pure rubber. It is also pointed out that in a case where raw rubber might be assumed to contain an impurity similar to the hydrocarbon, $C_{10}H_{16}$, found in dammar resin, the properties of this hydrocarbon are such that it could only be separated from the rubber hydrocarbon with extreme difficulty, if at all; the analytical results would not, however, indicate its presence. The author shows, moreover, that the prolonged action of bromine gives rise to high results, which is the direct opposite of what should occur if the more highly

brominated derivatives of rubber are soluble in the mixed solvents employed. From an examination of a number of results the conclusion is drawn that a six hours' bromination gives the most accurate figures. Again the hydrocarbon ($C_{10}H_{16}$) of dammar resin gives, on bromination, products soluble in the mixed solvents of Budde's process, which exhibit a very similar behaviour to that of the soluble body described by Harries and Kimpel (*loc. cit.*). The following revised instructions are given for carrying out the tetrabromide method:—0.15 to 0.2 grm. of the finely-divided sample is covered with 50 c.c. of carbon tetrachloride and allowed to stand for 24 hours. 50 c.c. of the bromine solution (6 c.c. of bromine and 1 grm. of iodine in 1 litre of carbon tetrachloride) are added, and allowed to interact with the swollen or dissolved rubber for 6 hours, with occasional agitation. Half its own volume of alcohol is added to the liquid, which is then vigorously shaken, and allowed to stand overnight. The liquid is poured off through a filter, the residue washed with a mixture of carbon tetrachloride and alcohol (2:1), then with pure alcohol, and finally allowed to remain for 3 to 4 hours in contact with carbon bisulphide. 50 c.c. of benzene (petroleum spirit) are now added, the liquid allowed to clear, and then poured off through the original filter. The precipitate is well washed, in the flask, with alcohol, until all traces of free bromine are removed. The filter and contents are placed in the flask, 25 c.c. of N/5 silver nitrate and 20 c.c. of nitric acid (sp. gr. 1.40) are added, and the flask is covered with a funnel and heated on asbestos wire gauze. When the whole of the rubber bromide is decomposed, the liquid is cooled, and the excess of silver titrated with N/5 ammonium thiocyanate, using ferric ammonium sulphate as indicator. From the amount of silver nitrate used the combined bromine is calculated, and from the latter the rubber, using the factor 0.425,

Rubber articles subject to compression, expansion or torsion; Manufacture of — [from vulcanised waste]. T. Gare, New Brighton. Eng. Pat. 20,302, Sept. 28, 1908.

THE invention consists in the manufacture, by the process described in Eng. Pat. 12,454 of 1906 (this J., 1907, 539), of articles, such as buffers, tyres, valves, springs, etc., which are subject to compression, expansion or torsion. In order to distribute the degree of elasticity of the various portions of the article in accordance with the degree of expansion at each part thereof, layers of powdered vulcanised waste of different quality, or degree of elasticity, are employed. Thus a buffer may be made up of seven horizontal layers, of which the two outer layers and the middle layer may consist of a low quality, with a low degree of elasticity, the two layers adjacent to the middle layer having a greater degree of elasticity, and the two adjacent to the outer layers a still greater degree of elasticity. The qualities may be made to merge gradually one into the other by the employment of mixtures of different qualities of powdered rubber, and the layers may be made to take a wave-like form to prevent creeping.—E. W. L.

Sheet rubber and rubber articles; Manufacture of —. T. Gare, New Brighton. Eng. Pat. 20,303, Sept. 28, 1908.

A KNITTED fabric, used as a base or as an insertion, is coated with a solution of rubber, preferably of the kind described in Eng. Pat. 19,894 of 1906 (this J., 1907, 1288). The surface is then coated with rubber in the form of dust or powder, and the sheet subjected to heat and pressure, preferably in the manner claimed in Eng. Pats. 12,454 of 1906, and 3112 of 1908 (this J., 1907, 534; 1909, 319). Claim is also made for the manufacture of articles from sheet rubber prepared in this way.—C. A. M.

Rubber; Process of reclaiming devulcanised —. E. E. A. G. Meyer, New Brunswick, N.J. U.S. Pat. 936,468, Oct. 12, 1909.

WASTE rubber is "devulcanised" by treating it with a mixture of two solvents, one of which is a rubber solvent

while the other is not, and the product is "depolymerised" by heating it at temperatures above 120° C. with a neutral resinous soap (which may be made from the natural rubber resins) associated or not with an oil which is saponifiable at temperatures above 120°. The process of "depolymerisation" may be conducted under increased pressure. (See also this J., 1909, 375.)—E. W. L.

Elastic composition suitable for filling motor car tyres, &c.
E. C. R. Marks, London. From A. Schaar, Hamburg.
Eng. Pat. 23,264, Oct. 31, 1908.

ONE part by weight of a suitable animal or vegetable colloid such as "tjen-tjen" or Japan glue, is dissolved by heating it with from two to six parts by weight of glycerin. From two to three per cent. of salicylic acid, and about one to two per cent. of tannin are then added to the semi-fluid mass, the resulting mixture being known as the "basic material." Just before use—as, for instance, before charging into a tyre—the basic material is heated to 70–80° C., and from two to twelve per cent. of "lysoform" (a mixture of about equal parts of formaldehyde and soap solution) and 0.25 to 0.5 per cent. of hexamethylenetetramine are incorporated with it. The product on cooling resembles gelatin; it is very soft and its elasticity is permanent. It is not melted by the heat generated in the tyre during running, and does not become crumbly and brittle from the same cause. Still it can be melted and forced into the tyre when freshly made, owing to the fact that only a fraction of the lysoform and of the hexamethylenetetramine have so far come into action. The permanent softness of the material is due more especially to the salicylic acid. The material may be used as an insulator for electricity, heat or sound.—E. W. L.

Washing caoutchouc, gutta-percha, and similar substances; Apparatus for —. F. Kempter, Stuttgart, Germany.
U.S. Pat. 935,849, Oct. 5, 1909, and 936,635, Oct. 12, 1909.

XIV.—TANNING, LEATHER, GLUE, SIZE.

Hides; The interfibrillar substance of animal —. E. H. B. Van Lier. Z. physiol. Chem., 1909, 61, 177–187. Collegium, 1909, 321–328.

THE author has investigated the nature of the compound that is formed by the action of lime upon the "connective" or "binding" tissue of hide, and has experimented with the hides and skins of various animals. The experiments were carried out as follows. Slices of freshly shaved hide were laid one on another and submitted to a pressure of 250 atmospheres for 24 hours, for the removal of blood and tissue-juice. Pieces of the pressed hide weighing about 100 grms. were immersed in 400 c.c. of half-saturated lime water for 1 day, then strained, and immersed in water for 1 day. The alternate extractions with lime-water and water were repeated until an extract was obtained which gave no precipitate with acetic acid. The extracts were strained, and filtered through compressed paper pulp with the aid of the pump. Those obtained at first yielded opalescent filtrates, but in the final stages clear filtrates were obtained. Cattle and horse hides were completely extracted in 8 days, but calf-skins took much longer. Acetic acid was added to the combined filtered extracts, and precipitated a sticky stringy mass soluble in excess of acetic acid. The precipitate was washed with water faintly acidulated with acetic acid, and then dissolved in water, with the addition of sufficient lime-water or caustic soda to give a neutral reaction. It was then reprecipitated with acetic acid, the precipitate collected, washed with aqueous alcohol, alcohol and ether, and dried. The author has named

this substance "coriomucoid" and has compared it with, and found it similar to "tendomucoid," which is prepared in a like manner from animal tendons. He entirely disagrees with the view of Reimer (Ding. Poly. Jour. civ. 143), who stated that "corin" (the name given to his product) was quite different in character and composition from mucin. The author suggests that Reimer's failure to detect any mucous substance was probably due to the fact that he did not work with fresh hide and most likely lost the substance in his long liming process before unhairing. "Coriomucoid," prepared from various hides, contained higher percentages of carbon and nitrogen than "tendomucoid," and exhibited in general the properties of mucin; e.g., (1) after digesting with hydrochloric acid it reduced Fehling's solution; (2) it was soluble in solutions of alkaline earths; (3) it was soluble in excess of acid. While "coriomucoid" is precipitated as a sticky, stringy mass, "tendomucoid" appears as a flocculent precipitate, and the former is more easily precipitated with acid, the latter sometimes requiring the addition of hydrochloric as well as acetic acid for complete precipitation. By the action of sodium hydroxide, the author has isolated a substance, with the properties of glucosylonic acid as described and prepared by Levene (Z. physiol. Chem., 31, 395, 39, 1) from both "tendomucoid" and "coriomucoid," and although the chemical nature of this substance is not thoroughly established, the author considers it proof that "coriomucoid" and "tendomucoid" are very similar substances.—S. H.

Phlobaphenes [reds]; The formation of —. M. Nierenstein and T. A. Webster. Collegium, 1909, 337–341.

AN account is given of experiments on the mechanism of phlobaphene formation from the tannin of mangrove bark. An infusion of the bark was prepared with hot water, clarified by casein, and subjected to the action of air, air free from carbonic acid, oxygen, and air in the presence of hydrogen peroxide. In every case the concentration of tannin decreased as the amount of phlobaphenes increased. The oxidation by means of oxygen yielded a product which was named the β -phlobaphene of mangrove-tannin. Oxidation by potassium persulphate in acetic acid solution and in the presence of sulphuric acid (this J., 1905, 1087) apparently yielded the same product. This phlobaphene, on distillation with zinc dust yielded anthracene. The oxidation with hydrogen peroxide gave a product which was named the α -phlobaphene of mangrove-tannin. This phlobaphene yielded diphenylmethane on distillation with zinc dust, and on digestion with 1 per cent. sulphuric acid yielded the β -phlobaphene. The authors conclude, therefore, that the formation of phlobaphenes is due partly to oxidation and partly to dehydration. They suggest the following type formulae:—

—H. G. B.

Mould on leather; Prevention of —. L. Manstetten. Ledertechn. Rundsch., 1909, 250, 258–259; J. Amer. Leather Chem. Assoc., 1909, 4, 266–267.

CLEANLINESS of walls, floors, vats and supports in the drying and storage rooms is chiefly recommended for preventing mould on leather. To disinfect a storage room, burning sulphur is said to be most suitable, and in obstinate cases sprinkling the floor with dilute hydrofluoric acid. Formalin is said to be comparatively ineffective. A 0.05 per cent. solution of corrosive sublimate is recommended to destroy mould on the hanging poles, cloths, etc.

A 2 per cent. solution of sodium fluoride may be employed with advantage on leather. Salicylic acid in the oil employed will also arrest the evil.—H. G. B.

Extracts; Influence of — on tanning methods. S. C. Hemie, J. Amer. Leather Chem. Assoc., 1909, 4, 260-263.

The author points out that American methods of tanning are in a transition stage in consequence of the growing use of tanning extracts, and also because of the increased employment of myrobalans, valonia, and mangrove-bark. This gradual change has been proceeding for the last twelve years. The use of tanning extracts to any great extent involves a greater strength in tannin and a lower non-tannin content in liquors of any given barkometer strength, when compared with the liquors obtained by leaching oak and hemlock barks. Many tanning extracts also contain quickly penetrating tannins, which are liable to tan the hide before it has been plumped sufficiently by the acids in the liquors. Tanning extracts moreover yield sweeter tan liquors than those obtained from bark. These points must be borne in mind when transforming a bark tannage into an extract tannage.—H. G. B.

Chebulic myrobalans (Terminalia chebula). D. Hoogen, Ann. Rept. Indian Museum, Industrial Section, 1908, 9, 11-12.

Two kinds of nuts, from trees growing in the Poona District, respectively green and brown in colour, were found to possess approximately equal tanning values; the total extract and tannin were, respectively, in the green nuts, 48.1 and 35.0, and in the brown nuts 50.8 and 35.8 per cent. The colour of the fruit is in no sense an indication of its tanning value. Experiments point to the superiority of mature nuts, fallen from the tree in the ordinary course.—E. W. L.

Catechol-tannins. H. Franke, Collegium, 1909, 330-336.

The author points out that solutions of catechol-tannins which impart a yellowish-brown to red-brown colour to leather, are generally stable, with the exception of oak-bark and pine-bark liquors, which contain ellagitannic acid, and form ellagic acid in the tanning process, producing a somewhat brighter colour. It is stated that these "mixed" tannins consist of two parts, (1) a colourless substance easily soluble in cold water, the solution becoming reddish-brown on standing, and (2) a brown or reddish-brown substance, soluble only in hot water and which precipitates on cooling, but in the presence of the first constituent partly remains in solution. This latter substance (phlobaphenes) appears as a sediment in tanning liquors (particularly those of quebracho), and sometimes causes disagreeable patches on the leather. If the colourless oak-bark tannic acid be heated with water at 100° C., a difficultly soluble substance is formed which is identical with the oak-bark phlobaphene, so that it is evident that by oxidation the tannic acid is converted into the phlobaphene. The same effect can also be brought about by bringing the tannin in contact with a current of warm air, and this accounts for the fact that some leathers darken in drying or on exposure to the sun. It is obvious therefore, that to obtain bright coloured liquors, the tanning materials should be extracted with cold water. The author discusses colloidal and colloidal solutions, and points out that, even after repeated filtration, some substance remains suspended in pine or quebracho liquors, giving the appearance of a colloidal solution.—S. H.

Tannin: Action of zinc dust on —. L. F. Iljin, J. prakt. Chem., 1909, 80, 332-336.

GALLOTANNIC ACID (100 grms.) was dissolved in water (1 litre) and boiled with zinc dust (100 grms.) for 15-20 hours. On cooling, a precipitate separated which on acidification and extraction with ether was separated into gallic acid (dissolved in the ether) and a brown syrup. On evaporating in a vacuum the ethyl acetate solution of the latter and subsequent similar treatment with alcohol, an amorphous voluminous powder was obtained. The substance becomes colloidal when dissolved

in water and has the formula, $C_{66}H_{48}O_{31}$, and $[a]_D^{20} = -24.1$ in 95 per cent. alcoholic solution. When heated with dilute sulphuric acid it yields gallic acid.—J. C. C.

Artificial tannin: Composition and constitution of —. P. Biginelli, Gaz. chim. ital., 1909, 39, 11, 268-283.

On boiling an aqueous or alcoholic solution of gallic acid with arsenic acid, carbon dioxide is evolved, and arsenic acid becomes combined, with formation of violet-coloured products. These latter are soluble in water and give precipitates with solutions of alkaloids just as natural tannin does; one or more of them, alone or mixed with unaltered gallic acid, constitute the so-called artificial tannin, or digallic acid, of Schiff. They contain combined arsenic which cannot be completely removed by means of hydrogen sulphide, except after addition of an acid such as hydrochloric acid: when freed from arsenic in this manner, the products no longer have properties similar to those of natural tannin. By using an aqueous solution of gallic acid and heating with arsenic acid only at 80-90° C., combination takes place with practically no liberation of carbon dioxide, and according to the relative proportions of the two acids, one or other (or a mixture) of the two compounds, arsenicogallic acid, $C_6H_2(OH)_2(COOH)O.AsO(OH)_2$, and arsenicodigallic acid, $AsO(OH)_2[(O.C_6H_2(OH)_2COOH)_2]$, is produced. These substances are partially dissociated in aqueous solution (completely in presence of acetic acid or mineral acids) and form addition-compounds with ether and water just as natural tannin does (see this J., 1908, 181). If the solution of gallic acid be boiled with arsenic acid, carbon dioxide is evolved, a portion of the gallic acid being converted into hexahydroxybenzophenone. The latter combines with arsenic acid to form dihexahydroxybenzophenonearsenic acid,

and possibly other compounds. Pyrogallol combines with arsenic acid to give the compound,

These compounds of hexahydroxybenzophenone and pyrogallol with arsenic acid have properties similar to those of the gallic acid compounds and may be classed as artificial tannins. On the other hand, phenol, the dihydroxybenzenes, phloroglucinol, and hydroxyquinol do not form similar compounds with arsenic acid.—A. S.

Tannin: Artificial —. P. Biginelli, Gaz. chim. ital., 1909, 39, 11, 283-289.

The yellow substance prepared by Schiff by the action of phosphorus oxychloride on gallic acid, and called by him artificial tannin or digallic acid, is shown by the author to contain phosphorus and to consist essentially of phosphotrigallic acid, $PO[(O.C_6H_2(OH)_2COOH)_3]$. It has properties similar to those of the compounds of gallic acid with arsenic acid (see preceding abstract). Antimonic acid also combines with gallic acid, hexahydroxybenzophenone, and pyrogallol to form compounds analogous to those furnished by arsenic acid (*loc. cit.*).—A. S.

Skins and hides: Treatment of — for the removal of fat, grease, oil, and lime, and for disinfecting purposes. F. H. E. Lehmann, Eilenburg, Germany. Eng. Pat. 4488, Feb. 23, 1909.

The raw or partly dressed hides or skins are subjected to the action of alternating or continuous electric currents in a bath provided with diaphragms, or the skins are suspended or moved between the electrodes so that they themselves form the diaphragms. For the removal of fat or oil, an alkaline bath is employed, and it is generally possible to remove the hair from the skins thus treated, but in some cases where the skins contain only a small quantity of fat, treatment with lime may be necessary. If lime be used, it is subsequently removed from the skins by subjecting them to the action of an electric current in an alkaline, acid, or neutral bath. Simultaneously with the removal of the fat by the above process, the

skins may undergo a disinfecting process. The chlorides present themselves act as disinfectants, and formaldehyde may be added to the bath.—W. P. S.

XV.—MANURES, &c.

The Fertilisers and Feeding Stuffs (Methods of Analysis) Regulations, 1908. Dated November 9, 1908. Statutory Rules and Orders, 1908. No. 964.

THE Board of Agriculture and Fisheries, in pursuance of the provisions of the Fertilisers and Feeding Stuffs Act, 1906, hereby make the following Regulations:—

1. These Regulations shall take effect on the first day of January, 1909, and remain in force until altered or revoked by the Board of Agriculture and Fisheries.

2. In these Regulations—"The Act" means the Fertilisers and Feeding Stuffs Act, 1906. "Fertiliser" means any article used for fertilising the soil. "Feeding stuff" means any article used as food for cattle (as defined by the Act, *i.e.*, bulls, cows, oxen, heifers, calves, sheep, goats, swine, or horses) or poultry. Other expressions have the same respective meanings as in the Act.

Methods of analysis of fertilisers.

3. The methods of analysis of a fertiliser for the purposes of the Act shall be as follows:—

(i.) *Preparation of the sample for analysis.*—(a) In the case of powdered fertilisers in a dry, or moderately dry, condition, the sample shall be passed through a sieve with perforations about one millimetre in diameter. Adventitious materials which cannot be conveniently crushed, *e.g.*, fragments of metal in basic slag, shall be removed and allowed for. (b) Other substances which are dry enough to powder but which are not in a fine condition shall be pulverised until the sample passes through a sieve with perforations about one millimetre in diameter. (c) Wool, hair, hoof, shoddy, and similar substances, shall be pulled apart and cut until in a fine condition; or, if dry, they may be passed through a shredding machine. (d) Moist fertilisers which do not admit of being passed through a sieve shall be thoroughly mixed by the most suitable means. (e) In the case of horn, shoddy, and other substances which gain or lose water during the process of pulverising, the proportion of water shall be estimated in the coarse and in the powdered condition respectively, and the results of the analysis of the powdered sample shall be calculated to the water content of the original coarse substance. (f) Crystalline or saline materials, such as sulphate of ammonia, nitrate of soda, or potash salts, may be prepared by being well mixed and rapidly ground in a stoneware mortar, the portion finally reserved for analysis being especially finely ground. (g) When the sample has been passed through the sieve and thoroughly mixed, or, if not passed through the sieve, has been thoroughly mixed, not less than 100 grms. shall be placed in a stoppered bottle, and from this the portions for analysis shall be weighed.

(ii.) *Determination of moisture (loss on drying).*—A weighed quantity of the sample shall be dried at 100° C.

(iii.) *Determination of nitrogen.*—The presence or absence of nitrates must first be ascertained. (a) *Nitrogen in absence of nitrates.*—(a) A weighed portion of the sample shall be transferred to a Kjeldahl digestion flask; 10 grms. of potassium sulphate and 25 c.c. of concentrated sulphuric acid shall be added, and the flask heated until a clear liquid, colourless, or of light straw colour, is obtained. A small crystal of copper sulphate or a globule of mercury may be added to the liquid in the digestion flask. (b) The quantity of ammonia shall be determined

by distillation into standard acid after liberation with alkali, and, where mercury has been used, with the addition also of sodium or potassium sulphide solution. (b) *Nitrogen when nitrates are present.*—(a) A weighed portion of the sample shall be transferred to a Kjeldahl digestion flask; 30 c.c. of concentrated sulphuric acid, containing 1 gm. of sulcylic acid, shall be added, and the flask shaken so as to mix its contents without delay. The shaking shall be continued at intervals during ten minutes, the flask being kept cool, and then 5 grms. of sodium thiosulphate and 10 grms. of potassium sulphate shall be added. The flask shall be heated until the contents are colourless or nearly so. Copper sulphate or mercury may be used as described in paragraph (iii.) (a) (a). (b) The quantity of ammonia shall be determined as above prescribed in paragraph (iii.) (a) (b). (c) *Nitrogen in form of ammonium salts.*—A weighed portion of the sample shall be transferred to a distillation flask, and the quantity of ammonia determined as above prescribed in paragraph (iii.) (a) (b). (d) *Nitrogen in nitrates in the absence of ammonium salts and of organic nitrogen.*—One gm. of the sample shall be placed in a half-litre Erlenmeyer flask with 50 c.c. of water. 10 grms. of reduced iron and 20 c.c. of sulphuric acid of 1.35 sp. gr. shall be added. The flask shall be closed with a rubber stopper provided with a thistle tube, the head of which shall be half filled with glass beads. The liquid shall be boiled for five minutes, and the flask shall then be removed from the flame, any liquid that may have accumulated among the beads being rinsed back with water into the flask. The solution shall be boiled for three minutes more, and the beads again washed with a little water. The ammonia shall then be determined as above prescribed in paragraph (iii.) (a) (b). When the proportion of nitrates is small a larger quantity of the sample shall be taken. (e) *Control experiment in determination of nitrogen.*—The materials used in any of the methods described under this paragraph (iii.) shall be determined as to their freedom from nitrogen by means of a control experiment carried out under similar conditions with the same quantities of the reagents which have been employed in the actual analysis, in the case of (a) 1 gm. of pure sugar being used in place of the weighed portion of the sample. The quantity of standard acid used in the control experiment shall be deducted from the total quantity of acid found to have been neutralised in the distillation of the sample.

(iv.) *Determination of phosphates.* (a) *Phosphates soluble in water.*—In the case of superphosphates, dissolved bones, and similar substances, 20 grms. of the sample shall be continuously agitated for 30 minutes in a litre flask with 800 c.c. of water. The flask shall then be filled to the mark, and again shaken, and the contents filtered. 50 c.c. of the filtrate shall be boiled with 20 c.c. of concentrated nitric acid and the phosphoric acid shall be determined by the molybdate method prescribed below in paragraph (iv.) (d). In the case of fertilisers in which the proportion of phosphates soluble in water is small, a larger quantity of the filtrate prepared as above shall be taken. (b) *Phosphates soluble in the prescribed citric acid solution.*—5 grms. of the sample shall be transferred to a stoppered bottle of about 1 litre capacity. 10 grms. of pure crystallised citric acid shall be dissolved in water, the volume shall be made up to 500 c.c., and the solution shall be added to the weighed portion of the sample in the bottle. To lessen the possibility of caking, the portion of the sample in the bottle may be moistened with 5 c.c. of alcohol or methylated spirit before the citric acid solution is added; and in that case the volume of the citric acid solution shall be 495 c.c. instead of 500 c.c. The bottle shall be at once fitted into a mechanical shaking apparatus, and shall be continuously agitated during 30 minutes. The solution shall then be filtered through a large "folded" filter, the whole of the liquid being poured on the paper at once. If not clear, the filtrate shall be again poured through the same paper. 50 c.c. of the filtrate shall be taken and the phosphoric acid shall be determined by the molybdate method prescribed below in paragraph (iv.) (d). (c) *Total phosphoric acid.*—A weighed portion of the sample, in which, if necessary, the organic matter has been destroyed by ignition and the silica removed by appropriate means, shall be dissolved in nitric acid and boiled,

the solution being made up to a definite bulk. The phosphoric acid shall be determined in an aliquot part of the solution by the molybdate method prescribed below in paragraph (iv.) (d). (d) *Molybdate method*.—To the solution, which should preferably contain from 0.1 to 0.2 gm. of phosphoric oxide (P_2O_5), obtained as above described in paragraphs (iv.) (a), (b) or (c), 100 to 150 c.c. of molybdic acid solution prepared as described below, or an excess of such solution, shall be added, and the vessel containing the solution shall be placed in a water bath maintained at $0^\circ C.$ for 15 minutes, or until the solution has reached $0^\circ C.$ It shall then be taken out of the bath and allowed to cool, and the solution filtered, the phospho-molybdate precipitate being washed several times by decantation and finally on the paper with 1 per cent. nitric acid solution. The filtrate and washings shall be mixed with more molybdic acid solution and allowed to stand for some time in a warm place. The phospho-molybdate precipitate shall be dissolved in cold 2 per cent. ammonia solution, prepared as described below, and about 100 c.c. of the ammonia solution shall be used for the solution and washings. 15 to 20 c.c. of magnesia mixture prepared as described below, or an excess of such mixture, shall then be added drop by drop, with constant stirring. After standing at least 2 hours with occasional stirring, the precipitate shall be filtered off, washed with 2 per cent. ammonia solution, dried, and finally weighed as magnesium pyrophosphate. The filtrate and washings shall be tested by the addition of more magnesia mixture. (e) *Preparation of molybdic acid solution*.—125 grms. of molybdic acid and 100 c.c. of water shall be placed in a litre flask, and the molybdic acid shall be dissolved by the addition, while the flask is shaken, of 300 c.c. of 8 per cent. ammonia solution, prepared as described below. 400 grms. of ammonium nitrate shall be added, the solution shall be made up to the mark with water, and the whole added to 1 litre of nitric acid (sp. gr. 1.19). The solution shall be maintained at about $35^\circ C.$ for 24 hours and then filtered. (f) *Preparation of magnesia mixture*.—110 grms. of crystallised magnesium chloride and 140 grms. of ammonium chloride shall be dissolved in 1,300 c.c. of water. This solution shall be mixed with 700 c.c. of 8 per cent. ammonia solution, and the whole shall be allowed to stand for not less than three days and shall be then filtered. (g) *Preparation of the ammonia solutions*.—The 8 per cent. ammonia solution shall be prepared by mixing one volume of ammonia solution of sp. gr. 0.880 with three volumes of water. This solution shall then be adjusted by the addition of more strong ammonia solution or water as required until the sp. gr. of the solution is 0.967. The 2 per cent. ammonia solution shall be prepared by mixing one volume of 8 per cent. ammonia solution with three volumes of water.

(v.) *Determination of potash*.—(a) *Muriate of potash free from sulphates*.—A weighed portion of the sample about 5 grms. in the case of concentrated muriate of potash or 10 grms. in the case of low-grade muriate) shall be dissolved in water, the solution shall be filtered if necessary and made up to 500 c.c. To 50 c.c. of the solution, placed in a porcelain basin, a few drops of hydrochloric acid shall be added, and also 10 c.c. or 20 c.c. according to whether the portion weighed was 5 grms. or 10 grms.) of a solution of platinum chloride containing 0 grms. of platinum per 100 c.c. After evaporation to a syrupy consistency on a water-bath, the contents of the basin shall be allowed to cool and then treated with alcohol of sp. gr. 0.864, being washed by decantation until the alcohol is colourless. The washings shall be passed through a weighed or counterpoised filter paper, on which the precipitate shall be finally collected, washed with alcohol as above, dried at $100^\circ C.$ and weighed. The precipitate is to be regarded as K_2PtCl_6 . (b) *Salts of potash containing sulphates*.—A weighed portion of the sample (about 5 grms. in the case of concentrated sulphate of potash or 10 grms. in the case of kainit or other low-grade salts) shall be boiled with 20 c.c. of hydrochloric acid and 300 c.c. of water in a half-litre flask. Barium chloride solution shall be cautiously added, drop by drop, to the boiling solution until the sulphuric acid is completely precipitated. Any slight excess of barium shall be removed by the addition of the least possible excess of dilute

sulphuric acid. The liquid (without filtration) shall be cooled and made up to 500 c.c. A portion shall then be filtered, and 50 c.c. of the filtrate shall be treated as in paragraph (v.) (a), 10 c.c. or 20 c.c. of platinum chloride solution, as the case may be, being used. (c) *Potash in guanos and mixed fertilisers*.—Ten grms. of the sample shall be gently ignited in order to char organic matter, if present, and shall then be heated for ten minutes with 10 c.c. of concentrated hydrochloric acid, and finally boiled with 300 c.c. of water. The liquid shall be filtered into a half-litre flask, raised to the boiling point, and a slight excess of powdered barium hydrate shall be added. The contents of the flask shall be cooled, made up to 500 c.c. and filtered. Of the filtrate 250 c.c. shall be treated with ammonia solution and excess of ammonium carbonate, and then, while boiling, with a little powdered ammonium oxalate, cooled, made up to 500 c.c. and filtered. Of the filtrate, 100 c.c. are to be evaporated in a platinum dish, and the residue heated, first in the air-bath and then very gently over a low flame, till all ammonium salts are expelled, the temperature being carefully kept below that of low redness. The residue shall be treated with hot water, filtered if necessary, and the potash shall be determined in the filtrate as in paragraph (v.) (a).

Methods of analysis of feeding stuffs.

4. The methods of analysis of a feeding stuff for the purposes of the Act shall be as follows:—

(i.) *Preparation of the sample*.—(a) If the sample is already in a fine condition, e.g., a meal, it shall be thoroughly mixed, and a portion for the determination of the moisture shall be at once taken. (b) If the sample is not in a fine condition, e.g., a cake, it shall be carefully pulverised until the whole passes through a sieve with perforations from 2 to 3 mm. in diameter. It shall then be thoroughly mixed, and a portion for the determination of the moisture shall be at once taken. (c) From the sample thus prepared, a portion not less than 100 grms. in weight shall be taken and further powdered if necessary and passed through a sieve with perforations of about one mm. in diameter. (d) If the original sample is appreciably damp, or if the operations of pulverisation and mixing are likely to result in loss or gain of moisture, the moisture shall be determined in this portion, as well as in the sample prepared as in paragraph (i.) (b), in order that the results of the analysis may be corrected to correspond with the sample in its original condition as regards moisture. (e) Materials which cannot be conveniently pulverised or passed through a sieve shall be thoroughly mixed and sampled by the most suitable means. (f) The prepared portion of the sample shall be placed in a stoppered bottle and from it the portions for analysis shall be weighed.

(ii.) *Determination of moisture (loss on drying)*.—A weighed quantity of the sample shall be dried at $100^\circ C.$

(iii.) *Determination of oil*.—(a) A weighed quantity of the sample shall be placed in a Soxhlet thimble, which shall then be placed in the Soxhlet extraction tube and extracted with washed, re-distilled ether. At the end of 3 to 4 hours the thimble shall be removed from the Soxhlet tube, dried, and its contents finely ground in a small mortar previously rinsed with ether. The substance shall then be returned to the thimble, the mortar being washed out with ether, and the extraction continued for another hour. After evaporation of the solvent the oil shall be dried at $100^\circ C.$ and weighed. The oil shall be re-dissolved in ether and any undissolved matter shall be weighed and deducted. (b) In the case of samples containing saccharine matter, e.g., sugar meals, the weighed portion in the Soxhlet thimble shall be washed twice with water, and then dried, previous to the extraction.

(iv.) *Determination of albuminoids*.—The percentage of albuminoids shall be ascertained by multiplying the percentage of nitrogen by 6.25. The determination of nitrogen shall be carried out as for fertilisers in absence of nitrates, (iii.) (a), with control as in (iii.) (c).

5. In calculating the results of analyses the atomic weights adopted by the International Committee on Atomic Weights shall be employed.

6. Every certificate which is affected by Regulation

No. 3 of the Fertilisers and Feeding Stuffs (General) Regulations, 1906, and these regulations, and which is dated on or after the first day of January, 1909, shall contain the following words:—"The analysis was made in accordance with the Fertilisers and Feeding Stuffs (Methods of Analysis) Regulations, 1908."

7. These regulations may be cited as the Fertilisers and Feeding Stuffs (Method of Analysis) Regulations, 1908.

PATENTS.

Manure: *Manufacture of* ——. A. M. Johnson and J. Austin, Birmingham. Eng. Pat. 11,924, May 20, 1909.

CLAIM is made for a manure prepared by evaporating horse urine, with or without the addition of sulphuric or other suitable acid, until it is brought to the consistency of a syrup, such that it will solidify on cooling; or, by evaporating to the point at which charring begins. The solid may be broken up and used directly, but it is preferred to add solid ingredients, such as gypsum, charcoal, dry earth, ground bones, superphosphates, or the like, before or after solidification. Raw blood also may be added to the urine, before evaporating. The evaporation is best carried out in a vacuum pan at a low temperature, the times evolved being conducted to a suitable vessel containing acid.—F. SÖRN.

Fertilisers: *Method of making solid* ——. B. F. Halvorsen, Assignor to Norsk Hydro-Elektrisk Kvaestof-aktieselskab, Christiania. U.S. Pat. 936,317, Oct. 12, 1909.

XVI.—SUGAR, STARCH, GUM, &c.

Beets of high potash- and low soda-content. K. Andriik and J. Urban. Z. Zuckerind. Böhm., 1909, 34, 1—5.

PREVIOUS investigations have shown that substitution of soda for part of the potash in the beet leads to a smaller content of sugar in the root. The authors have now examined the effect of a deficiency of soda in the soil on the formation of sugar in the beet. Beet seeds from plants of high sugar content were sown at the end of April in drift sand (from the Elbe) of low soda-content; potassium chloride, superphosphate, and ammonium sulphate were used as manure, and the plants were watered with rain water. Growth was slow at first, but improved later, though the weight of the plant at the time of harvest was moderate. The roots were characterised by the formation of fine rootlets in great abundance, due probably to a deficiency of moisture, since in the sandy soil used, most of the moisture and with it the nutrient material, would accumulate at the bottom of the pot in which the plant was grown. The sugar-content of the roots was high (19.4 and 20.5 per cent.). The ratio of potash to soda in one of the plants was found to be 3.61 to 1, the highest hitherto observed by the authors, though they propose to make further experiments with a view to increasing it. The investigation shows that a high ratio of potash to soda is correlated with a high sugar-content in the beet, which appears to confirm the authors' conjecture that beet of low soda-content is rich in sugar.—L. E.

Beetroot juice: *Industrial fermentation of* ——. Formic aldehyde in plants: beetroots. L. Gentil. Bull. Assoc. Chim. Sucr. et Dist., 1909, 27, 169—179.

THE author has shown that during growth, small quantities of formic aldehyde occur in the leaves, and to a somewhat less extent, in the root of the beet; when the leaves have ripened and turned yellow, the formic aldehyde in this part of the plant almost disappears. At the beginning of the campaign, when the roots are not fully ripe, fermentation is often difficult. Since this trouble is obviated by boiling the juice, it might be supposed that it is due to formic aldehyde. Such is not the case, however, since a medium, prepared by dissolving invert sugar, peptone and

distillery yeast-ash in the liquor obtained by distilling the leaves or root of the beet with dilute sodium carbonate solution, is normally fermented by distillery yeast. The difficulty appears to be chiefly due to incomplete hydrolysis of the sugar. During the first few days of the process of extracting the sugar from the cossettes, the sugar is not subjected to the action of hot dilute acid. The authors show that the sugar in beetroot juice is only slightly hydrolysed when treated with 0.25 per cent. of sulphuric acid at 30° C., whereas, at the boiling temperature, hydrolysis is nearly complete. It is probable that the hydrolysing power of the yeasts employed by distillers is weak and may disappear altogether under the conditions which prevail in the fermentation. It is advisable, therefore, to use hot, acid vinasse instead of water for diffusion and to replace the diffusers made of sheet iron by cast iron diffusers in order to avoid the danger of the acid liquor attacking the metal.—L. E.

Raw cane sugars: *Influence of temperature on the polarisation of* ——. H. W. Wiley and A. H. Bryan. Z. V. deutsch. Zucker-Ind., 1909, 916—922.

THE influence of variations of temperature on the polarisation of raw cane sugars is considerable, owing to the presence of appreciable quantities of invert sugar in the products. According to careful measurements the polarisation of sucrose is diminished by 0.0003° Ventzke per 1 per cent. of sugar for a rise of temperature of 1° C. The polarisation of dextrose is for all practical purposes unaffected by moderate variations of temperature. The polarisation of levulose is profoundly modified, the levo-rotation decreasing as the temperature rises. This decrease amounts to 0.00812° Ventzke per 1 per cent. of levulose for 1° C. rise of temperature. Hence it follows that the influence of the temperature on the polarisation of raw cane sugars depends on the composition of the sugar and that two samples which have the same polarisation at one temperature will not necessarily be identical at another temperature. The authors have investigated the influence of temperature on the direct polarisation of a number of samples of raw cane sugars and have tabulated the results. The solutions were made up at the same temperatures as those at which they were subsequently polarised. The results agreed in most cases with the values calculated from the known composition of the samples, sucrose being determined by Clerget's method and invert sugar by cupric reduction. The influence of a rise of temperature of 1° C. may be calculated by multiplying the percentage of sucrose by — 0.0003 and adding to the product one-half of the invert sugar multiplied by + 0.00812. Any difference between the observed and calculated values may be attributed to the fact that the reducing sugars present do not always consist of equal parts of dextrose and levulose. As a general rule it was found that when the direct polarisation reached 83—84° Ventzke, the readings at higher temperatures were lower than those at lower temperatures, but with polarisations below these values, the readings at higher temperatures were either equal to or higher than those at lower temperatures. The point at which the variation due to levulose compensates that due to the sucrose is, however, not fixed but depends on the general composition of the sample.—J. F. B.

Sugar in fresh or exhausted cossettes: *Determination of* ——. by H. Pellé's aqueous digestion method, using the Sachs-Le Docte procedure with hot digestion. A. Le Docte. Bull. Assoc. Chim. Sucr. et Dist., 1909, 27, 180—190.

THE procedure is substantially the same as the modified Sachs-Le Docte method of hot aqueous digestion recently described by Herzfeld (this J., 1909, 846). The author, however, uses tinned copper beakers. The contrivance used to prevent loss of water by evaporation during heating, consists of a metal rim fitted with a rubber envelope, the whole being placed on the beaker as shown in the figure. The amount of water lost during the digestion is quite negligible. A rectangular water-bath, capable of holding six beakers, is employed; this bath is provided with an outer overflow trough and a gauge. The latter is provided with an upper mark corresponding to the height of the bath, and a lower mark indicating the height

at which the water should stand in order that the bath may be full when the beakers are introduced. The bath is also provided with a cover and the beakers are placed in orifices in the latter. Experiment has shown that digestion for 20–25 minutes at 80° C. without any stirring either before or during heating, suffices for complete diffusion; to insure absolute certainty, the author heats the mixture for 30 minutes. The following method of working renders any attention during digestion quite unnecessary:—The water in the bath is heated to boiling, the cover, with the beakers suspended from it, is then placed on the bath, and the source of heat is removed. With a laboratory temperature of 15°–20° C., the bath cools to about 75°–80° C. in 30 minutes; the conditions requisite to produce this fall of temperature are easily determined by trial. The cover and beakers are then transferred to a double-bottomed refrigerating bath containing cylindrical compartments for the reception of the beakers. The current of cooling water is distributed from the space below the false bottom through each cylinder and overflows from the top of the bath; if the cooling water is at 15° C., the contents of the beakers may be cooled to 17°–18° C. in 7–8 minutes. A similar bath is used for digestion if it is desired to effect the heating with a current of hot water which should be maintained at a temperature of 80°–82° C. After cooling, the beakers are shaken before removing the covers; the contents are then filtered and polarised. The weights of the material employed are (for the German saccharimeter): 26 grms. of fresh cossettes or 61 grms. of exhausted cossettes. The material is digested as above described with 177 c.c. of a mixture of water and basic lead acetate solution (containing 5–6 c.c. of the latter) and a 400 mm. tube is used for the polarisation; in the case of the exhausted cossettes, the reading is divided by 2.—L. E.

Sugar-house products; Influence of the non-sugars on the determination of the dry substance in —. V. Staněk. Z. Zuckerind. Böhm., 1909, 34, 5–20.

In the determination of the amount of dry substance in sugar-house products, the most serious errors are those due to the presence of non-sugar substances. With a view to discovering to what extent the presence of various non-sugar substances vitiates the results of such determinations, the author has made experiments with formate, acetate, butyrate, lactate, and glutamate of sodium, with formate, acetate, lactate, and glutamate of potassium, and with betaine. Solutions of these substances of various, known concentrations were prepared and used for determinations of (1) the degrees Balling of the density at 17.5° C., (2) the percentage of dry substance from the refractive index at 20° C., and (3) the percentage of dry substance by heating the solution, mixed with sand, to 102° C. until the weight was practically constant. The results obtained by the piconometric and refractometric methods differed widely from the actual percentages in many cases. Thus, amounts ranging from 44 per cent. (betaine) to 162 per cent. (sodium formate) of the actual quantity of substance were found from the determination of densities of 5 per cent. solutions; with the refractometric method, amounts ranging from 72 per cent. (potassium formate) to 128 per cent. (sodium glutamate) of the actual quantity of substance were found in 5 per cent. solutions. Of course, in mixtures of non-sugar substances positive and negative errors

would counteract each other more or less. With most of the non-sugar substances, piconometric determinations give high results, whilst with the refractometric method, the reverse is the case. Since, however, the examination of sugar-house products and of the mixtures of non-sugar substances present in molasses waste liquors by the refractometric method, yields lower results than those obtained by the gravimetric method, it must be concluded that such materials contain a considerable quantity of an unknown substance of high refractive index. By both physical methods, higher results are obtained with the sodium salts than with the potassium salts of organic acids. In all cases, contraction, which varies with different non-sugar substances, occurs on dilution; the results appear to indicate also that other changes occur on dilution, perhaps in the specific refraction of the non-sugar substances. The non-sugar substances investigated can be freed from water by drying in an air-oven at 102° C.; betaine is thereby converted into the lactone. Salts of volatile organic acids are slightly dissociated on drying, and yield traces of carbonates. It may be presumed that the behaviour of the non-sugar substances on drying would be affected by the presence of large quantities of sucrose; the author proposes to deal with this subject later.—L. E.

Sucrose and other sugars; New, sensitive reaction for —. E. Pozzi-Escot. Bull. Assoc. Chim. Sucri. et Dist., 1909, 27, 179–180.

One c.c. of a 5 per cent. solution of ammonium molybdate, and 2 c.c. of the solution under examination, are placed in a test-tube and 10–12 c.c. of sulphuric acid are carefully poured down the side of the tube. If the solution contains more than 0.0005 grm. of sucrose, a blue ring appears in less than 20 minutes at the junction of the acid and the aqueous solution. If the coloration does not appear, the upper part of the tube is heated until the liquid just boils but no longer, and in less than 30 minutes the blue ring appears; in this way, 0.00002 grm. of sucrose gives a distinct reaction. The author proposes to show shortly that the reaction may be used to distinguish different sugars.—L. E.

Malt sugar [maltose]; Action of Fehling's solution on —. W. L. Lewis. Amer. Chem. J., 1909, 42, 391–319. (See this J., 1908, 31.)

The mode of procedure was as follows:—Solutions of barium hydroxide (181 grms. of crystallised barium hydroxide in 750 c.c. of water), copper sulphate (95.6 grms. of hydrated salt in 300 c.c.), and maltose (24 grms. of hydrated maltose in 70 c.c.), were heated to boiling. The unfiltered barium hydroxide solution was added slowly, and with shaking, to the copper solution, the hot solution of maltose being similarly added to the mixture. The whole was heated, with occasional shaking, in boiling water for an hour, during which time complete reduction was effected. The quantity of maltose used was just sufficient to reduce practically the whole of the copper under these conditions. The nature and proportions of the products were then determined; the carbon dioxide was determined in independent experiments in which a solution of 46.1 grms. of sodium hydroxide in 400 c.c. of water was substituted for the barium hydroxide solution previously mentioned. A total quantity of 135.8 grms. of anhydrous maltose yielded: carbon dioxide, 10.6; formic acid, 4.74; non-volatile gums consisting chiefly of glucoside-acids, 132.8 grms. On hydrolysis, the latter yielded 47.5 grms. of dextrose and 82.35 grms. of non-volatile acids, including: oxalic acid, 0.35; glycollic acid, 3.92; *D*-mannonic lactone, 30.25; and a new hexonic acid (most probably α -hydroxymethyl-*D*-ribonic acid), 10.5 grms. The nature of the remaining 37 grms. of acids was not established. The proportions of the various acids (especially formic and carbonic acids) differ markedly from those observed by Nef in the case of dextrose, levulose, and mannose respectively (*loc. cit.*), and whilst these hexoses were found to yield large amounts of glyceric and trihydroxybutyric acids, the author has not established, with certainty, the presence of any monobasic acids containing 3 or 4 atoms of carbon

in the products from maltose. It is certain also, that oxidation of maltose by Fehling's solution is not accompanied by any very appreciable hydrolysis into two molecules of dextrose, the main oxidation products being glucosido-monobasic acids. According to the author's experiments, it is extremely probable that only two hexonic acids, *viz.*, *d*-mannonic and α -hydroxymethyl-*d*-ribonic acids, are obtained in the hydrolysis of the glucosido-acids formed by the action of Fehling's solution on maltose. "In that case, both acids must be formed by an asymmetric benzilic acid rearrangement from 1,2-maltosone and 2,3-maltosone respectively." "1,2-*d*-Glucosone which must be the common intermediate product when dextrose, levulose, and *d*-mannose are oxidised by Fehling's solution, gives, on the other hand, by a partial asymmetric benzilic acid rearrangement, mainly *d*-gluconic acid and only small amounts of *d*-mannonic acid" (*ibid.*). The author has made preliminary experiments on the behaviour of barium hydroxide on *d*-maltosone and *d*-glucosone which tend to confirm these conclusions with regard to the formation of hexonic acids from maltose and the hexoses in question, but further work is necessary to obtain decisive results.—L. E.

Siris. D. Hooper. Ann. Rept. Indian Museum, Industrial Section, 1908-9, 16.

Siris or *sirish* is a yellowish powder consisting of the roots of *Eromurus aucherianus*, a plant of the lily family. It has a sweetish taste like that of liquorice root. It possesses the property of forming an adhesive vegetable glue with water, and is employed for moulding into vessels for containing oil. Its composition is as follows:—moisture, 9.75; sugar, etc., 49.50; mucilage, 45.17; albumin, 5.93; fibre, 12.00; and ash, 7.65 per cent.—E. W. L.

Sugar production in 1907-8. Monit. Off. du Commerce, Oct. 14, 1909. [T.R.]

The total sugar production of Europe during the season 1908-9 is estimated at 6,487,000 metric tons, as compared with 6,562,000 tons in 1907-8. This amount is distributed among the various producing countries as follows:—

	1907-8.	1908-9.
	Metric tons.	Metric tons.
France.....	727,712	785,000
Germany.....	2,129,597	2,060,000
Austria-Hungary.....	1,424,657	1,400,000
Russia.....	1,410,000	1,275,000
Belgium.....	232,352	255,000
Holland.....	175,184	212,000
Other countries.....	462,772	500,000
Total.....	6,562,274	6,487,000

Metric ton=2,204.6 lb.

The production of cane and beet sugar in extra-European countries is estimated at 7,765,500 metric tons in 1908-9 as against 7,349,381 tons in 1907-8. Thus the total production of sugar during the 1908-9 season was about 14,252,500 metric tons, as compared with 13,911,655 tons in 1907-8.

PATENTS.

Sugar; Art of making — S. von Grabski, Kruschwitz, Germany. U.S. Pat. 934,965, Sept. 21, 1909.

BETTER chips are dried by means of hot lime-kiln gases, from which mechanical impurities have been removed. The gases are then freed from the moisture absorbed from the chips, and utilised in the carbonatation process.—W. P. S.

Saccharine juices; Process for sulphitating and desulphitating — and its applications to various fermentation industries. E. A. Barbet. Sixth Addition, dated July 18, 1908, to Fr. Pat. 361,869, Oct. 27, 1905 (this J., 1906, 1229; 1907, 109, 708, 1250; 1908, 826, 953).

THE juice is heated, prior to desulphitation, by passage through a coil heated by waste steam; at a certain stage

of its descent through the desulphitating column, the juice passes out through a pipe to another heating coil and thence back to the desulphitating column at a stage lower than that at which it left. The perforated plates of the desulphitating column, and the heating and refrigerating coils, are so constructed that only a small quantity of liquid is under treatment at a given time. The desulphitating column consists of cement (reinforced or not), and is made in one piece or built of rings. The desulphitation is carried out under reduced pressure, the amount of air introduced being controlled by a special mercury regulator. A current of air, sterilised by filtration through cotton wool, is injected into the desulphitated and cooled juice, and the latter subsequently passes to the airating column described in the fourth addition (*loc. cit.*, 1908, 826).—L. E.

Juice boilers for sugar or other industries. H. Degroise. Fr. Pat. 401,492, April 1, 1909.

THE tubes of the tubular heaters are slit longitudinally as shown at, *a, a'*, and the edges of the slits are joined by walls, *c, c'*, so that the tubes are divided into two or three compartments in order to increase the heating surface. The slits do not extend to the ends, *d*, of the tubes which are expanded into the tube plates.—W. H. C.

Diffusion; Process and apparatus for continuous — K. Abraham. Fr. Pat. 401,818, April 7, 1909. Under Int. Conv., April 9, 1908.

THE cosettes previously heated to 70–90° C., *e.g.*, by admixture of hot juice, are carried, *e.g.*, by a screw conveyor in a network casing, to the lower, conical, fixed part of a vertical diffuser. This part of the diffuser is provided with sieves through which the descending juice passes to a chamber or chambers bounded on one side by the sieves. Sufficient space is left between the wall of the diffuser and the sieves for the cosettes to pass into the upper part of the diffuser which is kept slowly rotating. As the cosettes ascend, they slowly acquire the rotatory motion and become uniformly distributed. Water (preferably heated to 50° C.) is introduced at the top of the diffuser in quantity nearly sufficient to fill the latter. The juice is drawn off from the above-mentioned chambers by cocks, the latter serving to control the circulation of the juice. The cosettes which leave the top of the diffuser are then expressed; the press-water, or the press-water mixed with molasses, may be introduced by means of a funnel into the diffuser at such a depth below the surface that its sugar-content is equal to that of the juice at that depth. The juice which drains through the conveyor casing passes into a back, and thence, together with the juice

from the bottom of the diffuser, through a reheater, to be mixed, afterwards, with fresh cossettes. The juice which overflows from the back passes to the saturators; if desired, the juice from the bottom of the diffuser may be sent to the saturators direct. Both the juice that goes to the reheater, and that which goes to the saturators, should be freed from pulp; the latter, after admixture with a little juice, is pumped into the lower part of the diffuser.—L. E.

Sugar juices, etc.; Process for the purification of — by means of hydrofluosilicic acid. Soc. Civile des Brevets du A. Schoonjans. Ger. Pat. 213,126, Sept. 26, 1907.

THE content of potassium combined with organic acids present in the sugar juice is first determined in a small portion, for example, by precipitation with tartaric acid, and then the juice is treated with a quantity of hydrofluosilicic acid sufficient only to precipitate this portion of the potassium. It is claimed that in this way the precipitate produced is of a crystalline form and filters readily. The potassium salts of inorganic acids left in the juice are said to have no injurious influence on the crystallisation of the sugar.—A. S.

Dextrine, gum, starch, or like materials; Manufacture of —. C. Hervey, Salford. Eng. Pat. 20,484, Sept. 29, 1908.

THIS invention relates to the manufacture of dextrin, gum, starch, etc., from farinaceous or mealy substances. The raw material is mixed with only a sufficient quantity of salt solution or salt and acid (mineral or organic acid or acids) solution to render it damp; e.g., 1 ton of raw material is mixed with a solution of 20 lb. of sodium chloride in about 20 gallons of water. The mixture is powdered and graded in a dressing machine, and the fine powder is then submitted to the action of an electric current until the desired degree of conversion is attained, the product finally being passed through another dressing machine.—L. E.

Carbohydrates into hydrocarbons; Process for converting —. A. Heinemann, London. Eng. Pat. 13,252, June 22, 1908.

CARBOHYDRATES are converted into levulinic acid, $\text{CH}_3\text{CO}\cdot\text{CH}_2\cdot\text{CH}_2\cdot\text{COOH}$, by treatment with dilute sulphuric or hydrochloric acid. When this is heated to $130^\circ\text{--}140^\circ\text{C}$. with $1\frac{1}{2}$ parts of phosphorus trisulphide, thiitolene,

distils over. Instead of phosphorus trisulphide, sulphur, hydrogen sulphide, or alkali or other sulphides may be used. If phosphorus pentasulphide is used, hydroxythiitolene is produced; this is converted into thiitolene by reduction. The thiitolene is now passed, together with hydrogen or water-gas, through a tube containing finely-divided metal (e.g., copper or nickel), heated to $300\text{--}500^\circ\text{C}$., when the sulphur is eliminated and methylbutine, C_5H_8 , or $\text{CH}_2\text{C}(\text{CH}_3)\cdot\text{CH}:\text{CH}_2$, is produced. When a temperature above 500°C . is employed, the polymer, $\text{C}_{10}\text{H}_{16}$, is formed.—T. F. B.

XVII.—BREWING, WINES, SPIRITS, &c.

Malt; Proteolytic enzyme of —. P. Schudrowitz. J. Inst. Brewing, 1909, 15, 592–595.

THE author has determined, by the method previously described (this J., 1903, 958), the proteolytic capacities of a number of malts, prepared under known conditions from barleys of known origin of the season 1904. A table is given showing the values obtained, together with the other analytical numbers for the malts. In general, the proteolytic capacities show a much smaller range than do the corresponding diastatic powers, probably owing to the fact that the proteolytic enzyme is of a much more sensitive nature than diastase. At the same time there are a number of cases in which the figures for proteolytic capacity appear to give useful hints which are not afforded by the figures for diastatic power.—T. H. P.

Yeast; A new method for purifying infected —. G. Thevenot. Amer. Brew., 1909, 8, 397. Z. Spiritusind., 1909, 32, 461.

THE researches of Hemeberg on the purification of infected yeast by washing in antiseptics have been continued by the author who finds that dilute sulphuric acid yields the best results. Very small quantities of the acid destroy bacteria while notably larger concentrations are necessary to affect yeast cells. In practice the author prefers to use a solution of ammonium persulphate which yields by hydrolysis, ammonium sulphate, sulphuric acid and free oxygen. 75–100 lb. of yeast are diluted with an equal weight of water containing 1 lb. of ammonium persulphate; after standing over night the liquid is drawn off and the yeast washed with water.—R. L. S.

Dextrose, mannose, and fructose; Fermentation of — by yeast-juice. A. Harden and W. J. Young. Roy. Soc. Proc., 1909, 81B., 336–347.

THE results communicated previously by the authors (this J., 1906, 490 and 1111; 1908, 870) were obtained exclusively with dextrose. In the present paper an account is given of the behaviour of mannose and fructose towards yeast-juice both in the presence and absence of added phosphate. Buchner examined the fermentation of fructose by yeast-juice and found that it proceeded at precisely the same rate as that of dextrose, but no experiments with mannose appear to have been performed. The fructose employed in the authors' experiments was Kahlbaum's fructose prepared from inulin. The mannose was prepared by the hydrolysis of ivory-nut and was purified by conversion into the phenylhydrazone, which was recrystallised from hot water and was finally decomposed by benzaldehyde in the usual manner. All the experiments were carried out at a temperature of 25°C . in the presence of toluene. The results of the investigation show that mannose behaves towards yeast-juice, both in the presence and absence of added phosphates, in the same manner as does dextrose. Fructose resembles dextrose and mannose in its behaviour towards yeast-juice, but in the presence of phosphates it is much more rapidly fermented than the other sugars, and the optimum concentration of phosphate is much higher. Fructose has the property of inducing rapid fermentation in the presence of yeast-juice in solutions of dextrose and mannose containing such an excess of phosphate that fermentation otherwise proceeds very slowly. This property, taken in connection with the facts that fructose is rapidly fermented in the presence of phosphate, and that the optimum concentration of phosphate for fructose is much higher than for dextrose or mannose, appears to indicate that fructose when added to yeast-juice does not merely act as a substance to be fermented, but, in addition, bears some specific relation to, or actually forms a permanent part of, the fermenting complex. No similar property is possessed by dextrose or mannose. W. P. S.

Brewing waters; Determination of gypsum and other salts in treated —. H. F. E. Hulton and F. E. Day. Brewers' J., 1909, 45, 620.

By determining the sp. gr. of solutions of gypsum of various concentrations the authors find that the increase

of sp. gr. is exactly proportional to the amount of gypsum in solution, which amount can be ascertained by the use of an appropriate factor. Each grain of dissolved gypsum per gallon corresponds with an increase in sp. gr. of 0.0114 of a degree (water—1000) so that by multiplying the difference in sp. gr. of the treated and untreated waters by 1.0-0.114, or 88.1, the number of grains of gypsum which have been dissolved in each gallon of water is obtained. The method may be applied to the determination of added salts other than gypsum, and the following factors are given for obtaining the number of grains per gallon of various salts: calcium carbonate, 44; crystallised magnesium sulphate, 135; anhydrous magnesium sulphate, 66; anhydrous sodium carbonate, 64; sodium chloride, 100; anhydrous sodium sulphate, 73; potassium sulphate, 85; potassium nitrate, 111.

—W. P. S.

Wine: Phosphoric compounds in —, P. Carles. Bull. Soc. Chim., 1909, 5, 962—969.

THE author has determined in a number of Gironde wines, the total phosphoric acid and the amount present as inorganic phosphate, the difference between these amounts giving the phosphoric acid combined with organic compounds. The majority of the wines examined contained phosphoric acid in both forms. Contrary to the generally accepted view that the organic phosphate is present as lecithin, the author's experiments indicate that more probably it is present as potassium or calcium glycerophosphate. Normally the organic phosphate corresponds to about one-tenth of the total or one-fifth when calculated as glycerophosphate. In the Gironde red wines the amount of phosphoric acid as inorganic phosphate varies from 0.59 to 0.235 gm. per litre, that as organic phosphate from 0.13 to 0.005 gm. The white wines contain 0.6 to 0.10 gm. of phosphoric acid present as inorganic phosphate per litre and up to 0.05 gm. as organic phosphate. The maximum of inorganic acid is found in the red "palus" wines grown on the old alluvial soils of the Garonne and in the White Sauternes; the red "palus" wines also contain most organic phosphate, but the amount is very variable. The phosphoric acid content of the Gironde wines deserves consideration in connection with their physiological value.—E. F. A.

Salicylic acid: Determination of — in wine, W. D. Bigelow. U.S. Dept. of Agric. Bull. No. 122, 1909, 64—67.

AFTER carrying out a number of experiments with different solvents for the extraction of the salicylic acid, the author recommends the following method for the determination of salicylic acid in wine. One hundred c.c. of the sample are acidified with 5 c.c. of sulphuric acid (1:3), 50 c.c. of either carbon tetrachloride or toluene are added, the mixture is gently but thoroughly mixed, and the solvent separated by centrifugal action. Twenty-five c.c. of the solvent are then transferred to a weighed flask, the solvent is allowed to evaporate spontaneously, and the residue is weighed. The residue is then dissolved in alcohol, and titrated with $N/100$ barium hydroxide solution; each c.c. of this solution corresponds with 0.00138 gm. of salicylic acid. This gravimetric and volumetric determination was found to be the more accurate when the amount of salicylic acid present was not less than 0.025 gm. per 100 c.c. With smaller quantities it was found to be better to dissolve the residue of salicylic acid in alcohol, and determine the quantity colorimetrically with ferric chloride, after diluting the alcoholic solution with water.—W. P. S.

Wine vinegar bacteria, A. J. Perold. Zentralbl. Bakt., n. Parasitenk., 1909, II. Abt., 24, 13—55. Chem. Zentr., 1909, 2, 1364.

THE results of the author's investigations of wines of different origin show that each type of wine contains a distinct kind of acetic bacteria. Sweet wines of high gravity contain acetic bacteria which are powerful producers of acid, whilst the lighter Mid-European wines contain acetic bacteria which are less active in this respect. It was not found possible to isolate two different kinds of acetic bacteria from one wine. The proportions of

alcohol required to prevent the souring of the wines are different for the different kinds of bacteria, amounting to as much as 15.5—16 per cent. by volume in the case of the bacteria of sweet wines of high gravity.—A. S.

Spirits: Methods of analysis of distilled —, L. M. Tolman and W. E. Hillyer. U.S. Dept. of Agric., Bull. No. 122, 1909, 206—212.

A FEW modifications of some of the methods adopted by the Association of Official Agricultural Chemists (U.S.A.) are suggested, the alterations mentioned having been found to be of value.

Determination of colouring matters.—Fifty c.c. of the whiskey are evaporated to dryness, the residue is dissolved in 26.3 c.c. of 95 per cent. alcohol and diluted to a volume of 50 c.c. with water. Twenty-five c.c. of this solution are placed in a separating funnel and mixed with 20 c.c. of a solution consisting of 100 c.c. of amyl alcohol, 3 c.c. of syrupy phosphoric acid and 3 c.c. of water. The mixture is agitated and allowed to separate three times successively, the aqueous layer being then drawn off and diluted to a volume of 25 c.c. with 50 per cent. alcohol. The coloration of this solution is then compared in a colorimeter with that of the remaining 25 c.c. which have not been treated with the amyl alcohol mixture, the percentage of colour insoluble in amyl alcohol being thus obtained, that is to say, curand can be separated from the natural colouring matter of the whiskey. The natural colouring matter can also be determined by evaporating 50 c.c. of the sample to dryness, taking up the residue with 15 c.c. of water, filtering the solution, and washing the filter until the filtrate measures nearly 25 c.c. About 26.3 c.c. of 95 per cent. alcohol are then added to the filtrate, and the volume is made up to 50 c.c. by the addition of water. The colour of this solution is then compared with that of the original sample, the reading, subtracted from 100, giving the percentage of natural colouring matters.

Determination of fusel oil.—A few modifications in the Allen-Marquardt method (see Schidrowitz, this J., 1902, 815) are suggested. In the extraction part of the method the carbon tetrachloride used should be of the highest purity, and two washings with sodium sulphate solution are considered to be necessary in order to remove all sodium chloride from the carbon tetrachloride extract. The oxidising part of the process is carried out as follows:—Exactly 50 c.c. of a solution, prepared by adding 200 c.c. of concentrated sulphuric acid to a solution of 200 grms. of potassium bichromate in 1800 c.c. of water, are added to the carbon tetrachloride solution of the higher alcohols and the mixture is boiled gently for 8 hours under a high reflux condenser. The mixture is then transferred to a separating funnel, and the bichromate solution is separated from the carbon tetrachloride. The latter is washed free from bichromate, and the total bichromate solution and washings are collected in a 500 c.c. flask and diluted to the mark with water. Two hundred c.c. of this solution are then treated with 50 c.c. of potassium iodide solution (100 grms. of the salt to 100 c.c. of water), 50 c.c. of approximately $\frac{3}{4}N$ -sodium thiosulphate solution, and 20 c.c. of concentrated hydrochloric acid. The excess of bichromate is then titrated with $N/10$ sodium thiosulphate solution. A blank determination is carried out at the same time, starting at the point where the carbon tetrachloride is washed with sodium chloride. The difference in the number of c.c. of $N/10$ thiosulphate solution used in the actual determination and in the blank corresponds with the amount of fusel oil present. Each c.c. of $N/10$ thiosulphate solution is equivalent to 0.001773 gm. of amyl alcohol, in terms of which the fusel oil may be expressed. This factor was obtained by actual experiments with amyl alcohol.—W. P. S.

Fusel oil: Determination of — by alkaline permanganate, A. S. Mitchell and C. R. Smith. U.S. Dept. of Agric., Bull. No. 122, 1909, 199—205.

THE authors have worked out the conditions necessary to produce definite oxidation of the various higher alcohols by alkaline potassium permanganate solution, and suggest the following process for the determination of the higher alcohols obtained in the carbon tetrachloride

extract from distilled spirits. This carbon tetrachloride solution of the alcohols, obtained as in the Allen-Marquardt process (see Schidrowitz, this J., 1902, 815), is placed in a separating funnel, 10 c.c. of potassium hydroxide solution (1:1) are added, and the mixture is cooled to a temperature of approximately 0° C. Exactly 100 c.c. of a 2 per cent. potassium permanganate solution are placed in a flask and also cooled to 0° C., the bulk of this solution being then added to the contents of the separating funnel. The funnel is now removed from the ice-bath, its contents are shaken for 5 minutes, and allowed to stand for 30 minutes, during which time the mixture attains the ordinary temperature. One hundred c.c. of hydrogen peroxide solution of a strength slightly in excess of the permanganate solution are next placed in a 1-litre Erlenmeyer flask, 100 c.c. of 25 per cent. sulphuric acid are added, and the contents of the separating funnel are then run in gradually with constant shaking. The funnel and the flask containing the residue of the permanganate solution are rinsed with water and the washings are added to the peroxide solution. The excess of hydrogen peroxide is then titrated with an accurately standardised potassium permanganate solution containing about 10 grms. of the salt per litre. A control experiment is run at the same time, using the same amounts of the various solutions. One gm. of potassium permanganate is equal to 0.475 gm. of propyl alcohol, or 0.585 gm. of isobutyl alcohol, or 0.696 gm. of amyl alcohol. Consequently, the difference in the amount of permanganate consumed in the two determinations, expressed in grms. and multiplied by 0.696, gives the quantity of alcohols present in terms of amyl alcohol.—W. P. S.

PATENTS.

Malt; Process of saccharifying —. C. Schwensen and W. Lazarus, Kiel, Germany. Eng. Pat. 19,212, Sept. 12, 1908.

THE mash is saccharified at a temperature of from 30° to 75° C. and the wort is separated and filtered through the husks until it is perfectly clear. The residue of husks is then heated under pressure to a temperature of from 110° to 200° C. until the starch remaining in the residue is opened up. After cooling to 70° C. it is mixed with a part or the whole of the clear wort obtained in the first operation, and the saccharifying process is carried to completion, with or without increasing the temperature. The opened-up starch in the residue of husks may be saccharified by means of a specially prepared malt extract when it is desired to manufacture beer containing a large quantity of dextrin.—W. P. S.

Malt; Apparatus for making —. G. J. Meyer, Buffalo, N.Y. U.S. Pat. 936,011, Oct. 5, 1909.

THE malting apparatus comprises an upright rectangular malting chamber, having perforated side inlet and outlet walls and perforated end walls, and adapted to contain a body of grain; also means for causing a current of air to flow through the chamber and body of grain, the chamber having inoperative portions adjacent to the corners between its air-outlet wall and its end walls. Another form of the apparatus has an inlet at its upper end and an outlet at its lower end and a vertically movable "follower" arranged in the lower part of the chamber operating to open and close the outlet.—J. F. B.

Refrigerators and the like, particularly for use in brewing. M. Dand, Steyning, Sussex, and Lawrence and Co., Ltd., London. Eng. Pat. 20,045, Sept. 23, 1908.

THE refrigerator consists of two vertical corrugated cooling surfaces mounted in a frame so that a narrow channel is

formed between them. The cooling liquid flows upwards through this channel. The wort or other liquid is introduced at the top of the apparatus and is spread over the corrugated surfaces by means of a horizontal perforated pipe and a perforated channel. After flowing down the corrugated surfaces the liquid is collected in a trough; to prevent "fobbing," the liquid does not flow directly into the trough but passes over inclined plates and then through a narrow space between the plates and the sides of the trough. The whole apparatus is enclosed by means of hinged, sliding or other type of doors so as to render the refrigerator germ-proof, this arrangement, together with the "anti-fobbing" plates, being the main object of the invention.—W. P. S.

Beer; Method of de-alcoholising —. F. J. Prihyl, Uniontown, Pa. U.S. Pat. 935,814, Oct. 5, 1909.

BEER containing carbonic acid gas and alcohol is heated and sprayed to remove the carbon dioxide. This gas is collected and stored in a separate vessel. The de-carbonated beer is then heated to a temperature of 150° F. and again sprayed to volatilise the alcohol. The de-alcoholised beer is cooled and re-impregnated with the gas previously withdrawn from it, together with a further quantity of gas derived from a newly brewed beer.—J. F. B.

Wines and fermented liquids; Process for sulphiting — with known quantities of sulphur dioxide. J. Laborde. First Addition, dated March 12, 1909, to Fr. Pat. 360,838, Dec. 11, 1905 (this J., 1906, 491).

THE present addition relates to improvements in the design of the bottle holding the liquefied sulphur dioxide. This is made of stout glass and graduated to show the dose contained. The present bottle is more easily charged, and is closed with a rubber stopper, through which passes a tube which is clamped in position by screws and which carries on its extremity the metallic capsule which seals the bottle. The cage, which holds the bottle and the pick for piercing the capsule, has perforated walls through which the gas escapes and is distributed in the form of small bubbles.—J. F. B.

Distilling and rectifying apparatus; Auxiliary plate-chamber for —. R. Vallat. Fr. Pat. 401,001, March 6, 1909. Under Int. Conv., Aug. 10, 1908.

THE arrangement described is intended to be fitted externally round the upper plates of any distilling or rectifying column, and consists of an annular plate chamber, fitted with scrubbing-caps and heating coil. The connection is made in such a manner that the purified spirit coming from the top of the column is caused to undergo a supplementary rectification in the external chamber before it can pass to the condenser, the feints produced in this chamber being returned to the next lower plates of the main column.—J. F. B.

Alcoholic liquids; Distillation and rectification of —. V. Slavicek, Vienna. Eng. Pat. 21,068, Oct. 6, 1908.

SEE Fr. Pat. 391,919 of 1908; this J., 1909, 377.—T. F. B.

XVIII.—FOODS; SANITATION; WATER PURIFICATION, & DISINFECTANTS.

(1.)—FOODS.

Cows' milk; The presence of an anaerobase and a catalase in —. J. Sarthou. J. Pharm. Chim., 1909, 30, 350—351.

BORDAS and Touplain have recently published (this J., 1909, 538) the results of an investigation on the presence of catalases and peroxydases in milk, and they come to the conclusion that the reactions pointing to the presence of these enzymes are, in reality, due to the catalytic action of calcium caseinate. The author does not agree with this opinion, and, in confirmation of the actual presence of catalytic enzymes in milk, draws attention to the anaerobase, discovered by Raulnitz, Dupouy, Gilley, etc., which only produces a coloration with *p*-phenylenediamine in the presence of hydrogen peroxide, and to the catalase discovered by Sarthou, Rullmann and Reiss; this catalase decomposes hydrogen peroxide without yielding a coloration with *p*-phenylenediamine, guaiacol, etc.—W. P. S.

Butter; Influence of acidity of cream on the flavour of —. L. A. Rogers and C. E. Gray. U.S. Dept. Agriculture, 1909, Bull. No. 119.

THE authors' experiments, which are described in detail, show that butter is liable to develop unpleasant flavours, even when stored at very low temperatures (-10°F), and that the amount of alteration increases with the acidity of the cream used in the preparation of the butter. No micro-organisms to which this more rapid deterioration of butter from highly acid cream could be attributed, were found either in the butter or the cream, and the agency of enzymes was excluded by the fact that heating the ripened cream did not check the occurrence of these changes. In the case of butter prepared from pasteurised cream acidified with various acids, there was a gradual development of unpleasant flavours, and from these results it would appear that the acid normally developed in milk by the lactic acid bacteria, or added in the form of pure acid to the cream, produces, or helps to produce, slow decomposition of unstable compounds in the butter. It is possible to make butter on a commercial scale from sweet pasteurised cream without the aid of a "starter," but to avoid too great a loss of fat, special attention must be given to the temperature and speed of churning. Fresh butter made in this way, shows much less change on storage than that made by the ordinary method, but as a rule the flavour of sweet-cream butter will be too mild for the average taste. Woody and other extraneous flavours are also more noticeable in such butter than in butter of a more pronounced flavour.—C. A. M.

Fat; Determination of — in the products of the pork butcher and in other substances containing water. G. Perrier. Ann. Chim. anal. appl., 1909, 14, 367—369.

TEN grms. of the sample are ground in a mortar with 3 to 4 grms. of coarse sand, and to the mixture 20 to 25 grms. of anhydrous sodium sulphate are added. After thorough mixing, the mass is allowed to stand for 30 minutes, and then transferred to a paper cartridge and extracted with anhydrous ether. The ethereal extract is evaporated, and the residue of fat dried.—C. A. M.

Wheat flour in rye flour; Modification of the Bamihl test for detecting —. A. L. Winton. U.S. Dept. of Agric., Bull. No. 122, 1909, 217—219.

THE test depends on the presence of gluten in wheat flour and the absence of considerable amounts of it in rye and other flours. The original test consisted in rubbing up a small quantity of the flour with water on a microscope slide by means of a cover glass, and noting under the microscope whether or not gluten strings or rolls are formed. The objections to the test are that the traces of gluten present in pure rye flour render it impossible to compare at a glance the amount found in pure rye flour with that from a suspected sample. The author's modi-

fication consists in employing a dilute solution of eosin in place of water and dispensing with the microscope entirely. The gluten absorbs the dyestuff and becomes very conspicuous. Parallel tests with pure wheat and rye flours should be carried out for the sake of comparison, and flours containing much bran tissue or coarse lumps should be sifted through bolting-cloth before applying the test.—W. P. S.

Starch in cocoa products; Determination of —. W. L. Dubois. U.S. Dept. of Agric., Bull. No. 122, 1909, 214—215.

THE following method is recommended as being rapid and accurate for the removal of fat and sugar from cocoa previous to the determination of the starch. Four grms. of the cocoa, or 8 grms. in the case of sweetened cocoa, are shaken in an 8-oz. flask with 100 c.c. of light petroleum until the material is completely disintegrated; the mixture is then subjected to centrifugal action, the clear petroleum spirit is drawn off, and the process repeated. This procedure removes practically all the fat, and the residue is then transferred to a flask and the hydrolysis and determination of the starch proceeded with in the usual way. The sugar is removed from sweetened cocoa by treating the fat-free residue with 100 c.c. of water, submitting the mixture to centrifugal action, and separating the clear aqueous solution. It may be necessary to filter the latter if the speed of the centrifugal machine is low. The process is repeated and the residue is transferred to the filter paper and washed with sufficient water to yield a filtrate of 500 c.c. The residue is then hydrolysed.—W. P. S.

Cinnamic acid; Detection of — in foods. W. D. Bigelow. U.S. Dept. of Agric., Bull. No. 122, 1909, 77—78.

THE method proposed is based on the fact that cinnamic acid is oxidised to benzaldehyde by dilute chromic acid mixture. One hundred grms. of the sample (ketchup, for instance) are mixed with 100 c.c. of water and 5 c.c. of sulphuric acid (1:5), and the mixture is extracted with three successive quantities (50, 25, and 25 c.c.) of chloroform. The chloroform extract is rendered ammoniacal and evaporated to dryness. The residue is dissolved in a small quantity of hot water, the solution filtered and evaporated to dryness, and the residue heated to boiling with 5 c.c. of dilute chromic acid mixture (1 part of dilute sulphuric acid saturated with potassium bichromate and 7 parts of water). The odour of benzaldehyde is most strongly developed when the mixture is cooled until sulphuric acid fumes are no longer apparent. The test will detect the presence of 0.025 gm. of cinnamic acid in 1 kilo. of substance. The reaction is also given by cinnamic aldehyde.—W. P. S.

PATENTS.

Whole-milk; Method of and means for warming — before pasteurising. C. A. Carlson, Stockholm. Eng. Pat. 24,239, Nov. 11, 1908.

THE whole-milk is placed in a reservoir from which it is raised by means of a pump into a closed vessel, which delivers it to the pasteuriser. A portion of the milk, however, flows from the closed vessel and over a spiral tube, in which gas is compressed by means of a force pump. The milk absorbs the heat generated by the compression of the gas and is then conducted back again to the main reservoir. Another portion of the milk is circulated round the force-pump and returned to the reservoir; in this way the temperature of the whole-milk is raised before the latter passes to the pasteuriser.—W. P. S.

Milk; Preserved —. T. B. Wagner, Chicago, U.S. Pat. 934,641, Sept. 21, 1909.

THE preserved milk is prepared by condensing a mixture of milk and crystallised dextrose. It is free from objectionable sweetness, is readily soluble in water, and may be kept indefinitely without undergoing change.—W. P. S.

Flour moths; Process for destroying —. W. Roeder, Hanover, Germany. Eng. Pat. 11,353, May 13, 1909.

TURPENTINE, or a mixture consisting of turpentine, 80, linseed oil, 10, and poppyseed oil, 10 per cent., is allowed to evaporate in the rooms or spaces in flour mills for the purpose of killing flour moths. The turpentine or the mixture may be applied to a suitable material, such as woollen waste, which is then hung up in the rooms or attached to the inner sides of the valves of the pipes, to the underside of the covers of the collecting and mixing receptacles, etc.—W. P. S.

Fermentation apparatus [for bakers' use]; An automatic —. A. J. Durand. Fr. Pat. 401,471, March 25, 1909.

THE apparatus consists of three cylindrical vessels of different diameters. The smallest cylinder which contains the dough stands inside the largest vessel, which is only about one-third of the height of the first; the annular space between them contains water. The third cylinder, which is 1 cm. taller than the first, is inverted over this, and resting on the bottom of the largest, constitutes a water-seal over the fermentation vessel of the nature of a gasometer. The top of the inverted cylinder has a double wall, so that the cylinder containing the dough is surrounded on all sides by an insulating envelope. The inverted cylinder has holes in its sides at a convenient height so that an automatic regulation of the pressure takes place when the accumulation of gas becomes sufficiently great to raise the holes above the water-seal. Fermentation thus takes place in a closed vessel, insulated from variations of temperature, and the automatic regulation of the pressure simultaneously regulates the temperature of the mass.—J. F. B.

Coffee free from caffeine; Process of obtaining —. K. H. Wimmer, Bremen, Germany. U.S. Pat. 936,392, Oct. 12, 1909.

SEE FR. Pat. 384,233 of 1907; this J., 1908, 465.—T. F. B.

(B.)—SANITATION: WATER PURIFICATION.

PATENTS.

Refuse destructors. H. N. Leask, Manchester, and E. Damour, Paris. Eng. Pat. 20,649, Oct. 1, 1908.

THE invention consists in placing beyond the combustion chamber one pair or more of regenerators filled with chequer-brickwork. Through one regenerator of each pair the gases from the combustion chamber are passed on their way to the boiler until this regenerator becomes heated to a high temperature; the gases are then turned off into the other regenerator, and air is drawn through the one previously heated until it is cooled again, when the directions of the air and the hot gases are interchanged. By this means a secondary supply of very hot air is continuously obtained and is led to the top of the furnace grate, thus insuring thorough incineration of the refuse. The primary air-supply is heated in a recuperator placed beyond the boiler and is led to the bottom of the furnace grate.—J. H. J.

[*Water*] *filters*. F. Candy, London. Eng. Pat. 22,524, Oct. 23, 1908.

THE patent relates to improvements in closed filters in which the water is passed downwards under pressure. The water on entering the chamber flows over the outside of a cone, being broken up by annular ribs round the cone, and falls evenly over a toothed rim at the bottom of the cone on to the top layer of filtering medium. Under the upper layers of filtering medium and above the middle layers of sand, a space is left, and by a pipe leading into this space a mixture of water and a coagulant or other

material is introduced and spread over the surface of the sand. Into this space also water can be injected through a pipe with fish-tail nozzles giving a horizontal jet, for the purpose of scouring the surface of the sand during the process of cleaning the filter by a reversal of the flow. This scouring action can also be secured by a shaft with arms revolving in the space mentioned and carrying dependent plates or other means for scraping the surface of the sand. The various layers of the filter material are supported on grids of metal tubes flattened together at their points of support on a frame but otherwise with a small space between each pipe.—J. H. J.

Water filters. E. C. R. Marks, London. From Oliver-Roche Co., New York. Eng. Pat. 27,271, Dec. 15, 1908.

IMPROVEMENTS are claimed in the type of apparatus which comprises an outer case provided with a chamber for purified liquid in the bottom, and a chamber for unpurified liquid in the upper portion, the latter chamber containing a floating filter-tank connected with the lower chamber by a flexible conduit. The improvements consist in the provision of an intermediate cooling chamber between the upper and lower chambers, and of a special filter in the filter-tank. The filter comprises a number of separate metallic screens of different electric potential, and without any electrical connection by a metallic conductor within the filter; a layer of granular charcoal is disposed between the screens. By means of this filter, which for instance may consist of an upper fine copper screen, a lower, coarser screen of zinc or galvanised iron and an intermediate layer of granular charcoal, sufficient oxygen may be liberated from the water to destroy undesirable bacteria.—L. E.

Water; Purification of —. E. E. M. Payne and W. H. Staynes, Leicester. Eng. Pat. 6935, Mar. 23, 1909.

CAUSTIC soda is added to a solution of disodium phosphate producing trisodium phosphate and leaving in excess the calculated amount of caustic soda necessary to combine with the carbonic acid and acid carbonates present in the water to be treated. This solution is added to the water, the mixture agitated and allowed to settle. Carbonates and phosphates of the bases present are formed as a bulky precipitate which carries down with it any suspended matter in the water. The clear water is drawn off, and the sludge run off on to draining beds and air dried. The resulting powder is treated with sulphuric acid and soda-ash, and the sodium phosphate regenerated.—J. H. J.

Water; Method of purifying —. W. B. Bull, Chicago, Ill. U.S. Pat. 935,637, Oct. 5, 1909.

THE water is charged with carbon dioxide, passed through a mass of finely-divided iron, and finally treated with slaked lime or lime water.—J. W. H.

Water-distilling apparatus. W. H. Shephard, Portsmouth, Va. U.S. Pat. 935,932, Oct. 5, 1909.

CYLINDRICAL water chambers project into each end of a horizontal drum, and are connected together by a number of horizontal water-tubes and one horizontal steam-tube. The ends of the steam-tube which project into each water chamber are slotted and provided with strainers. The horizontal drum forms the steam jacket for heating the water contained in the chambers and tubes.—J. W. H.

Sewage and waste waters; Apparatus for the biological purification of —. J. J. E. Donzal. Second Addition, dated March 23, 1909, to Fr. Pat. 385,573, March 21, 1907 (this J., 1908, 639, 764).

THE liquefaction tank of the apparatus (*loc. cit.*) is divided into two compartments by means of a vertical partition having a number of holes near its lower end. The sewage is delivered into the first compartment, and, after passing into the second compartment and through two horizontal perforated partitions placed across the latter, is delivered, by means of an automatically acting siphon vessel, over the surface of the filter beds contained in the oxidising tank. These beds are supported on open pipes, and a

space is left between the sides of the beds and the walls of the tank in order to ensure complete ventilation of the beds.—W. P. S.

Ozonisation ; Process of direct —. A. Breydel. Fr. Pat. 401,401, March 30, 1909.

LIQUIDS or other bodies are submitted to the direct action of the electric discharge by being made to pass, in a capillary thickness, over a series of superposed plates of dielectric material, in the interior of which are metallic armatures, and between which the discharge passes. If the substance be pasty or a solid, it is spread in a very thin layer on an endless band which passes between the dielectric plates. It is claimed for the process, that a preliminary fulguration of the germs takes place in the space above the substance, the molecules of which come into direct contact with the nascent ozone; this is, therefore, instantly utilised and no cooling is required.

—F. SOHN.

Ozone ; Apparatus for treating liquids with —. Felten und Guilleaume-Lahmeyerwerke Actien-Ges. Fr. Pat. 401,599, April 2, 1909.

THE patent is for an apparatus for treating liquids with ozone, in which very intimate contact is brought about by subdividing the liquid into very fine streams or drops. An apparatus is described by way of example, which consists essentially of an ozone generator and a mixing device which may be attached to a water tap, if water be the liquid in question. Ozonised air or oxygen is aspirated into this mixer by the stream of water, and the water is broken up in the mixer by passing through a succession of perforated cups arranged as baffles. The mixture of water and gas then enters an outer chamber, in striking against the wall of which the water is further subdivided, and complete absorption of the ozone may be attained. The whole apparatus is arranged to work automatically; as soon as the tap is turned on, communication with the ozoniser is opened and the electric discharge started by means of a special valve and interruptor; valves also prevent the possibility of water getting back to the ozone generator.—F. SOHN.

Sewage and the like ; Apparatus for the bacteriological treatment of —. G. A. Lucas, Levallois-Perret, France. U.S. Pat. 936,464, Oct. 12, 1909.

SEE Eng. Pat. 21,444 of 1906; this J., 1907, 1062.—T. F. B.

(C).—DISINFECTANTS.

Disinfectants, and methods of testing the same. H. Bechhold. Ver. deutsch. Chem., Sept., 1909. Z. angew. Chem., 1909, 22, 2033—2035.

THE following suggestions are made as to the testing of disinfectants:—(1). In all cases the disinfectant should be removed, after action, by a suitable solvent, instead of being rendered inoperative by chemical means; comparable results, under conditions resembling those obtaining in practice, are thus obtained. (2). Disinfectants are found to have very different relative values when tested on different micro-organisms; tests should therefore be extensive, instead of being confined to one species of organism. (3). Many micro-organisms are damaged on drying as in Krönig and Paul's method; in such cases it is found best to allow the disinfectant to act on freshly grown agar-culture. Attention is also drawn to the value of the halogen-substituted naphthols as disinfectants. Experiments show that some of these compounds are more powerful than any disinfectant in present use, except mercuric chloride; compared with lysol, for instance, which (reckoned on its cresol content) prevents the growth of *Staphylococcus* in dilutions of 1:1000, tribromonaphthol may be noted, which kills this bacterium in dilutions of 1:250,000. These compounds have the further advantage of being odourless and non-poisonous.

—F. SOHN.

PATENT.

Fungicides. P. S. U. Pickering, Ridgmont, Beds., and W. A. Voss, Rayleigh, Essex. Eng. Pat. 17,116, July 22, 1909.

THE object of the invention is to make a paste, consisting mainly of basic copper sulphate, capable of ready diffusion in water and of unimpaired activity. For this purpose 100 galls. of 10 per cent. copper sulphate solution are treated with calcium hydroxide solution in quantity sufficient to precipitate all the copper without leaving any perceptible alkaline reaction in the liquid; about 3000 galls. of lime-water are usually required. The precipitate is collected on calico filters and the liquid is allowed to drain away until the paste has the desired consistence. Finely-powdered *Quillaia* bark may be added in quantity not exceeding one-twentieth of the weight of the paste.—W. P. S.

XIX.—PAPER, PASTEBOARD, &c.

Sulphite wood-pulp digestion process ; Production of methyl alcohol in the —. H. Bergstrom. Papierfabrikant, 1909, 8, 970—971.

METHYL alcohol has been obtained in considerable quantities from the condensed vapours blown off after the digestion of wood by the soda process (this J., 1908, 1037; 1909, 37). The author has examined a similar distillate from the sulphite pulp digesters and has found that it contained about 1 per cent. of methyl alcohol. Only a portion of the total methyl alcohol formed passes off with the vapours, a certain amount remaining behind in the waste liquors. This latter observation has a bearing on the proposed utilisation of these waste liquors for the production of ethyl alcohol by fermentation. In connection with the question of the chemical constitution of wood, the author mentions that when wood is boiled under atmospheric pressure with a dilute solution of an alkali hydroxide, ammonia, methyl alcohol, acetaldehyde, and acetone are formed. The same products are also formed from peat and "white moss," but in different proportions.

—J. F. B.

Sulphite wood-pulp waste liquors ; Researches on — [as a feeding stuff]. A. Stutzer. Ges. deut. Naturforscher und Aerzte, Sept., 1909. Z. angew. Chem., 1909, 22, 1999—2005.

THE waste liquors from the manufacture of sulphite wood pulp contain on an average 120 grms. of organic matter and 10—15 grms. of mineral matter per litre. The calorific value of the dry substance, including the mineral matter, is 4250 calories per kilo; the organic matter has a greater calorific value than starch or cellulose. The author has, therefore, been led to investigate the possibility of utilising the large quantities of waste liquors, which now pollute the rivers, for the purpose of feeding cattle. The most deleterious constituent of the liquors in this respect is the sulphurous acid, both free and in the form of salts, that combined with the organic matter being probably harmless. It is impossible to remove the sulphur dioxide by precipitation in the form of calcium monosulphite; chalk apparently has no effect in this direction, and lime removes only a portion of the sulphurous acid. In the case of lime and the fixed alkalis, an abnormally large proportion is required to neutralise the liquors, owing to their action on the carbohydrates to form acid bodies, presumably saccharins; ammonia has no such action. In order to render the liquors available for feeding purposes the proportion of sulphurous acid must be reduced below 0.1 per cent. The only way in which the author has been able to effect this satisfactorily is by combination with an aldehyde, e.g., formaldehyde. If the liquors be concentrated to one-half or one-third of their bulk, a portion of the sulphurous acid is expelled as gas. Before the sulphurous acid can combine with formaldehyde it must be converted into calcium bisulphite. This is best done by the addition of a small excess of calcium carbonate; the liquid still has an acid reaction, owing to the organic

matter, and calcium monosulphite is not produced. The removal of the sulphurous acid is more complete the larger the quantity of formaldehyde added. A sample of liquor containing 2.3 grms. of sulphur dioxide per litre, when treated with 2.5 c.c. of formalin per litre showed only 0.809 grm.; with 5 c.c. per litre this was reduced to 0.369 grm., and with 20 c.c. to 0.016 grm. It is difficult to control the process analytically because a portion of the sulphur dioxide found on distillation with dilute phosphoric acid must be derived from the hydrolysis of harmless organic compounds. In fact, the hydroxymethanesulphonic acid itself, formed by the addition of formaldehyde, is not stable, though more so than the organic sulphonic acids of the liquors. Before the liquors can be used, the excess of formaldehyde must be fixed in a harmless form. This may be done by neutralising the liquid with ammonia; in practice the author makes use of the nitrogenous matters of molasses. Experiments have been made upon sheep with a fodder prepared as follows: 100 litres of waste wood liquor, evaporated to half the volume, treated with powdered limestone and formalin, filtered, further evaporated, then mixed with 20 kilos. of beet molasses and finally with 6.25 kilos. of finely chopped peat-moss. About 20 litres of wood liquor are allowed per 1000 kilos. of body weight of the animal.

—J. F. B.

PATENTS.

Transfer papers; Manufacture of — E. Lövinsohn, Charlottenburg, Germany. Eng. Pat. 22,420, Oct. 22, 1908.

In preparing transfer papers, colours are employed which melt when heated. The design is printed cold on the transfer paper, and since by this method the whole of the pigment is not transferred by a single impression, it is possible to obtain as many as eight transfers from one pattern, owing to the fact that the tints of the fusible colours deepen by the application of heat. Suitable colours are Victoria Green and Blue, Rhodamine, and Ceresine. Other colours may be used if mixed with a non-drying varnish, such as a viscous solution of rosin or copal in mineral oil. (Reference is directed to Eng. Pat. 4471 of 1874, and 17,338 and 17,793 of 1905; this J., 1906, 17; 1907, 16).—J. F. B.

Air-proof and water-proof [metallised] papers and films; Manufacture of — J. D. and B. D. Galay, Moscow. Eng. Pat. 1715, Jan. 23, 1909.

A MIXTURE is made, composed of 3 parts of powdered metal, e.g., aluminium, 100 parts of collodion, containing about 3 per cent. of nitrocellulose, and 2–3 parts of glycerin or castor or other vegetable oil. This emulsion is contained in a trough and the paper to be proofed is drawn through it and then dried. Films are made by pouring the emulsion on a polished plate and evaporating the solvent.—J. F. B.

Waste paper; Process of recovering — S. Finkelstein, Harrisburg, Pa. U.S. Pat. 936,106, Oct. 5, 1909.

PRINTED paper is reduced to a pulp and boiled for about one hour in water to remove the gummy constituents. The pulp is then bleached, by boiling it with a solution of sodium hyposulphite and sulphuric acid for one hour, and finally washed. The bleaching solution contains 4 oz. of hyposulphite and 1 oz. of oil of vitriol per gallon.

—J. F. B.

Soda pulp mills; Treatment of the "black lyes" of — E. L. Rinman. Fr. Pat. 401,856, April 8, 1909. Under Int. Conv., April 14, 1908.

THE organic constituents of the black lyes from soda pulp mills, whether working the sulphate process or not, may be classified as "humous" substances, the sodium compounds of which are decomposed by carbonic acid, and ulmic acids, the salts of which are not readily decomposed. The lyes are concentrated until they contain about 100 grms. of sodium oxide per litre; they are then saturated with carbon dioxide, and a salt, preferably sodium chloride, is added to the extent of 50 grms. per litre. In order to

obtain the humous matters in a granular form, suitable for filtration, the precipitation should be effected at a temperature of 75° C. After precipitation it is desirable to cool the liquid before filtering and to filter as soon as possible. The sodium ulmates remain in solution and exert an action as precipitating salts; the presence of the sodium chloride is stated to be beneficial in the digestion process and to yield a tougher fibre, but it is necessary to increase the quantity of alkali used correspondingly. The purified liquor may be re-causticised and used for a considerable number of times before it is necessary to regenerate the alkali by calcination or crystallisation. Ammonium carbonate may be used to assist precipitation in place of sodium chloride if means are provided for the recovery of the ammonia.—J. F. B.

Celluloid-like products; Manufacture of — A. G. Bloxam, London. From Chem. Fab. Griesheim-Elektron, Frankfurt a/Main, Germany. Eng. Pat. 15,855, July 7, 1909.

THE camphor used in the manufacture of celluloid may be wholly or partly replaced by dihydroxydiphenylsulphone. The product is nearly odourless and is not affected by light.—J. F. B.

Paper and the like; Process and apparatus for marbleizing — H. Metzger, Assignor to Akt.-Ges. f. Buntpapier und Leimfabrik., Aschaffenburg, Germany. U.S. Pat. 936,010, Oct. 5, 1909.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENTIAL OILS, & EXTRACTS.

Alkaloid reactions with perhydrol [concentrated hydrogen peroxide]. E. Schär. Schweiz. Chem. Ges., Sept., 1909. Chem.-Zeit., 1909, 33, 1042.

A MIXTURE of concentrated hydrogen peroxide solution and strong sulphuric acid is a good reagent for several alkaloids. Quinine gives a strong yellow coloration, nicotine a dark chocolate-red. The activity of the reagent is increased in certain cases by the addition of small quantities of colloidal platinum. Under these circumstances strychnine yields a bright purple-red coloration which develops slowly, but is quite stable. A combination of hydrogen peroxide, hydrochloric acid and colloidal platinum can be used in the thalioquin-reaction, and for the detection of caffeine and theobromine, in place of chlorine water and ammonia.—F. SHDN.

Brucinesulphonic acids and the cause of the brucine-nitric acid reaction. (Strychnine alkaloids, 6th Communication.) H. Leuchs and W. Geiger. Ber., 1909, 42, 3067–3075.

BRUCINE was treated with sulphur dioxide and manganese dioxide in a manner similar to that used for the preparation of strychninesulphonic acid (this J., 1909, 905). Three isomeric sulphonic acids were formed, and could be separated owing to their different solubilities in water. Brucinesulphonic acid I., $C_{23}H_{26}O_7N_2S$, can be crystallised from 12 parts of hot water. It is hardly soluble in alcohol, but readily soluble in sodium hydroxide or sodium carbonate solutions, and in 20 per cent. hydrochloric acid. It can be heated to 300° C. without melting, and has $[\alpha]_D = -241.3'$ at 20° C. Acid II. resembles the preceding in its properties. It can be crystallised from 55 parts of hot water, melts with decomposition at 260° C. and has $[\alpha]_D = +29.2'$ at 20° C. in alkaline solution. The third acid has about the same solubility as the second acid, but crystallises in pointed prisms, instead of

rectangular tablets. It decomposes at 245° C., and has $[\alpha]_D^{20} = +156.8^\circ$ at 20° C. in alkaline solution. When brucinesulphonic acid 1. is treated with cold 5N-nitric acid, transparent red crystals are formed, and the liquid when filtered deposits deep-yellow needles. The red substance is a quinone, $C_{21}H_{20}O_7 \cdot N_2S_3H_2O$. It is hardly soluble in organic solvents, but easily soluble in alkalis. Bi-desmethylnitrobrucinesulphonic acid hydrate, $C_{21}H_{23}O_{10}N_2S_3$, is the yellow substance formed by the action of nitric acid on brucinesulphonic acid. It crystallises from 270 parts of hot water in yellow needles, and dissolves in alkalis with a yellow colour. The quinone can be converted into a quinol (hydroquinone) by means of sulphur dioxide, and the substance so formed crystallises from 400 parts of water in colourless needles.

—F. SUDX.

Pilocarpus pennatifolius and *Erythroxylon Coca*; Alkaloids of —. O. Tammann. Ges. dent. Naturforscher und Aerzte, Sept., 1909. Z. angew. Chem., 1909, 22, 1987.

It is general it may be said that in both the plants mentioned in the title, the alkaloids occur mainly in the cells containing little or no chlorophyll; the oxalate cells are always free from alkaloids. The author has determined that in the *Pilocarpus* the largest quantity of alkaloid exists in the epidermis of the leaves, particularly on the upper surface; the chlorophyll granules contain no alkaloid. Tropical plants grown in Europe under glass, if properly tended, may produce as much alkaloid as in their natural state, sometimes even more. Considerable differences were found between different individuals grown in the same house. In *Pilocarpus* the flower stalks and buds contain the highest percentage of alkaloid (0.51 and 0.44 per cent.), and the stems contain the lowest (0.18 per cent.); the leaves and petioles contain 0.23–0.24 per cent. The absolute quantity of alkaloid in the leaves increases as the leaf develops, but the percentage decreases. If stored in a damp room the alkaloid-content of *Pilocarpus* leaves rapidly diminishes; a loss of 50 per cent. was found in the course of six weeks. In the case of *Coca* leaves the quantity of alkaloid does not increase with the age of the leaf. The alkaloids of *Coca* seeds are almost entirely extracted by the steeping water in the process of germination, but the embryonic plant, 4 days old, contains newly-formed alkaloid immediately under the root-point. Both in *Pilocarpus* and *Coca* the alkaloids are waste products which play the part of secretions. The alkaloid-bearing tissues of the pith and the inner nerve-parenchyma are sharply differentiated from their alkaloid-free surroundings and are completely analogous to other secretion tissues, such as tannin ducts and oxalate cells.—J. F. B.

Cheiriline. W. Schneider. Ber., 1909, 42, 3416–3420.

THE author has made fresh ultimate analyses of cheiriline obtained from wallflower seeds (*Cheiranthus cheiri*) and from *Erysimum nanum compactum aureum*. He now adopts the formula, $C_{15}H_{15}O_2NS_2$, which differs from those previously proposed by himself and Wagner (this J., 1909, 106). The behaviour of the base towards sodium hydroxide resembles that of a mustard oil.—F. SUDX.

Umbelliferae; The chemistry of certain drugs of the family of the —. J. Herzog and D. Krohn. Ges. dent. Naturforscher und Aerzte, Sept., 1909. Z. angew. Chem., 1909, 22, 1988–1989.

It has previously been shown that the pimpinellin obtained from *Pimpinella* possesses the chemical properties of a lactone; the authors have now isolated similar bodies from other plants of the family of the *Umbelliferae*. The *Rhizoma Imperatoriae* yielded by a special process of extraction four different chemical compounds: *Oxy-pucedanin*, $C_{13}H_{12}O_4$, m. pt. 142°–142.5° C., yield 1.3 per cent.; *ostruthin*, $C_{15}H_{16}O_3$, m. pt. 118°–119° C., yield 0.5 per cent.; *ostruthol*, $C_{24}H_{24}O_8$, m. pt. 134°–134.5° C., yield 0.3 per cent.; *osthol*, $C_{15}H_{16}O_3$, m. pt. 83°–84° C., yield 0.1 per cent. From the *Rhizoma Pucedani* there were likewise obtained: *Pucedanin*, m. pt. 109° C., yield 2 per cent., and *oxy-pucedanin*, yield

0.3 per cent. All these bodies show the properties of lactones, being soluble in excess of alkalis and re-formed from their neutral salts by the action of the carbon dioxide of the air. The authors have studied oxy-pucedanin in some detail. It forms addition products with the hydracids and is converted into an isomeride on boiling with 10 per cent. sulphuric acid; this isomeride does not combine with the hydracids. Oxy-pucedanin contains no free hydroxyl group; when boiled with 1 per cent. sulphuric acid it combines with 1 molecule of water, and this hydration product contains a hydroxy-group. On reduction with aluminium amalgam, oxy-pucedanin combines with only one atom of hydrogen per molecule and the product, according to molecular weight determinations, has the formula $(C_{13}H_{15}O_4)_2$. Ostruthin also forms an addition product with hydrogen chloride; so does osthol, which latter contains a methoxyl group in its molecule.—J. F. B.

Caragana arborescens and its bitter principle [caraganin]. E. Reeb. J. Pharm. Elsass-Lothring., 1909, 86. Pharm. Zentralh., 1909, 50, 738.

Caragana arborescens, a native of the Urals, is widely cultivated as a horticultural plant. Its leaves contain a bitter glucoside, *caraganin*. The dried extract obtained with 95 per cent. alcohol was redissolved in a very little water, and the glucoside salted out from the aqueous solution by means of sodium sulphate. The precipitate was washed with a saturated solution of the same salt, and then extracted with alcohol. The solvent was distilled off and the residue again treated as before with water and sodium sulphate. The process was repeated three or four times; the partly purified glucoside was then precipitated with lead acetate. After liberation from the lead compound by means of hydrogen sulphide, in the usual manner, caraganin was obtained in yellow scales, or as a yellow powder, on evaporation. It has an intensely bitter taste; gives a chestnut-brown colour with sulphuric acid; gives indigo-blue streaks with sulphuric acid and ammonium molybdate; and a dirty green colour with nitric acid. If a layer of Lafou's reagent (sulphuric and selenious acids) be floated over a solution of caraganin, a peach-coloured ring will be formed. Caraganin is hydrolysed with formation of dextrose, by heating with dilute mineral acids.—I. O. B.

Medicinal plants in relation to their therapeutic activity; Sterilisation of —. E. Perrot and A. Goris. Bull. d. Sci. pharm., 1909, 16, [7].

THE authors have prepared from different vegetable substances so-called "physiological extracts" which contain the complex constituents of the plants in their original condition. Their experiments shew that the bark of the horse-chestnut tree contains a compound of aesculin and aesculannic acid, which is easily decomposed by long boiling when in solution. An extract which contains such a compound in the undecomposed state, may differ in its action from a solution where decomposition has taken place. In order to get a suitable extract of kola, the nuts must be sterilised and extracted with alcohol (this J., 1908, 996). Digitalis leaves when sterilised, preserve their colour and odour. If the leaves are then extracted with 80 per cent. alcohol, the extract evaporated at the ordinary temperature, and the residue treated with ether, a yellow coloured powder is obtained, soluble in water, which the authors term the "physiological extract" of digitalis.—F. SUDX.

Citral; Determination of — in terpenoid essence of lemon. S. H. Baer. U.S. Dept. of Agric., Bull. No. 122, 1909, 229–230.

THE colorimetric method for the determination of citral is only applicable if pure citral, distilled water, and aldehyde-free alcohol be employed in the manufacture of the essences. Such is never the case, and on this account, together with the fact that no indication is obtained as to whether the citral used is prepared from lemon oil or lemon-grass oil, the author is of opinion

that the colorimetric method requires further examination before it can be adopted as an official process.

—W. P. S.

Samphire oil; Composition and fractionation of —.
F. Borde. Bull. Sci. Pharmacol., 1909, 16, 393—399.
Chem. Zentr., 1909, 2, 1335.

By fractional distillation *in vacuo*, the author has isolated four constituents from samphire oil (see this J., 1909, 623), viz., (1), a terpene, b.pt., 158°—160° C.; sp. gr. at 0°/4° C., 0.8703; $[\alpha]_D^{20} = +44.37'$; iodine value (mols.), 336; this is probably *d*-pinene; (2), an optically inactive hydrocarbon of the composition, $C_{15}H_{26}$; b.pt., 176°—180° C.; sp. gr. at 0°/4° C., 0.8957; iodine value, 175.5; (3), a compound of b.pt. about 210° C.; sp. gr., 0.95023; iodine value, 156; $[\alpha]_D^{20} = +1.4'$; and (4), an isomeride of apiol; b.pt., 285°—295° C.; sp. gr. 1.1753; iodine value, 119 (see this J., 1909, 906). The quantities of these four constituents present in the oils from the fruits, from the leaves and stalks, and from the whole plant, respectively, are shown in the following table:—

	Oil from:		
	Fruits.	Leaves and stalks.	Whole plant.
	per cent.	per cent.	per cent.
Active hydrocarbon .	12	18	15
Inactive hydrocarbon .	48	17	49
Compound of b. pt. 210° C.	5	5	5
Apiol isomeride	35	60	49

—A. S.

Cloves; Determination of the essential oil and the eugenol in —. R. Reich. Z. Unters. Nahr.- u. Genussm., 1909, 18, 401—412.

THE direct determination of the essential oil in cloves can be satisfactorily carried out in a special form of steam-distillation apparatus. By this method the powdered cloves are packed into a small steam-jacketed cartridge, through which steam can be led into a condenser. The distillate is shaken with a suitable solvent, the extract is evaporated, and the residue weighed. To determine the eugenol, 1.0—1.5 gm. of the oil is warmed on the water-bath with 20 c.c. of 5 per cent. sodium hydroxide. 20 c.c. of light petroleum are added, and the aqueous portion made up to 30 c.c. with sodium hydroxide solution. 5 c.c. of 25 per cent. sulphuric acid are added to one-half of the alkaline liquid, followed by the addition of 6 grms. of common salt. 20 c.c. of pentane are now added, the liquid shaken, and after standing, an aliquot portion is removed and evaporated in a tared flask. Amboua cloves contain 21.3—22.1 per cent. of oil, and 17—17.6 per cent. of eugenol. Zanzibar cloves contain 18.4—20.1 per cent. of oil, and 15.4 to 16.6 per cent. of eugenol. The clove stalks contain 5.8 to 6.7 per cent. of oil, and 5.4—5.7 per cent. of eugenol. The anthophylli contain 2.2 to 9.2 per cent. of oil. The oil from Amboua cloves contains 79.0—80.6 per cent. of eugenol, that from Zanzibar cloves 80.0—86.1 per cent., that from commercial clove powder 85.0—87.9 per cent., from clove stalks 83.1—84.5 per cent., and from the anthophylli 85.5 to 85.9 per cent. Commercial ground cloves contain 17.0—19.3 per cent. of oil and 15.5 to 16.3 per cent. of eugenol.—F. SHDN.

Sesquiterpenes. 3rd communication. "Caryophyllene" from oil of cloves. Gurjun balsam oil. A method of preparation of the nitrosochlorides of mono- and sesquiterpenes. E. Deussen. Annalen, 1909, 369, 41—59.

It has been shown that caryophyllene nitrosate (m.pt. 148°—149° C.) yields a nitrolamine base melting at 128° C. The same substance can be obtained from inactive α -caryophyllene nitrosochloride, and should therefore be styled α -caryophyllenenitrolbenzylamine.

When the blue caryophyllene nitrosite is boiled with light petroleum or oxidised with chromic acid, a nitrosate, m.pt. 131°—132° C. and with an optical rotation of about 60°, is produced. This substance may be styled *d*-caryophyllene nitrosate. When the blue nitrosite, m.pt. 115° C. is treated with benzylamine, β -caryophyllenenitrolbenzylamine, m.pt. 172°—173° C. is produced. The sesquiterpene from which the blue nitrosite is derived, the author terms β -caryophyllene, whilst a second sesquiterpene must be present in oil of cloves, and is called γ -caryophyllene. When the blue nitrosite is treated with alcoholic potassium hydroxide, β -caryophyllenenitrosite is produced, which melts at 139° C. A longer action of the same reagent produces a substance, $C_{15}H_{25}NO_2$ or $C_{15}H_{23}NO_2$, melting at 162—163° C. When the blue nitrosite is dissolved in alcohol and subjected to the action of light, a substance, $C_{15}H_{22}N_2O_4$, is produced, which melts at 131°—132° C., and has $[\alpha]_D^{20} = +57.22'$ in benzene solution. It decolorises bromine, and appears to be identical with *d*-caryophyllene nitrosate. If benzene be used in place of alcohol in the above reaction, a saturated compound, $C_{15}H_{24}N_4O_5$, is produced, which melts at 158°—159° C., and is optically inactive. Light has only an accelerating effect on the formation of α -caryophyllene nitrosochloride. The mother liquors left after the preparation of this α -nitrosochloride contain an unsaturated "nitro-compound," $C_{15}H_{23}NO_2$ or $C_{15}H_{25}NO_2$, which melts at 164° C., and has $[\alpha]_D^{20} = +22.4'$ in chloroform. When α -caryophyllene nitrosochloride is treated with sodium methoxide, a substance $C_{15}H_{23}ON$, m.pt. 116° C. is produced. If sodium ethoxide or propylate is used, an unsaturated substance, $C_{15}H_{23}NO$, is obtained, which melts at 128°—129° C. In the mother-liquors left in the preparation of the blue nitrosite, a bicyclic hydrocarbon has been found. This yields a nitrosochloride, m.pt. 116° C., which can be resolved into two isomerides melting at 122° and 146° C. These nitrosochlorides, and β -nitrosochloride, each yield β -caryophyllenenitrolbenzylamine, m.pt. 172°—173° C. When treated with sodium ethoxide, they each yield a substance, $C_{15}H_{25}NO_3$, which is unsaturated, dextro-rotatory, and melts at 162°—163° C. When caryophyllene is treated with sulphuric and acetic acids, a sesquiterpene is found amongst the products. It has the sp. gr. 0.9227 at 19° C., $n_D^{20} = 1.49533$ at 20° C., and it boils at 126°—127° C. at 24 mm. When *isocaryophyllene*, obtained from the mother liquors of the blue nitrosite, is oxidised with permanganate, a small amount of a glycol, $C_{15}H_{24}O_4$, m.pt. 120° C. is produced, with larger amounts of α,α -dimethylsuccinic acid. The same glycol was formed by the oxidation of "caryophyllene," and the oxime was found to melt at 187°—188° C. The "caryophyllene" of clove oil contains three isomeric sesquiterpenes, the α -, β -, and γ -modifications, of which, β -caryophyllene yields the blue nitrosite. A formula for this sesquiterpene is given. Gurjun balsam oil when oxidised in acetone solution with powdered permanganate yields a ketone, $C_{15}H_{24}O$, boiling between 170°—180° C. at 12 mm., and giving a semicarbazone, m.pt. 234° C. An apparatus for the preparation of large quantities of nitrosochlorides is described.—F. SHDN.

Terpenes and essential oils. 101st Communication. O.
Wallach. Annalen, 1909, 369, 63—103.

THE author has carried out a number of experiments with fenchone, the results of which confirm Scumler's formula for this substance (this J., 1908, 181). The work may be summarised as follows: The behaviour of fenchone towards sodium, and towards potassium hydroxide was examined. In the latter reaction, fencholic acid is produced, and is fully described. When the salts of fencholic acid are distilled, a hydrocarbon, $C_{10}H_{16}$, is produced. Fencholic acid amide was treated with bromine and an alkali, and a pure *isocyanate* obtained, as well as fenchylamine. The oxidation products of fencholic acid were also examined. If potassium hydroxide be allowed to act upon *isofenchone*, *isofencholic acid* is produced. The paper concludes with an examination of the action of potassium hydroxide on cyclohexanone.—F. SHDN.

Lemon industry of Italy. U.S. Dept. of Agriculture Bull., 1909. [T.R.]

Calcium citrate.—In 1899 Italy exported 3 million pounds and 17 million pounds in 1908. Of the average shipments the United States took from 32.5 to 40.7 per cent.; France and the United Kingdom were the next heaviest buyers. The imports into the United States rose from 443,981 lb. valued at \$52,137 in 1894, to 3,872,924 lb. valued at \$726,626, in 1907, but fell to 3,853,105 lb. valued at \$580,293 in 1908.

Lemon oil.—The total exports from Italy of lemon oil during the last ten years approximated 1,000,000 pounds per annum, of which quantity the United States took from 21.9 to 38.8 per cent. The shipments were given as follows:—

Year ended December 31.	Quantity.
	pounds.
1900.....	743,024
1902.....	1,197,213
1904.....	886,990
1906.....	971,334
1908.....	1,551,256

From 100,000 lemons of average quality are produced 100 lb. of oil and 675 lb. of calcium citrate, equal to 430 lb. of citric acid. The average prices of these ranges from £16 to £20 for oil and £15 to £19 for citrate. The average value of lemons to the Sicilian grower is about £30 per 100,000, but those used for by-products are worth about £20.

Theobromine-sodium salicylate; Characterisation of commercial.—O. Frey. Z. Allgem. österr. Apoth.-Ver., 1909, 47, 433—434.

THE author has found that determination of the theobromine alone in commercial theobromine-sodium salicylate is not sufficient to exclude unsatisfactory samples. He has drawn up the following scheme. The theoretical composition is represented by the formula.

The substance is a white, microcrystalline, odourless, and hygroscopic powder, with a sweetish but salt-like and alkaline taste, and easily soluble in water. A 20 per cent. solution prepared in the cold is clear and colourless, or at the most, slightly yellow. It has an alkaline reaction, and when acidified with acetic acid gives a violet colour with ferric chloride. Mineral acids precipitate the salicylic acid as well as the theobromine. If 10 grms. of the solution are extracted twice with 10 grms. of chloroform, the chloroform should not leave more than 0.01 gm. of residue. The water present should be determined by heating in a steam-oven. 1 gm. of the dried substance dissolved in 100 grms. of recently boiled and cooled water, should not require more than 2.9 c.c. of N/1 acid using phenolphthalein as indicator. The same weight dissolved in 400 c.c. of water should not require more than 2.9 c.c. of N/1 acid when methyl orange is used. To determine the salicylic acid, 1 gm. of the dried salt is dissolved in water, 3 c.c. of dilute sulphuric acid are added, the free salicylic acid is extracted with ether, the ether evaporated, and the residue dissolved in alcohol and water. The solution should require 26.5 to 27.5 c.c. of N/10 sodium hydroxide using phenolphthalein as indicator. 2 grms. of the dried salt are dissolved in 10 c.c. of water and 5.4 c.c. of N/1-sulphuric acid added. The now neutral liquid is made alkaline with a drop of ammonia, and allowed to stand for 3 hours at 15°–20° C. The precipitated theobromine is filtered off on a tared filter, washed twice with 10 c.c. of water, and dried at 100° C. The weight should be from 0.75 to 0.80 gm.—F. SHDN.

Chinosol [neutral orthohydroxyquinoline sulphate]; Characters and tests for—F. Zernik. Pharm. Zentralh., 1909, 50, 771.

CHINOSOL forms a crystalline, pale yellow powder with a saffron-like odour, and a burning taste. It melts at 175°–177.5° C., is readily soluble in water, sparingly so in

alcohol; insoluble in ether. The 1:49 aqueous solution is acid in reaction; when treated with ferric chloride it gives an intense green colour, and a white precipitate with barium chloride. With sodium carbonate solution it gives a white crystalline precipitate of felted needles, which when collected, washed, and dried in a desiccator should melt at 73° to 75° C. Chinosol should leave no weighable residue when burnt.—J. O. B.

Solubilities of the salicylates of the U.S.P. in aqueous alcohol solutions at 25° C. A. Seidell. J. Amer. Chem. Soc., 1909, 31, 1164—1168.

THE author has determined the solubility of several salicylates, in water, and alcohol, and in mixtures of the two at 25° C. Tables and curves showing the results are given. The following table compares the author's results with those of the U.S.P.:—

	Parts of solvent to dissolve 1 part of salicylate at 25° C.			
	In water.		In 92.3 wt. per cent. alcohol.	
	Author.	U.S.P.	Author.	U.S.P.
Ammonium salicylate.....	0.97	0.9	2.33	2.3
Lithium salicylate.....	0.786	very soluble	1.193	very soluble
Phenyl ".....	6665.0	2333.0	4.65	5.0
Quinine ".....	1538.0	77.0	20.65	11.0
Salicylic acid....	453.0	308.0	2.13	2.0
Sodium salicylate.....	0.867	0.8	7.33	5.5

—F. SHDN.

Salicylates; Methods for the determination of—A. Seidell. J. Amer. Chem. Soc., 1909, 31, 1168—1177.

THE bromate method of Freyer and the iodine method of Messinger and Vortmann for the determination of salicylates have been found by the author to be unreliable. A more satisfactory method is as follows:—The weighed sample of the salicylate, dissolved in a small quantity of water, is placed in a stoppered bottle with 50 c.c. of strong hydrochloric acid. The solution is titrated with N/5 bromate solution, the bottle being shaken and warmed gently after each addition. The bromate is added till the yellow colour of the excess of bromine remains for five minutes after the addition of the last two drops, the temperature being between 80° and 100° C. In this reaction 4 atoms of bromine combine with one molecule of the salicylate. The method gives fairly concordant results. Excess of a standard solution of bromine in hydrochloric acid may be added to the salicylate, and the uncombined bromine determined by means of stannous chloride.—F. SHDN.

Ketones by means of acetoacetic ester; Preparation of pure—A. Michael and K. Wolgast. Ber., 1909, 42, 3176—3177.

IT has been known that dialkylacetoacetic esters are not hydrolysed by cold potassium hydroxide, whilst the mono-alkyl derivatives are readily hydrolysed. When alkyl halides are allowed to act upon the sodium compound of acetoacetic ester, a mixture of mono- and dialkyl derivatives is produced, which may be separated by means of cold potassium hydroxide solution. Ethylacetoacetic ester was prepared in the usual way, and shaken with ammonia. It was then shaken with 5 per cent. potassium hydroxide, when the monoethylacetoacetic ester was hydrolysed and went into solution. The alkaline liquid was acidified after standing, and heated, when methyl-propylketone was produced.—F. SHDN.

Aldehydes and ketones; A general reaction for —. H. Franzen. Ber., 1909, 42, 3293—3295.

SOLUTIONS of potassium cyanide and calcium chloride were mixed and shaken for several hours with benzaldehyde. A bright orange-yellow powder was obtained, which proved to be the calcium compound of mandelic acid nitrile, $[C_6H_5.CH(CN).O]_2Ca$. This substance is partly decomposed by boiling water into benzaldehyde and calcium cyanide, and is only slightly acted upon by boiling alcohol. Dilute acids cause the liberation of mandelic acid nitrile. Solid crystalline substances have been obtained in the same way from several ketones and aldehydes. Barium, strontium, and magnesium cyanides also give the same reaction.—F. SIDN.

Iodine in organic substances; Detection and determination of —. Determination of iodoform in iodoform gauze. V. Paolini. Monit. Scient., 1909, 71, 648.

THE method is based upon the fact that when organic substances, containing small quantities of iodine compounds, are submitted to the action of nascent hydrogen, the iodine is completely converted into hydrogen iodide. For the determination of iodoform in iodoform gauze, the process is as follows:—10 grms. of the gauze, cut into small pieces, are introduced into a half-litre flask and covered with 40 grms. of zinc dust; the mixture is then moistened with 60 c.c. of 25 per cent. sulphuric acid and heated for 2—3 hours, using a reflux tube; 40—50 c.c. of acid are then added and the heating continued for some hours, the end of the reaction being indicated by the gauze becoming colourless. The gauze is now washed by decantation 4 or 5 times and the volume of the solution made up to 1 litre. To 100 c.c. of this liquid, 100 c.c. of carbon bisulphide or chloroform are added and several c.c. of potassium nitrite solution; these are shaken together, the carbon bisulphide washed 3 times, and the iodine titrated with $N/10$ thiosulphate in the presence of sodium bicarbonate.—F. SODN.

Reducing reactions with phosphorous and hypophosphorous acids [and determination of these acids]. Sieverts. See XXIII. Inorg. Quant.

PATENTS.

Arsenoarylglycollic acids and arsenoarylthioglycollic acids; Manufacture of —. O. Imray, London. From Farbwerke vorm. Meister, Lucius, und Brüning. Hoechst a/Main, Germany. Eng. Pat. 4246, Feb. 20, 1909. Addition to Eng. Pat. 9855, May 6, 1908. (See Ger. Pats. 206,057 and 206,456; this J., 1909, 328.)

ARSENOARYLGOLLYLIC acids are produced by the action of powerful reducing agents, such as sodium amalgam or hydrosulphite, on the oxyarylglycolarsinic acids, and arsenoarylthioglycollic acids by the similar reduction of the corresponding thio-derivatives.—J. F. B.

Aminophenylarsinic acid (atoxyl) and its derivatives; Preparation of derivatives of —. A. Monneyrat. Fr. Pat. 401,586, July 30, 1908.

AMINOPHENYLARSINIC acid and its derivatives are converted into their sulphophenyl derivatives by treatment with phenylsulphonic chloride. The products are slightly soluble in water, and form readily soluble salts with alkaline bases and with alkaloïds; the salts of cinchona alkaloïds are mentioned particularly. New derivatives of the composition, $C_6H_5.NH.CO.NH.C_6H_3R.AsO(OH)_2$, are obtained by the action of phenyl isocyanate on amino-arylarsinic acids.—T. F. B.

Esters of phenols chlorinated in a side-chain; Process of making compound — and also hydroxybenzyl alcohols, hydroxybenzaldehydes, and hydroxybenzoic acids. F. Raschig. Fr. Pat. 401,845, April 8, 1909.

WHEN cresols, xylenols, etc., are treated with chlorine, the halogen only enters the benzene nucleus. If, however,

the phenols are converted into their esters by means of inorganic or organic acids, such as carbonic acid, phosphoric acid, and benzenesulphonic acid, and these are treated with chlorine, one, two, or three atoms of halogen can be introduced into the side chain of the phenol. The preparation of the dichlorides of *o*- and *p*-cresol carbonate, the trichloride of *m*-cresol carbonate, the dichloride of *o*-cresol phosphate, the dichloride of *o*-hydroxybenzylidenechloride phosphite ($CHCl_2.C_6H_4.O)_3PCl_2$, and the benzenesulphonate of *o*-hydroxybenzylidene chloride, is described. When these substances, or similar compounds, are treated with saponifying agents (*e.g.*, alcoholic alkali solutions) they are converted into hydroxybenzyl alcohols, hydroxybenzaldehydes, and hydroxybenzoic acids.

—T. F. B.

Salts of organic acids; Process for the preparation of compounds of — with sulphur dioxide. Farb. vorm. Meister, Lucius, und Brüning. Ger. Pat. 212,902, Jan. 9, 1907.

THE process claimed consists in acting on salts of organic carboxylic or sulphonic acids with sulphur dioxide, care being taken that the amount of water present is insufficient to cause formation of the free acids. The process can be carried out by passing sulphur dioxide gas over the powdered salt; by mixing the salt with liquefied sulphur dioxide; or by allowing sulphur dioxide to act on the salt dissolved or suspended in a liquid which possesses no, or only feeble, ionising power. The products are said to be suitable for the preparation of chlorides and anhydrides.—A. S.

Cascara-sagrada; Process for the preparation of a clear extract, soluble in water, not containing zinc, and free from bitterness, from —. M. Penschuck. Ger. Pat. 213,292, Feb. 7, 1909. Addition to Ger. Pat. 206,467.

A SIMPLIFIED form of the process described in the main patent (see this J., 1909, 161) is claimed. The powdered bark is mixed with zinc oxide and with sufficient water to moisten the mass, which is compressed and left for 1—2 hours. It is then warmed on the water-bath to 30°—40° C. and after several hours, extracted with water, and the extract evaporated as described in the main patent.—A. S.

Xanthine and guanine derivatives substituted in the 8-position; Process for preparing —. Farbenfabr. vorm. F. Bayer und Co. Ger. Pat. 213,711, Jan. 18, 1908.

WHEN 4,5-diaminopyrimidines of the general formula,

(where X represents hydrogen or a substituent and Y oxygen or -NH), are treated with fatty acids or substituted fatty acids, 5-acidylamino-4-aminopyrimidines are formed. If these are treated with solutions of alkaline condensing agents, or if their alkali salts are heated, water is eliminated and purine or guanine derivatives substituted in the 8-position are produced. The following fatty acids and derivatives are mentioned:—Acetic, propionic, oxalic, succinic, cyanoacetic, lactic, hippuric, and hydroxyisobutyric acids, acetylglucosyl, ethoxy- and methoxyacetic acids, and α - β -dihydroxypropionic acid.—T. F. B.

Aromatic hydroxylated nitro-compounds; Process for preparing —. R. Wolfenstein and O. Boeters. Ger. Pat. 214,045, Aug. 21, 1907. Addition to Ger. Pat. 194,883, Aug. 4, 1906. (See Eng. Pat. 17,521 of 1907; this J., 1907, 1194.)

By treating aromatic hydrocarbons or their substitution products or derivatives, or heterocyclic compounds which contain at least one benzene nucleus, with nitrogen oxides or their hydrates (other than nitric acid) or mixtures of these, in presence of mercury or mercury compounds, hydroxylated nitro-compounds are obtained. Nitrogen dioxide, nitrogen tetroxide, nitric anhydride, and nitrous acid are suitable for the process.—T. F. B.

Protein substances from anthrax bacilli; Process for obtaining active —. Kalle und Co. Ger. Pat. 214,071, Sept. 17, 1908. Addition to Ger. Pat. 212,830, May 17, 1908 (see this J., 1909, 1062).

THE anthrax bacilli, after treatment with nitrous acid, are heated with dilute alkali, *e.g.*, a 1 per cent. solution of potassium hydroxide, instead of with dimethylamine as described in Ger. Pat. 212,831 (*loc. cit.*), a previous addition to the main patent.—A. S.

1-*Paradiakylaminoaryl-2,4-dialkyl-3-oxymethyl-5-pyrazolone*. F. Stolz and K. Streitwolf, Assignors to Farbwerke vorm. Meister, Lucius, und Brünig, Höchst on Maine, Germany. U.S. Pat. 936,380, Oct. 12, 1909.

SEE Edg. Pat. 4128 of 1909; this J., 1909, 854.—T. F. B.

Lactic acid; Process of making concentrated —. C. H. Boehringer Sohn. Fr. Pat. 401,395, March 29, 1909.

SEE Eng. Pat. 7094 of 1909; this J., 1909, 674.—T. F. B.

Solvents for fats and essential oils. Fr. Pat. 401,704. See XII.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

PATENT.

Cinematograph film; Sensitive —. Soc. Anon. des Plaques et Papiers Photographiques A. Lumière et ses fils. First Addition, dated July 24, 1908, to Fr. Pat. 400,385, June 3, 1908. (See Eng. Pat. 16,114 of 1908; this J., 1909, 491.)

THE film consists of a gelatin film coated with a sensitive emulsion, supported on another film, of some impermeable material the dimensions of which are not altered by the various photographic processes. This insures that the gelatin film, when finally stripped from its support, shall be the same size throughout its length.—T. F. B.

XXII.—EXPLOSIVES, MATCHES, &c.

Explosives; Report of the Chief Inspector (C. N. Hake) of — for the State of Victoria for the year 1908.

THE following table gives the quantities of explosives imported into the State during the years 1907 and 1908:—

	1908.	1907.
	lb.	lb.
Gelignite	752,550	948,900
Gelatin-dynamite	244,250	310,500
Blasting gelatin	104,400	120,300
Cheddite	15,000	15,000
Ripplite	10,000	6,400
Powder fuse	75,000	77,000
Blasting powder	202,125	155,000
Sporting powder	31,050	26,675
Total	1,434,375	1,659,775
Detonators (number)	2,015,000	3,575,800

There were 1026 tests made with explosives. Of these 182 were with blasting gelatin, of which 72 samples were rejected. 509 samples of gelignite were examined and 85 rejected, and 146 samples of gelatin-dynamite, of which 14 were rejected. It is stated that the blasting gelatin imported from European ports was far from satisfactory, over 10 per cent. of the total importations being condemned, partly on account of low stability, and partly owing to the exudation of nitroglycerin. The gelatin-dynamite and gelignite imported during the year were of a very satisfactory nature, all the consignments being passed. All consignments of cheddite complied with the requirements of the Act. The total number of factories under licence was seven, and sixteen Rack-a-rock manufacturing licences

were issued during the year. The total number of magazines under licence was 236, and there were twelve Government magazines available for public use, chiefly for the storage of commercial explosives. No accidents by fire or explosion occurred during the year in the manufacture or transport of explosives.—G. W. McD.

Glycerol ethers; Some nitro-derivatives of —. E. Paternò and T. Benelli. Gaz. chim. ital., 1909, 39, II., 312—314.

THE authors have prepared the nitro-derivatives of the α -dimethyl and α -diethyl ethers of glycerol, obtained by the action of methyl and ethyl alcoholic solutions of potassium hydroxide on epichlorhydrin. The glycerol-ether was allowed to flow drop by drop into a mixture of 100 parts of concentrated sulphuric acid, 20 of concentrated nitric acid, and 30 of anhydrous potassium nitrate, the liquid being kept well stirred, and the temperature kept below 15° C. in the case of the methyl-ether, or 0° C. in that of the ethyl derivative. The reaction product was diluted with water, the oily nitro-derivative separated, washed first with water and then with a dilute solution of sodium carbonate, and purified by distilling with steam in presence of a small quantity of sodium carbonate. The nitro-derivative of the dimethyl ether, $\text{CH}_2(\text{OCH}_3)\cdot\text{CH}(\text{ONO}_2)\cdot\text{CH}_2(\text{OCH}_3)$, is a colourless neutral liquid, soluble in the common organic solvents; it boils at 180° C. and solidifies at about -15° C. It burns readily but is not explosive. A mixture of nitroglycerin (m. pt. -18° C.) with 2 per cent. of the nitro-derivative of the methyl ether melts at -34° C. Ten per cent. of it has no appreciable effect on the sensitiveness of explosion of nitroglycerin. It has a good gelatinising action on nitro-cellulose. Substitution of the nitro-derivative of glycerol-dimethyl ether for the whole or a part of the nitroglycerin in an explosive lowers the ballistic power. The nitro-derivative of glycerol-diethyl ether boils, with decomposition and evolution of heat, at 168°—170° C. When cooled to -75° C. it becomes pasty, but is still mobile at -60° C. —A. S.

INORGANIC—QUANTITATIVE.

Cobalt and nickel; Sanchez' method for separation of —. H. Grossmann. *Z. angew. Chem.*, 1909, 22, 2005—2006.

THE author has subjected Sanchez' method (this J., 1909, 749) to a critical investigation. Sanchez starts with the separation of nickel and cobalt from other metals of the ammonium sulphide group by the use of dilute hydrochloric acid, a method which has been shown to be inexact by Funk (this J., 1906, 954). Next, he assumes that the precipitated nickel and cobalt sesquihydroxides have the composition, Ni_2O_3 and Co_2O_3 , after incineration, whereas the fact is that the precipitates formed in the manner indicated by Sanchez always contain alkali, and the oxides which are stable on strong ignition have the formulæ, NiO and Co_3O_4 . The special feature of Sanchez' method, viz., the separation of the two metals by means of potassium cyanide and silver nitrate, whereby silver cobalticyanide is precipitated, is sound and has been verified by the author, but the subsequent precipitation of the nickel by sodium hydroxide and bromine solution does not yield a pure sesquihydroxide. Bellucci and Clavari have shown that, whatever conditions be chosen, the oxide so obtained always contains either more or less oxygen than would correspond to the formula, Ni_2O_3 . The author concludes that Sanchez' method cannot be preferred to the more rapid and accurate methods of separation based on the use of thiocyanate, dimethylglyoxime and dieryandimidine.—J. F. B.

Arsenic; Irregularities in the volumetric determination of — after previous distillation. [Presence of pyrrole as an impurity in ammonia.] L. Brandt. *Chem.-Zeit.*, 1909, 33, 1114—1115.

IN the determination of arsenic with standard iodine, after previous distillation with strong hydrochloric acid, it is usual to nearly neutralise the distillate with sodium hydroxide or ammonia, before adding sodium bicarbonate. Errors have been detected in both these methods of neutralisation. Sodium hydroxide (even "pure by alcohol") is liable to contain an oxidising agent, which converts part of the arsenious chloride into arsenic acid, causing low results. Ammonia, on the other hand, often contains pyrrole as an impurity, and this combines with iodine: the pyrrole may be detected by boiling the nearly neutralised ammonia, and testing the vapour in the usual way with a pine splinter moistened with hydrochloric acid. It may be destroyed by adding to the ammonia a slight excess of permanganate, and repeating this several times, as the colour disappears; the solution is allowed to stand for 24 hours with frequent shaking, and the hydrated oxide of manganese is then filtered off; ammonia, free from pyrrole and suitable for the determination, is thus obtained. About 5 c.c. of a freshly prepared 2 per cent. solution of pure starch should be used as indicator in the titration.

—F. SODN.

Silica; Separation of — from silicon and carbon. E. Britzke. *Chem.-Zeit.*, 1909, 33, 1098—1099.

SILICA may be separated quantitatively from silicon and carbon (as graphite or as carborundum or iron carbide) by the action of hydrogen chloride gas at a bright red heat, silicon and carbon being converted into volatile products, but the silica remaining unchanged. The hydrogen chloride used must be quite dry. When such mixtures as the above are heated in a current of chlorine, as in Limmer's method (this J., 1908, 121), the carbon is found to remain behind with the silica. A combination of the two methods on different quantities of material is, therefore, suggested for the determination of carbon and silica.—F. SODN.

Earth [niobic and tantallic] acids; Determination of —. L. Weiss and M. Landecker. *Z. anorg. Chem.*, 1909, 64, 65—103.

TANTALIC acid is completely precipitated by carbon dioxide from a solution of the melt obtained by fusing the acid with sodium carbonate and sodium nitrate, whereas the corresponding niobate solution is not decomposed in this way. Niobic acid may also be distinguished from tantallic acid by the fact that no precipitate is obtained, even on standing, when its solution in dilute sulphuric acid is added to concentrated ammonium sulphate. Furthermore, potassium ferrocyanide gives a greyish-green precipitate with a solution of niobic acid in hydrochloric acid, but with tantallic acid a reddish-brown precipitate slowly appears. The best method of distinguishing the two acids, however, is considered to be the microscopic examination of the characteristic crystals obtained, when hydrofluoric acid is added to a solution of a tantalate or niobate which is then neutralised with potassium hydroxide. Several new methods are given for the quantitative separation of niobium, tantalum, and titanium from other metals and from each other, and these have been applied to the analysis of tantalite, the following process being given:—The finely-powdered material is decomposed by fusion with potassium bisulphate, and the cooled melt is extracted with water containing sulphuric acid; to the boiling solution sulphurous acid is added, until the precipitate formed becomes flocculent, and the liquid is kept boiling for 20—30 minutes, which causes all the tin to be precipitated as metastannic acid along with the earth acids. After filtration, the residue is washed with hot sulphurous acid solution containing sulphuric acid, until free from iron, and the filtrate, containing all the elements present in the material, other than niobium, tantalum, titanium, and tin, is dealt with by known methods, after precipitating any remaining tin with hydrogen sulphide. Tin is extracted from the residue of acids, after neutralisation by ammonia, by digestion and subsequent washing with hot yellow ammonium sulphide. The residue is then ignited and fused with sodium carbonate, with the addition of sodium nitrate, no unnecessary excess of either reagent being employed. The melt is extracted with hot water and the liquid boiled for some time, and then filtered from the residue, which contains the titanium. If the filtrate be found free from titanium, it is treated with carbon dioxide to precipitate the tantalum, the gas being passed through the liquid for about 1½ hours in the cold, and the solution then boiled for a short time. If the filtrate contain titanium, it is precipitated with hydrogen sulphide, and the precipitate is dissolved, together with the former titanium residue, in a mixture of sulphuric acid and hydrogen peroxide, the solution being reduced with sulphur dioxide and the titanium precipitated with ammonia. The sodium sulphide in the filtrate, containing tantalum and niobium, is decomposed by sulphuric acid, the earth acids are precipitated with ammonia, and the precipitate again fused with sodium carbonate and sodium nitrate, the melt being dissolved in water and the tantalum precipitated as tantallic acid by a current of carbon dioxide. Before igniting precipitates of niobic, tantallic, and titanic acids, it is recommended that the filter-paper be freed as far as possible from precipitate and moistened with ammonium nitrate. In the event of insoluble sulphates or silver chloride being present with the acids, the latter may be readily separated by dissolving in a mixture of acid and hydrogen peroxide.

—F. SODN.

Phosphorous and hypophosphorous acids; Reducing reactions with, — [and determination of these acids]. A. Sieverts. *Z. anorg. Chem.*, 1909, 64, 29—64.

THE action of phosphorous and hypophosphorous acids on the salts of the heavy metals has been quantitatively studied, both the amount of metal reduced and of acid oxidised being determined. Rupp and Finck's method of determining phosphorous and hypophosphorous acids (this J., 1902, 1473) may be shortened by effecting the oxidation of the hypophosphorous acid by warming in a pressure flask at 70° C. for 30 minutes; the titration of

the excess of iodine is best done with arsenious acid 2 hours after the solution has been rendered alkaline with bicarbonate. For the determination of phosphorous and hypophosphorous acids in the presence of each other, they are first oxidised to phosphoric acid by bromine, and then, in a second sample, they are titrated iodometrically; from the quantity of iodine used, together with that of the phosphoric acid, which is determined gravimetrically, the quantity of each acid present may be calculated. It is noted that these acids suffer no appreciable oxidation on exposure to air, being remarkably stable towards many oxidising agents. Gold and silver salts are reduced to the metal by phosphorous or hypophosphorous acid, no hydride being formed. Silver is deposited first as a black precipitate which probably contains colloidal silver. Copper sulphate is reduced by phosphorous acid to metallic copper, but cupric chloride is reduced to the cuprous salt. Hypophosphorous acid reduces copper sulphate in excess to the metal, without the evolution of hydrogen, but, if the acid be in excess, copper hydride is precipitated, though mixed with metallic copper. Platinum chloride is not reduced by hypophosphorous acid; palladium chloride, however, is reduced in the cold, both by this and by phosphorous acid. Nickel and cobalt salts are not reduced by either acid. The freshly precipitated palladium, copper, gold, and silver act catalytically on the excess of hypophosphorous acid, according to the equation: $\text{H}_2\text{PO}'_2 + \text{H}_2\text{O} = \text{H}_2\text{PO}'_3 + \text{H}_2$, but platinum black has no such action, although nickel and cobalt, reduced from their oxides by hydrogen at $320^\circ\text{--}330^\circ\text{C.}$, are very effective. Palladium is the best catalyst, acting at the ordinary temperature, and cobalt and nickel come next in activity; gold, silver, and copper act but slowly at 100°C. Finely-divided iron is rapidly dissolved by hypophosphite solutions.—F. SODN.

Carbon monoxide; Determination of —, in mine gas. E. H. Weiskopf. J. Chem. Met. and Min. Soc., S. Africa, 1909, 9, 258—265, 306—307.

IN connection with a paper by Cullen on the nature of the gases resulting from the use of high explosives (this J., 1909, 162), the method employed for the determination of the carbon monoxide is now described. The process consists in the use of iodine pentoxide, which reacts with carbon monoxide, producing free iodine and carbon dioxide, thus: $\text{I}_2\text{O}_5 + 5\text{CO} = \text{I}_2 + 5\text{CO}_2$. The applicability of this reaction for the estimation of traces of carbon monoxide was originally demonstrated by Nieloux (Comptes rend., 1898, 126, 746). After being freed from moisture, carbon dioxide and unsaturated hydrocarbons or other interfering constituents, the gas passes through an absorption coil containing iodine pentoxide kept at 150°C. by immersion in an oil bath. The vapour of the liberated iodine is absorbed in potassium iodide solution and subsequently titrated with thiosulphate. The fact that unsaturated hydrocarbons are also oxidised by iodine pentoxide with liberation of iodine is specially emphasised, as also is the difficulty of their complete absorption by the usual reagents. The absorbent used for this purpose in the present instance, and which was found to be very efficient, consisted of strong sulphuric acid (99 to 99.5 per cent. H_2SO_4) kept at 165°C. Figures and data involved in the analysis of samples of mine gas, taken before and after blasting with gelignite, are appended, while the origin of the carbon monoxide itself is also discussed.—W. E. ORGANIC—QUALITATIVE.

Blood; Value of benzidine for the detection of minute traces of —. E. J. McWeeney. Roy. Dublin Soc. Proc., 1909, 12, 216—224.

SCHLESINGER and Holst (Deutsch. med. Wochenschr., 1906) have drawn attention to the value of benzidine for the

detection of traces of blood in faecal matter. The author finds that a solution of benzidine in acetic acid at once produces a blue coloration with a 1 in 200,000 solution of blood in presence of hydrogen peroxide: in absence of blood, no colour develops for about two minutes. Dried blood in particulate form from stains, etc., is very readily detected by this means, and its reaction is quite distinct from that of other body-fluids. Similar reactions are given by many freshly cut vegetables, but after boiling, no reaction takes place, whereas blood solutions react equally well after ten minutes' boiling.—T. F. B.

ORGANIC—QUANTITATIVE.

Aliphatic acids; Separation of mixtures of some — by means of benzene and toluene. T. R. Hodgson. Analyst, 1909, 34, 435.

LASSERRE (Ann. de l'Institut Pasteur, 1907, 829) devised a method of separating formic and acetic acids from butyric, valeric, iso-valeric acids, etc., by extracting the aqueous solution of the mixed fatty acids with benzene. The formic and acetic acids were said to remain in the aqueous layer, whilst the higher acids were removed by the benzene. The author's experiments with weighed quantities of the pure fatty acids indicated that the separation thus effected was incomplete, and that the amount of error varied with the quantity of acids, the proportion of volatile solvent used, and the number of extractions. Similar results were obtained when toluene and light petroleum spirit were used for the extraction. By working under constant conditions, however, the method may in some cases be found useful. The best results are obtained when the aqueous solution of the fatty acids is extracted with twice its volume of benzene.—C. A. M.

Aliphatic acids; Separation of mixtures of some — by means of benzene. C. A. Keane and P. Narracott. Analyst, 1909, 34, 436—438.

IN the authors' experiments to test the reliability of Lasserre's method of separation (see preceding abstract), determinations were made of the ratio of distribution of the acids between water and benzene. Where the proportion of benzene to aqueous solution was as 1:1, the solubility of isovaleric acid in benzene was only about 100 times greater than that of formic or acetic acids. By using a larger proportion of benzene to water (10:1), a somewhat better separation was effected, whilst when the water was in large excess (1:10) similar differences of solubility were observed, but isovaleric acid was only about 200 times more soluble than acetic acid in the benzene. The ratio of distribution between the two solvents varied with the concentration of the different acids, although it was maintained in a mixture of acids. In the authors' opinion Lasserre's method does not afford a satisfactory means of separation.—C. A. M.

XXIV.—SCIENTIFIC & TECHNICAL NOTES.

Colloidal solutions of metals obtained by the action of boiling distilled water. M. Traube-Mengarini and A. Scala. Atti R. Accad. dei Lincei, Roma, 1909, [5], 18, II., 111—116. Chem. Zentr., 1909, 2, 1411—1412. (See this J., 1909, 857.)

By repeatedly boiling the purest water in a silver dish containing pieces of silver, and then concentrating, solutions containing up to 0.0162 grm. of silver per 100 c.c. were obtained. Similar experiments in a platinum dish gave a solution of a faint greenish colour, which contained in colloidal solution mostly copper and copper oxide, but also traces of platinum; traces of platinum were also dissolved in a similar manner from a platinum dish, but only with great difficulty. In commercial "platinum solutions," prepared by the electrical process, the authors were able to detect considerable quantities of copper, but could not with certainty detect platinum.—A. S.

Chemical accidents: First aid in —. Nobel's Explosives Company, Ltd. Chem. Trade J., 1909, 45, 358.

Sulphuric and nitric acid burns.—Acid burns are sometimes very deceptive as to their severity, especially those from nitric acid. This acid causes a yellowish stain on the skin, which has a peculiar parchment-like feeling to the touch. The burn is apt to be made light of at first, but in a few days a red line, denoting inflammation, begins to form round the yellowish patch, following which separation of the slough commences, which takes a con-

siderable time and leaves a raw, granulating surface, slow in healing. If it is not carefully attended to, so as to keep the granulation down, it will leave a prominent scar and permanent disfigurement.

Treatment.—In all cases of severe burns, either from nitric or sulphuric acids, the patient should at once be plunged into the usual tank containing water and bicarbonate of soda; then the part should be thoroughly bathed with pure warm water, afterwards applying a cloth saturated with oil, and then covering with cotton wool and a bandage. The patient should be taken at once to his home or to an hospital. Then commences the proper treatment of the burn, which is suitable for both nitric and sulphuric acid burns. A piece of surgeon's lint saturated with carron oil (equal parts of linseed oil and lime-water) is applied, the smooth surface of the lint being placed to the part, and is covered with oiled silk or gutta tissue, cotton wool or gamgee and absorbent bandage. This dressing should be changed night and morning for the first few days, but should the burn be very severe and painful, then a thin piece of cotton cloth saturated with carron oil, and a warm bread-and-water poultice are applied, covered as before with wool or gamgee and a bandage. The poultices should be renewed at least two or three times in the 24 hours and continued until the separation of the slough, when the carron oil G.P. tissue dressings are reverted to, as at first. Should the burn become irritable and slow in healing then carbolic oil, borie lint, or the following paste may be tried, according as is found suitable. Paste—composed of equal parts, by weight, of carron oil and zinc oxide ointment. Should the granulations become exuberant or above the level of the surrounding skin, they should be painted over with a two per cent. solution of cocaine, before being touched, every second day, with a solution of nitrate of silver (15 to 20 grs. to the ounce of distilled water), or with solid lunar caustic, afterwards being dressed with carbolic or carron oil, as before.

Acid burns of eyes.—Acid burns of the eyes should on no account be bathed with alkaline solutions, but at once and liberally, with pure warm water, or warm water and milk, allowing the fluid to run freely over the eyeballs. Afterwards a few drops of a two per cent. solution of cocaine hydrochloride, slightly warmed, are applied, then a little pure castor oil, and lastly, a piece of lint saturated with warm water is placed over the eye and held there by means of a light bandage. This can be repeated two or three times a day. Cocaine alkaloid dissolved in castor oil is sometimes used, but the first method is best. A two per cent. ointment of cocaine hydrochloride and vaseline applied to the eyelids, affords great relief, and should be applied at bed-time. In using the cocaine solution, a good plan is to warm a teaspoon in hot water, thus making the application more agreeable to the injured eye. This treatment should be continued for a few days, but the after-treatment must depend entirely upon the severity of the burn.

Books Received.

UEBER DIE ERHALTUNG DER MASSE BEI CHEMISCHEN UMSETZUNGEN. [Abhandlungen der deutschen Bunsen-Gesellschaft für angewandte physikalische Chemie.] No. 1. Von H. LANDOLT. Wilhelm Knapp's Verlag. Halle a. S. 1909. Price M1.80.

8vo volume, containing 47 pages of subject matter.

BEITRÄGE ZUR KENNTNISS DES ELEKTROCHEMISCHEN VERHALTENS DES EISENS. [Abhandlungen der deutschen Bunsen-Gesellschaft für angewandte physikalische Chemie.] No. 2. Von F. FOERSTER. Wilhelm Knapp's Verlag. Halle a. S. 1909. Price M3.20.

8vo volume, containing 83 pages of subject matter and six illustrations. The subjects of the various chapters

are:—I. Experiments on the equilibrium potential of iron. II. Active iron. III. Theoretical considerations. (i). The views hitherto entertained as to the passive condition of iron. (ii). Hydrogen content of iron, and the active condition of the metal. (iii). Variation of the potential of active iron. (iv). The spontaneous activation of iron. (v). Disturbances of the spontaneous activation by oxide incrustations. (vi). Activation by halogens, &c. (vii). General remarks. IV. Electrolytic separation of iron. V. Electrolytic iron.

CHEMICAL CONVERSION TABLES. For use in the analysis of Fertilisers, Fertilising material, Cotton seed, Iron and its products, Food products, &c. By H. B. BATTLE, Ph.D., Montgomery, Ala. and W. J. GASCOYNE, Ph.D., Baltimore, M.D. Williams and Wilkins Publishing Company, Baltimore, Md. 1909. Price \$2.50.

SMALL Svo volume, containing 13 tables, arranged for immediate and ready reference, by means of projecting portions of each table, in step-like order as in the index of a ledger; each of these projections containing the title of the table indexed. Thus:—Tables of, I. Phosphoric acid. II. Potash. III. Ammonia and protein. IV. Nitrogen weight. V. Chlorine. VI. Sulphur. VII. Alumina. VIII. Phosphorus and magnesia. IX. Silicon. X. Manganese. XI. International atomic weights, 1909. XII. Conversion factors. XIII. Weights and measures.

PRACTICAL POINTS FOR PRACTICAL BREWERS. A Reference Book for all interested in the Arts of Brewing and Malting. Compiled by the staff of the National Brewers' Academy. Editors: FRANCIS WYATT, EMIL SCHLICHTING. The National Brewers' Academy and Consulting Bureau, New York. 1909. Price 6s. 3d., or \$1.50 net.

SMALL volume of pocket book size and shape, and containing 159 pages of matter. There is an alphabetical index of subjects. The matters treated of are as follows:—I. Instructions for taking and sending samples. II. Permissible limits for differences in analytical results. III. Table with composition of certain water supplies in the United States. IV. Scheme for examination of water for brewery use. V. Practical points on malting barleys, &c., and on malt kilning. VI. Malt adjuncts. VII. Comparative table of brewing value of various cereal products. VIII. Brewing sugars. IX. Practical points on hops. X. American beers, &c. XI. General points on the mashing process for lager beers. XII. Chief points in brewing ales and porters. XIII. Causes of loss in brewery operations. XIV. Points on refrigeration. XV. Micro-organisms. XVI. Moulds. XVII. Bacteria. XVIII. Cultivated yeasts. XIX. Beer turbidities. XX. Antiseptics and cleaning agents. Also series of tables, statistics, constants, weights and measures, &c.

A MANUAL OF FORENSIC CHEMISTRY DEALING ESPECIALLY WITH CHEMICAL EVIDENCE, ITS PREPARATION AND ADDUCTION. Based upon a course of lectures delivered at University College, University of London. By WILLIAM JAGO, Stevens and Haynes, Bell Yard, Temple Bar, London. 1909. Price 5s. net.

Svo volume, containing 252 pages of subject matter, and an alphabetical index of subjects. The matter in this work is classified and arranged in the following chapters:—I. Introductory, defining nature of chemistry; of forensic chemistry; evidence; burden of proof; chemical evidence, &c. II. Adulteration of food. III. Adulteration of drugs. IV. Use or non-use of new manufacturing processes. V. Use of preservatives and colouring matters. VI. More important criminal matters. VII. Chemical evidence in civil actions. VIII. Practice. (i). Proceedings under Food and Drugs Act. (ii). Meaning of *prima facie* evidence. (iii). Precautions by analyst, and by solicitor. (iv). Reference to "Somerset House." (v). Example of ruling in civil action, &c.

CHEMISTRY IN DAILY LIFE. Popular Lectures by Dr. LASSAR-COHN, Professor in the University of Königsberg. Translated by M. M. PATTISON MUIR, M.A. Fourth edition, revised and augmented. H. Grevel and Co., 33, King Street, Covent Garden, London, W.C. 1909. Price 6s. net.

Svo volume, containing 295 pages of subject matter, with 25 illustrations, and an alphabetical index of subjects. The subject matter is classified as follows:—I. Breathing. Weight of the air. Analysis of air. Combustion.—Matches. II. Nature of flame. Candles. Cooking by gas. Electric furnace. Acetylene. III. Food of plants. Manuring fallow land. Artificial manures. Food and foodstuffs. IV. Mixed diet. Butter. Margarin. Starch. The sugars, &c. V. Quantity of food necessary, and nutritive values of the chief foods. Fermentation. Wine. Cider. Beer, spirits. Absolute alcohol, &c. VI. Wine vinegar. Wood vinegar. Glacial acetic acid. Wood spirit. Acetone. Explosives. Wool, cotton, silk, &c. VII. Tanning. Leather. Parchment. Bleaching. Antichlor. Dyeing. Mordants. Lakes. Substantive colours, &c. Calico printing. VIII. Oil painting. Drying and non-drying oils. Varnishes. Inks. Cellulose. Paper, &c. IX. Potash. Soda. Sulphuric acid, alkalis, &c. X. Glass. Photography. The X rays. Radio-activity.—Radium. XI. Noble and base metals. Ores. XII. Alloys. Alkaloids, &c.

LABORATORY NOTES ON IRON AND STEEL ANALYSES. By WALTER MACFARLANE. Longmans, Green, and Co., 39, Paternoster Row, London; also New York, Bombay, and Calcutta. 1909. Price 7s. 6d.

Svo volume, containing 450 pages of subject matter, with 25 illustrations, and an alphabetical index of subjects. The grouping of the subjects proceeds as follows:—I. ANALYSIS OF STEEL. Determination of (i), combined carbon. (ii), silicon. (iii), phosphorus. (iv), manganese. (v), sulphur. II. ANALYSIS OF PIG IRON. Determination of combined carbon, graphitic carbon, silicon, phosphorus, manganese, sulphur, carbon, iron, chromium, chromic oxide, nickel, arsenic, aluminium, copper, tungsten, vanadium, molybdenum. III. Analysis of quick-cutting tool steel. IV. Analysis of alloys used in making quick-cutting steel. V. Analyses of (i), tungsten powder. (ii), iron ores. (iii), clayband ironstone. VI. Determination of lead, copper, and zinc in ores. VII. Analyses of iron ores requiring treatment with fusion mixture. Analyses of hematite ore, limestone, calcined limestone, dolomite, blast furnace slags, puddler's cinder, flue cinder, &c., basic slag. VIII. Miscellaneous determinations. IX. Notes on sampling. X. General notes on laboratory operations, &c. XI. Baumann's auto-sulphur printing method. XII. Blast furnace calculations. XIII. United States Steel Corporation methods for ore analysis. XIV. Cushman's method of comparing rate of corrosion.

PHILIPPINE ISLANDS. NEW CUSTOMS TARIFF. [Cd. 4903.] Wyman and Sons, Fetter Lane, London, E.C. Price 6ld.

THIS is a copy of the Act of United States Congress, approved August 5th, 1909, giving the new Customs tariff of the Philippine Islands, together with the rates of duty formerly in force.

RECENT ADVANCES IN PHYSICAL AND INORGANIC CHEMISTRY. By A. W. STEWART, D.Sc. With an introduction by Sir WM. RAMSAY, K.C.B., F.R.S. Longmans, Green, and Co., 39, Paternoster Row, London; also New York, Bombay, and Calcutta. 1909. Price 7s. 6d.

Svo volume, containing 250 pages of subject matter, and alphabetical indexes of names of authors and investigators, and of subjects. There are 25 illustrations. The text is classified as follows:—I. Some hydroxylamine derivatives. II. Colloids. III. Reactions in liquid ammonia. IV. Fixation of nitrogen. V. Double salts.

VI. The problem of the oceanic salt deposits. VII. The cobaltamines. VIII. Absorption spectra. IX. The elements of the rare earths. X. Atomic weights. XI. The inactive gases. XII. The radioactive elements. XIII. Radioactive changes. XIV. Radioactive emanations.

REVIEW OF THE TRADE OF INDIA IN 1908-9. [Cd. 4912.] Wyman and Sons, Fetter Lane, E.C. Price 1s. 3d.

COLONIAL IMPORT DUTIES, 1909. Return relating to the Rates of Import Duties levied upon the principal and other articles imported into the British Colonies, Possessions, and Protectorates. [Cd. 4874.] Price 2s. 9d. Wyman and Sons, Fetter Lane, E.C.

Patent List.

Where a Complete Specification accompanies an Application, an asterisk is affixed. The dates given are (i) in the case of Applications for Patents, the dates of Application, and (ii) in the case of Complete Specifications Accepted, those of the Official Journals in which acceptances of the Complete Specifications are advertised. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

I.—PLANT, APPARATUS, AND MACHINERY.

APPLICATIONS.

23,534. Siemens. Regenerative gas re-heating furnaces.* Oct. 14.

23,552. Schroder. Cooling or drying apparatus. [Ger. Appl., Oct. 15, 1908.]* Oct. 14.

23,846. Ward. See under XXIII.

23,864. Dieker (Maschinenbau A.-G. Gölzern-Grimma). Liquid vaporising or concentrating apparatus. Oct. 18.

23,866. Lindahl. See under X.

23,869. Raab. Heating or evaporating solids or liquids. [Ger. Appl., Sept. 30, 1909.]* Oct. 18.

23,975. Phillips and Bulteel. Accelerating chemical changes in mixtures of solids and vapours or gases. Oct. 19.

23,978. Tixier. Filters for liquids or gases. [Fr. Appl. Oct. 21, 1908.]* Oct. 19.

24,074. Morison. Apparatus for heating and evaporating liquids. Oct. 20.

24,402 and 24,403. Arbuckle and Osborne. Separating comminuted solid matter such as pulverised ore from liquids.* Oct. 23.

24,458. Simpson. Apparatus for distilling volatilisable solids and for heating and separating gases *in vacuo*. Oct. 25.

24,465. Keyser. Heating drums. [U.S. Appl. Nov. 6, 1908.]* Oct. 25.

24,540. Spence, and Spence and Sons, Ltd. Preparation of comminuted solids. Oct. 26.

24,665 and 24,666. Robinson (Massey-Harris Co.). Centrifugal separators.* Oct. 27.

24,805. Johnson (Koepp und Co.). Absorption of gas from a mixture of gases by hot liquor. Oct. 28.

COMPLETE SPECIFICATIONS ACCEPTED.

13,588 (1908). Groth. Storage vessels for liquefied gases. Oct. 20.

15,683 (1908). Feld. Subjecting gases to the action of liquids. Nov. 3.

21,767 (1908). Cudlipp. Centrifugal hydro-extractors. Oct. 27.

22,118 (1908). Lang. Heating materials by the heat developed on formation of metallic sulphides. Oct. 27.

23,189 (1908). Wilfley Mining Machinery Co., and Rondebush. Apparatus for separating solids from liquids. Oct. 20.

27,000 (1908). Bovone. Kilns. Nov. 3.

27,551 (1908). Snowden. Kilns. Nov. 3.

1151 (1909). Thompson (Badische Maschinenfabr. u. Eisengiesserei). Separating substances of different specific gravities. Nov. 3.

1716 (1909). Sacro. Manufacture of filters. Oct. 27.

4325 (1909). Marks (Jahn-Kommanditges.). Centrifugal separating apparatus. Oct. 20.

6167 (1909). Ernst. Process of cleaning gases. Oct. 20.

8621 (1909). Streller. Rendering organic and inorganic bodies transparent or translucent. Nov. 3.

II.—FUEL, GAS, AND LIGHT.

APPLICATIONS.

23,171. Gebr. Siemens und Co. Manufacture of arc light electrodes. [Ger. Appl., Nov. 19, 1908.]* Oct. 11.

23,434. Visseaux. Manufacture of incandescent mantles.* Oct. 13.

23,555. Graigola Merthyr Co., Ltd., Yeo, and Goskar. Manufacture of artificial or patent fuel. Oct. 14.

23,624. Williams. Removing cyanogen from coal gas, etc. Oct. 15.

23,671. Müller. Manufacture of coke and gas.* Oct. 15.

23,709. Clarkson and Behrmann. Manufacture of briquettes from peat-bog.

23,760. Oligny, and Peat Gas and Coal Co. Peat gas producing process. Oct. 16.

23,767. Oligny, and Peat Gas and Coal Co. Peat gas plants.* Oct. 16.

23,810. Goldstein. Manufacture of absorbent coal. [Addition to No. 17,914 of 1909. Ger. Appl., Aug. 6, 1909.]* Oct. 18.

24,014. Du Thil. Gas producers.* Oct. 19.

24,030. Fielding and Eady. Apparatus for purifying and washing gas. Oct. 20.

24,261. Burstall. Apparatus for separating suspended matter from gases.* Oct. 22.

24,353. Lessing. Carbonisation of coal. Oct. 23.

24,443. Muller and Bonnet. Manufacture of incandescent mantles. [Addition to No. 6555 of 1909. Fr. Appl., Nov. 3, 1908.]* Oct. 25.

24,725. Sheldon. Gas producers.* Oct. 27.

25,018. Graf and Smyth. *See under X*.

25,019. Richards and Pringle. Distilling or partially distilling coal for the production of fuel. Oct. 30.

25,036. Baker. Apparatus for making gas. Oct. 30.

COMPLETE SPECIFICATIONS ACCEPTED.

21,763 (1908). Burkheiser. Purifying gases generated by dry distillation and obtaining by-products. Oct. 27.

22,851 (1908). Tully. Gas producer apparatus. Nov. 3.

24,803 (1908). Tully. Gas producers. Nov. 3.

25,736 (1908). Temple. Washing or purifying apparatus for gas generating plants. Oct. 20.

28,201 (1908). Dempster and Sons, and Toogood. Vertical retorts. Oct. 27.

1630 (1909). Milbourne. Gas purifiers. Nov. 3.

1937 (1909). Dempster and Sons, Ltd., and Brooke. Gas retorts. Oct. 20.

6167 (1909). Ernst. *See under I*.

7092 (1909). Heinrich. Manufacture of electric incandescent filaments of refractory metals or their alloys. Oct. 27.

7615 (1909). Pieph. Production of gas for lighting, heating, and power-producing. Oct. 27.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

APPLICATIONS.

23,348. Wohle. Petroleum and other hydrocarbon oils. Oct. 12.

23,766. Hugendick. Continuous distillation of tar. [Ger. Appl., Oct. 16, 1908.]* Oct. 16.

23,977. Phillips and Bulteel. Production of light oils from heavier mineral oils. Oct. 19.

24,216. Roesch (Burchard). Treating oil and petrol for lighting, heating, and other purposes. Oct. 21.

COMPLETE SPECIFICATIONS ACCEPTED.

21,800 (1908). Gutensohn. Treatment of tar. Oct. 27.

22,853 (1908). Reilly. Purification of tar. Oct. 27.

IV.—COLOURING MATTERS AND DYESTUFFS.

APPLICATIONS.

23,181. Johnson (Badische Anilin und Soda Fabrik). Manufacture of halogen derivatives of indigo. Oct. 11.

23,204. Newton (Bayer and Co.). Manufacture of azo dyestuffs. [Addition to No. 1397 of 1909.] Oct. 11.

23,532. Bloxam (Act.-Ges. f. Anilinfabr.). Manufacture of azo dyestuffs and pigment colours therefrom. Oct. 14.

23,738. Bloxam. (Act.-Ges. f. Anilinfabr.). Manufacture of monoazo dyestuffs for chrome mordanted wool. Oct. 16.

23,873 and 23,874. Johnson (Badische Anilin und Soda Fabrik). Reduction of indigo and similar colouring matters. Oct. 18.

23,875. Johnson (Badische Anilin und Soda Fabrik). Manufacture of vat colouring matter. Oct. 18.

23,992. Levinstein, and Levinstein, Ltd. Manufacture of azo dyestuffs. Oct. 19.

24,487. Newton (Bayer and Co.). Manufacture of acid wool dyestuffs. Oct. 25.

24,703. Bloxam (Act.-Ges. f. Anilinfabr.). Manufacture of sulphurised dyestuffs. Oct. 27.

24,920. Meister, Lucius, und Brünig. Manufacture of dyestuffs of the anthraquinone series. [Ger. Appl. Feb. 1, 1909.]* Oct. 29.

COMPLETE SPECIFICATIONS ACCEPTED.

1244 (1909). Johnson (Badische Anilin und Soda Fabrik). Manufacture of colouring matters of the pyrazolone group. Oct. 27.

1920 (1909). Fowler. *See under V.*

2609 (1909). Imray (Meister, Lucius, und Brünig). Manufacture of greenish-blue hexabromindigo. Nov. 3.

5382 (1909). Newton (Bayer and Co.). Manufacture of derivatives of the anthracene series. Nov. 3.

5786 (1909). Newton (Bayer and Co.). Manufacture of dyestuffs of the anthraquinone series. Oct. 20.

10,666 (1909). Ges. f. Chem. Ind. in Basel. Manufacture of green vat dyestuffs. Oct. 27.

10,936 (1909). Imray (Soc. Chem. Ind. in Basel). Manufacture of substantive azo dyestuffs. Oct. 20.

12,371 (1909). Mesiter, Lucius, und Brünig. Manufacture of disazo dyestuffs. Oct. 20.

14,315 (1909). Imray (Soc. Chem. Ind. in Basel). Manufacture of substantive tetrazo dyestuffs. Oct. 27.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

APPLICATIONS.

23,422. Westbrook and Biggs. Rendering cotton, woollen, and other material waterproof. Oct. 13.

23,428. Levinstein, and Levinstein, Ltd. Production of multi-coloured effects on woollen goods. Oct. 13.

23,437. Malard. Treatment by liquid processes of textile and other materials. [Addition to No. 759 of 1908.]* Oct. 13.

23,547. Friedlander and Tuebben. Providing linen, &c., with a washable coating. [Ger. Appl. March 15, 1909.]* Oct. 14.

23,637. Bradford Dyers' Assoc., and others. Apparatus for printing textile fabrics. Oct. 15.

24,006. Zimmer. Waterproofing and glazing linen and other textile articles. Oct. 19.

24,198. Borrel. Dyeing and printing woven materials. Oct. 21.

24,217. Green. Production of aniline black on textile fibres and fabrics. [Addition to No. 16,189 of 1907.]* Oct. 21.

24,404. Schumacher and Resch. Apparatus for dyeing wound yarn. [Fr. Appl. Oct. 24, 1908.]* Oct. 23.

Meeting held at Burlington House on Monday, November 1, 1909.

DR. J. LEWKOWITSCH IN THE CHAIR.

ON NAPHTHALENE PICRATE AND THE QUANTITATIVE DETERMINATION OF NAPHTHALENE.

BY W. P. JORISSEN AND J. RUTTEN.

In the course of a large number of determinations of naphthalene by the Colman-Smith method,¹ the results obtained were always too low.² In these experiments coal gas freed from naphthalene or air was passed together with naphthalene through U-tubes containing picric acid solution, which were weighed before and after the experiment. Niermeyer³ obtained similar results independently. When it was attempted to determine the picrate formed by filtering, washing with water, and drying in a desiccator, the results were lower still: 82 per cent. of the naphthalene *in maximo*. It was, however, observed that accurate results were obtained when the washing bottles contained not only a saturated solution of picric acid, but some undissolved picric acid as well. The method used⁴ was as follows: 250 c.c. of a saturated solution of picric acid is evaporated to about 150 c.c., and transferred whilst hot to two gas-washing bottles. The coal gas, which has been freed beforehand from tar, cyanogen, hydrogen sulphide, and ammonia, is passed through the bottles at a rate of 30–40 litres an hour. When a fair quantity of picrate has been formed in the first bottle, the gas-meter is read and the picric acid solution together with the picrate are transferred to a 250 c.c. flask. The bottles are washed with water, which is added to the solution, and the latter is made up to 250 c.c. with water and heated in the closed flask for half an hour at 40° C., and shaken from time to time, in order to dissolve the picric acid.

The cooled solution is filtered and 25 c.c. of the filtrate are titrated by a solution of potassium hydroxide of known strength, using litmus as indicator; 25 c.c. of the original solution are also titrated. From the difference, the quantity of absorbed naphthalene may be easily calculated.

The results obtained were as follows:—

Naphthalene found by weighing the U-tube.	Naphthalene found by titration.
mgrs.	mgrs.
147	145
158	154
139	141
215	217
389	383

The fact that it is necessary to have enough undissolved picric acid in the gas-washing flasks is explained by the phase rule. Picric acid, naphthalene picrate, naphthalene, and the saturated solution cannot be in equilibrium with each other at the same time; hence, if there is equilibrium between the saturated solution, picric acid, and naphthalene picrate, any naphthalene which is added is transformed into naphthalene picrate as long as picric acid crystals are present.

If the method was to give good results, it was necessary that the picrate should be practically insoluble in a saturated solution of picric acid. This was found to be the case. 100 c.c. of water were shaken for some weeks

with 5 grms. of picric acid and 2.5 (in other exp. 5) grms. of naphthalene picrate at a temperature of 25° C. A large thermostat was used, which was kept at a constant temperature by means of a toluene regulator. The precipitate was then allowed to collect at the bottom of the bottles, and part of each solution was drawn off and weighed. After heating with excess of a solution of sodium hydroxide of known strength (about decinormal), the remaining sodium hydroxide was titrated by means of sulphuric acid (about decinormal), using phenolphthalein as indicator. The strength of the sodium hydroxide solution was tested by means of pure picric acid.

For the determination of the naphthalene, some 10 per cent. sodium hydroxide solution was added to weighed quantities of the solutions; the separated naphthalene was filtered off into a small tube containing asbestos (which had been heated beforehand, in order to remove traces of organic matter). After washing with water, the small tube was placed in a combustion tube partly filled with copper oxide, and the naphthalene was decomposed in a stream of pure oxygen. The carbon dioxide formed was absorbed as usual and weighed. In this way it was found that 100 grms. of the solution contained 1.44 grms. of picric acid and 0.0027 gm. of naphthalene. Some experiments were made with pure naphthalene picrate in order to verify these results; the weighed quantity of the substance was treated with sodium hydroxide, the naphthalene was filtered off and was decomposed as in the experiments described above.

Naphthalene picrate.	Carbon dioxide produced.	Naphthalene calculated from the carbon dioxide.	Naphthalene calculated from the picrate.
mgrms.	mgrms.	mgrms.	mgrms.
41.1	48.8	14.2	14.7
56.1	65.1	19.0	20.1

Naphthalene is practically insoluble in water; in 100 grms. of the saturated solution of picric acid and naphthalene picrate about 3 mgrms. are found. As the solutions used in Rutten's method are not saturated at the moment when they are filtered, the inaccuracy caused by the solubility of the naphthalene is very small.

Solubility experiments were also made at the same temperature (25° C.) with picric acid alone, and with naphthalene picrate and naphthalene. It was found that 100 grms. of the saturated solution of picric acid dissolved 1.33 grms. of this substance.⁵ In 100 grms. of the solution, which is in equilibrium with naphthalene picrate and naphthalene 0.183 gm. of picric acid and a trace of naphthalene are present.

In consequence of this, the "solubility" of the naphthalene picrate observed by Colman and Smith, who found that 100 c.c. of water at a temperature of 14° dissolve 0.1857 gm. of "naphthalene picrate," is to be interpreted in a somewhat different manner. The decomposition of naphthalene picrate by water, which is a great drawback in using the method of Colman and Smith, had already been observed some 50 years ago by Fritzsche.⁶ He stated that the crystals were superficially decomposed when treated with cold water. On boiling the solution with water it was found that naphthalene distilled with the water vapour. That the picrate can be recrystallised from a weak solution of picric acid, is shown by the diagram obtained when the results of the solubility determinations are plotted in a triangle after the manner of Schreinemakers, when treating three component systems. From this diagram, which we reproduced elsewhere⁷, various other conclusions can be drawn.

⁴ Rutten, Ibid., 1908, 449.

⁵ Marchand (Jahresb., 1847, 48, 539), found 1.21 grms. at 20° and 1.36 grms. at 26° C.

⁶ J. prakt. Chem., 1858, 73, 285.

⁷ Chem. Weekblad, 1909, No. 16.

Paternò and Nasini,⁸ who determined the freezing point of solutions of naphthalene picrate in acetic acid, found that in dilute solutions it is almost completely dissociated into naphthalene and picric acid. Anschütz⁹ observed the same in benzene solutions. In order to ascertain whether this is also the case in alcoholic solutions, we determined the boiling point of such solutions, using Landsberger's apparatus.¹⁰ Solutions which contained 5.68 grms. and 11.67 grms. of naphthalene picrate in 100 grms. of absolute alcohol, showed elevations of the boiling point of 0.345° and 0.650° C. From these data the molecular weights 189 and 206 are calculated. As half of the molecular weight of the picrate is 179, it follows that in alcoholic solution too the decomposition is considerable and increases with the dilution.

These experiments were made in connection with the method of Stavorinus¹¹ for the determination of naphthalene in coal gas. The gas is passed through glacial acetic acid, and the dissolved naphthalene is precipitated again by diluting or by neutralising the acid. After filtration through a filter, drying at 100° C., and washing with water, the naphthalene is put into a small crystallising vessel, containing 5 grms. of picric acid and 50 c.c. of strong alcohol. The solution is evaporated on a water-bath, and the remaining substance is dried till the weight does not change any more. After heating on the water-bath for 6 or 10 hours, and even after having added another 50 c.c. of alcohol, the weight of the residue was stated by Stavorinus to remain constant. Now Nierneyer and also Rütten observed considerable decrements of this weight. The latter observed the same at a temperature of 60°. Our observations on the decomposition of the picrate in alcoholic solutions offer an explanation for the observed evaporation of naphthalene during that of the alcohol. Also on heating the pure dry picrate at a temperature of 100° for some days we found that the naphthalene is totally evaporated (also traces of the picric acid; the vessel is coloured yellow).

DISCUSSION.

Mr. C. J. D. Gair said the figures placed on the board showing the accuracy of the new method were very little more in accord with one another than similar figures found with Dr. Colman's own test. There was nothing particularly wrong with any well-known test for the estimation of naphthalene in coal gas, if care were taken to see that the naphthalene was entirely converted into naphthalene picrate, and not left as naphthalene plus naphthalene picrate. If the gas to be tested was passed into acetic acid, as suggested by himself in a former paper (this J., 1907, 1263), the naphthalene went completely into solution and could be precipitated as pure naphthalene picrate by the addition of picric acid solution in excess. In the naphthalene test lacmoid indicator was generally used, but he had not found that an ideal indicator. He considered that phenolphthalein gave a much sharper and more delicate end reaction.

Dr. H. G. COLMAN said that in their original paper Colman and Smith had pointed out that the precipitate of naphthalene picrate must only be slightly washed with water, as otherwise the results came out too low, for the reasons mentioned by the author. In his present practice, he avoided washing the picrate altogether, the naphthalene picrate solution, after heating and subsequent cooling, being poured into a measuring cylinder, its volume noted, and then filtered through a dry filter paper, the first few c.c. of the filtrate being rejected as these are weaker than the rest. 100 c.c. or more of the remainder of the filtrate was then titrated with $N/10$ soda in the usual manner, and from the result, and the total volume of the solution, the amount of picric acid in the whole solution was readily

calculated. A slight error was introduced as the naphthalene picrate crystals were measured along with the liquid, but the magnitude of the error was very small.

Nottingham Section.

Meeting held at Nottingham on Wednesday, October 27th, 1909.

MR. S. J. PENTECOST IN THE CHAIR.

INAUGURAL ADDRESS.

RECENT PROGRESS IN THE TEXTILE INDUSTRIES.

BY S. J. PENTECOST.

I wish to call attention to one or two points of local interest to dyers and bleachers and afterwards to refer briefly to advances that have been made during the last year or two in certain branches of chemical industry connected with lace and hosiery manufacture.

Some years ago I brought before this Society for discussion a question of some interest to the local trades, viz., the development of certain stains in bleached goods, after being either despatched or kept in stock. The particular stains then dealt with were mineral oil stains caused by oil dropping from a shaft or being thrown from a hot bearing. It was shown that this oil penetrated the cuticular layer or envelope of the cotton fibre, and was not removed in the ordinary course of bleaching. Although the goods appeared to be clear and white when finished, the oil from the interior of the fibre oozed to the surface and formed a pale yellow stain. I recall the discussion at this time in order once more to emphasise the need in our local industries for manufacturers to realise the importance of the proper length of time being given for the bleaching process. Manufacturers insist on large quantities of lace goods being bleached within six or seven hours, or in a single night. But Scheurer has pointed out that the oil and waxy matters of the cotton fibre cannot be saponified and removed in less than six hours' boiling where the most suitable alkalis and emulsifiers are used. It is clear, then, that goods having, besides their ordinary impurities, an amount of graphite or mineral oil in parts of their surface, cannot be satisfactorily bleached in the short time given by this hurried process, one which can only be carried out with the aid of dummies to help the penetration. It is further clear that goods hurriedly bleached will not compare favourably with those which have been longer in process, such as Lancashire goods, which are, as a rule, kept by the bleacher for three or four weeks. The purity of the bleach depends very largely upon the thoroughness of the boiling process.

Another stain which has caused trouble by developing after goods have left the bleacher is one which consists of a violet pink coloration, appearing at the edges of goods stocked in the warehouse. For some time this stain was a source of great perplexity both to the chemist and to the bleacher. In some goods brought under my notice, the fault was attributed by a chemist to whom the stain had been submitted, to the formation of a pink manganese salt derived probably from the bleaching powder, in the preparation of which by the Weldon process manganese dioxide is used. It was found, however, that the same thing occurred in goods bleached by powder produced by the electrolytic process, in which no manganese compound is used. It was then submitted to me. Some years previously I had noticed that it had occurred on goods which had been dried in proximity to the ageing chamber used for the aniline black process, and at once the cause of the stain was clear. It was due to the oxidation of the aniline fumes, by which means the faint magenta or mauveine colour was formed on the goods. Recently Böttiger has given further proofs that this stain was a mauveine, that, in fact, it represented pseudo-mauveine, $C_{21}H_{20}N_4$. He obtained this from cotton dyed with aniline black, by extracting it with water acidulated with hydrochloric acid. On evaporation to dryness, the hydrochloride of the pseudo-mauveine remains as a blackish-

⁸ Gazz. chim. ital., 19, 202 (1889).

⁹ Ann. der Chem., 253, 346 (1889). That this decomposition partially takes place when the substance is melted, may be concluded from the form of the melting point curve as observed by Kreman (Sitz. Ber. Akad. Wien, Math. naturw. Kl. 113 Abt. (1), 6, 814; 1904) and by Saposchukow and Rdotlowsky (Journ. russ. phys. Soc., 35, 1073; 1904).

¹¹ Het Gas, Oct., 1905, p. 477.

green mass, readily soluble in alcohol to a red-violet colour. Other reactions on this substance with various reagents left no room for doubt that the violet dyestuff was identical with pseudo-mauveine. Having thus ascertained the chemical nature of this by-product, he set about finding the best method of preventing its formation. Pseudo-mauveine is formed, according to Sir W. Perkin, by the action of various oxidising agents, especially chromic acid, on aniline, and as aniline is always present in small amount in the cotton if oxidation has reached the green stage, it is this aniline which yields pseudo-mauveine on chroming. It should then be possible to prevent this by well washing the greened cotton before chroming. In practice, however, the black turns out thin, uneven, and liable to green, while a small amount of violet is still found. This shows that it is also formed from the oxidation product of aniline which has been fixed on the fibre (*i.e.*, from emeraldine) and chromic acid, but the amount so formed is very small and its formation cannot well be prevented. If, however, as much of the aniline salt as possible is converted into emeraldine in the ageing process, the after-formation of mauveine during chroming will be reduced to a minimum. The conversion can be attained by raising the amount of sodium chlorate in the black padding liquor, taking great care not to increase it too much or the fibre will be tendered. The temperature of the ageing should not exceed 55° C., nor in the chroming process should the strength of the sodium bichromate exceed 10 grms. per litre. Taking precautions such as these, good results are obtained as regards shade, depth, non-greening, etc. It has been thus shown that the red-violet by-product which is formed along with aniline black in dyeing is pseudo-mauveine, and that this is formed chiefly from the unchanged aniline salt present on the greened cotton. By using a large quantity of sodium chlorate and as small an amount as possible of bichromate, the danger of the development of these violet-red stains may be reduced to a minimum.

The processes of bleaching as carried out in the lace and hosiery trades have undergone little alteration during recent years. Most bleachers use caustic soda in place of lime for boiling, generally preferring the higher strengths, *e.g.*, 70 and 77 per cent.; while much of the bleaching powder used locally is now made by electrolysis of salt solution by the Hargeaves-Bird process. *Electric bleaching*—or bleaching by solutions made by electrolysis brine or common salt—has not made much progress in Nottingham. So far as I am aware, only one plant (the Vogelsang) is at present in use. A distinct advance, however, has recently been made in the construction of plant for this method of bleaching, and those patented by Jaeglé, Schoop of Nürnberg, and later Oettel, make the process much more practicable than was the earlier process of Hermite, which was brought before this Section about 18 years ago.

The advantages claimed for modern electrolytic bleaching are:—

(1). The effective bleaching power of the sodium hypochlorite produced, which is claimed to have twice the bleaching power of a solution of bleaching powder containing the same percentage of chlorine.

(2). It is less liable to tender the fabric than ordinary bleach. As it contains no lime or magnesia salts the fibres do not suffer, and the "feel" and appearance of the goods is said to be improved. For this reason also it is an ideal bleach for artificial silk.

(3). Economy over chloride of lime as follows:—(a) Less "sour" or acid is required. (b) Goods lose 2 per cent. less in weight than when chloride of lime is used.

(4). Uniformity in strength of solution: this does not vary as the chloride of lime solution is liable to do.

(5). Cleanliness and convenience are claimed: no lime dust, no smell, and little room required for plant.

In one of the processes mentioned (the Haas-Oettel) a tank of 166 galls. capacity requires 286 lb. of salt to make a brine of 23° Tw. strength. This is circulated in the electrolyser for 12 hours at a temperature of 20° C. The current used is 43 amperes at 110 volts, and this gives a product containing 16.2 lb. of chlorine per 100 galls. or 264 lb. chlorine for the 166 galls., at a cost for power and salt of 3s. 1½d. These latter costs are based on the price of

coal being 10s. per ton and salt 12s. per ton. These figures work out decidedly in favour of the electrolytic method, and it seems probable that where works produce their own current, the electrolytic method is the cheaper; but if the current were taken from our City Corporation, it would come slightly dearer. At some Swiss works where water power is available for generation of current, the cost is brought down considerably. The question of economy therefore lies largely with the cost of the current used. It should be borne in mind, however, that so far as the bleaching of lace is concerned, the cost of the production of bleaching liquor from bleaching powder does not exceed 8 per cent. of the total cost of the bleaching process. The saving claimed therefore by makers of electrolytic plant over the use of bleaching powder is but a very small percentage of the total cost of bleaching.

The electrolytic method of bleaching is in use on the Continent in print and paper works and in laundries; as well as in works in which artificial silk is treated. It may also be advantageous for *wool chlorination*. The application of chlorine to woollen hosiery for the production of an "unshrinkable" finish has come to be extensively practised in this district. It is well known that ordinary bleaching liquor converts woollen fabrics into a gummy mass, but dilute chlorine solution applied carefully has the effect of smoothing down the delicate edges of the scales of the wool fibre, to which the felting properties are attributed. This is probably effected by the formation of small quantities of the gummy substance on the scale edges, and thus it is that the felting and interlocking power of the scale fibre is destroyed.

One method of carrying out this process is as follows:—A solution of hypochlorite of soda is prepared by dissolving 28 parts by weight of bleaching powder in 10 gallons of water, allowing to settle and decanting the clear liquor. To this is then gradually added with constant stirring 16 parts of pure alkali (Na_2CO_3) dissolved in 14 gallons of water. The liquor thickens up and then slowly becomes thin after the whole of the alkali has been added. The precipitate is allowed to settle and the solution decanted. The soda should be in excess of that required theoretically, as it prevents to some extent the yellowing of the wool. For the same reason it is advisable not to work with a bleaching powder solution of too great a strength of available chlorine, otherwise chlorate is likely to be formed, and this has a yellowing action on the wool. One gallon of this liquor is used for every 10 lb. of wool. It is well to add this in two lots instead of all at once. Five minutes' treatment of the wool may be given in the first bath, sufficient hydrochloric acid being run in gradually to set free the chlorine. The liquor is then run off and a second similar bath given. The goods are afterwards rinsed, and then in order to restore the colour, treated in a bath of bisulphite of soda in the proportion of 1 pint of bisulphite to every 20 lb. of wool with the gradual addition of dilute sulphuric acid. The acid must be added very slowly. The goods are then rinsed, scoured with soap, and rinsed off.

It is doubtful whether woollen hosiery treated in this manner maintains the warmth associated with the wearing of woollen hosiery, and it is certain that it wears into holes more quickly. This is probably due, not to a tendering of the wool fibre, but to the fact that those portions of the garment exposed to the greatest wear do not felt up in washing and thus the increased strength which felting gives is not obtained.

According to Pearson (Soc. Dye and Col. Journal, 1909), wool treated by this process may be distinguished from non-chlorinated wool by two simple tests, *viz.*:—

(1.) If a drop of water be placed on a piece of treated fabric it is at once absorbed and the wetted part has a round contour, while in the case of ordinary wool, the drop is absorbed slowly and the contour of the wet part is irregular.

(2.) On wetting out chlorinated wool and rubbing together two surfaces of it between finger and thumb, a characteristic scroop or crispness of touch is felt.

Lime soap in silk washing.—In the lectures on bleaching given before this Section last session the importance of softened water was strongly insisted upon, and it was shown how the sticky lime soap arrested the pedesis, *i.e.*, the move-

ment of dirt particles in solutions, phenomena formerly known as the "Brownian movement." Important as pure water is in cotton bleaching, it is doubly so in the case of silk where hard water not only means loss of soap, but inferior colours and loss of lustre, with bad penetration of stiffening agents. And here I wish to point out a difficulty which often troubles the silk lace dyer. In preparing silk for the lace machine, it has to be softened in order that it may be wound compactly upon the beams and bobbins. These latter consist of two thin brass discs fixed close together on a central perforated axle. The silk is soaked in a 10 per cent. soap solution at 120° F. for 8 to 12 hours. It is then wrung and hung up in a room to dry at about 85° F., afterwards being wound on the bobbins by an ingenious machine which winds perhaps 80 together. These bobbins hold about 120 yards of silk. The filled brass bobbins are threaded on to a spindle, pressed tightly together by an arrangement of screws and nuts, and put into an oven heated by a steam jacket. Here they are subjected to a temperature of 150 to 200° F. Care is taken that the temperature is not raised too high, lest the silk gum should melt and fasten the threads together. If water or steam be introduced the same fault may occur and the silk be spoilt.

This process used to be and is now to some extent carried out by special silk washers, who were sorely tempted to weight the silk with soap, fats, etc., and to abstract a percentage of the silk entrusted to their care for their own profit. This practice, we believe, does not obtain now, and the fact that magnesium chloride, Epsom salts, common salt, soap, fats, and more rarely glue, are used occasionally to weight raw silk probably led up to it. The need, however, is thus emphasised for careful valuation of silks in the conditioning house, on the basis of obtaining the net weight of *boiled off* silk sold. But the point I wish to call attention to is that the soaps used for this soaking are principally palm oil and tallow soaps. These with the hard water of this neighbourhood form lime soaps which become fixed in the silk gum and cannot be entirely removed, unless the silk is boiled off. They therefore interfere with the lustre and springiness of the lace fabric when finished, and the tulles, veilings, and laces which contain lime soap compare unfavourably with those finished in continental towns, where a good supply of soft water is available. It is therefore highly desirable that lace makers should wash their silk in softened water, or if this is not to be had, that they should at least use soaps which are least affected by hard water, viz.:—palm kernel oil soaps or a sulfonated oil soap.

Silk weighting.—I come now to the consideration of silk weighting as carried out by the dyer. The practice of weighting silk has hitherto, perhaps fortunately, only interested silk lace dyers to a limited extent.

The principal goods weighted here are silk bobbin, nets, tulles, and some few glove fabrics. The late Sir Thomas Wardle, in a lecture given some years ago before this Section on Tussah silk, condemned the continental practice of heavily weighting silk, and many authorities have echoed this condemnation since.

In spite of this, however, the demand for weighted silks has increased rather than diminished, owing to the fact that a weighted silk is naturally cheaper than a pure silk. When heavily weighted by the tin phosphate or silico-tin-phosphate processes, defects in the nature of stains and tender or rotten places are liable to develop after storage and keeping in stock.

During recent years these defects have caused continual trouble, and the matter has been considered by the Crefeld Chamber of Commerce as well as by the Silk Associations of Zürich and Turin. Proposals were made that dyers should guarantee the weighted silk for 1, 1½, or 2 years, while others suggested standardising the method and degree of weighting. Ultimately, however, investigations were made by Gnehm and Baenziger, Gianoli, and Sisley, which showed that the elasticity of the silk decreased in proportion to the weighting absorbed by the silk. Numerous experiments also showed that a temperature of 100° F. in six months weakened the weighted silk considerably; while the action of light was very pronounced—a fabric weighted 130 per cent. being tendered in eight days by exposure to sunlight. Sisley considers

that the light acts by reducing the stannic hydroxide, thus setting free the oxygen which alters the fibre. With a view to finding a remedy for this, in 1903 several investigators suggested and patented the use of certain alkaline sulpho-cyanates, which served to paralyse the action of oxygen and the chlorides, and to increase the resistance of weighted silks to the action of light. Later, Sisley patented the use of thio-carbamide for this purpose, and this is shown by a number of trials extending over three years to have given satisfactory results. It has now been adopted by several large firms of silk dyers on the Continent.

Hydroquinone and tannin have also been suggested for the same purpose. In the case of sulphocyanic acid or its salts the addition is made to the tin bath, whereas when hydroquinone, hydroquinonesulphonic acid, or thio-urea are used they are applied as an after treatment to the silk goods.

Aniline Black.—The dye-stuff known as Aniline Black holds a place in cotton-dyeing second in importance to no other colouring matter, yet it is surprising how little definite information we possess as to its chemical constitution. Excepting the valuable investigations of Caro and of Wiltstätter and Moore, little has been published in recent years. During the present year, however, Prof. Green, of Leeds, in a paper read before the Society of Dyers and Colourists (this J., 1909, 700), has not only adduced plausible explanations of the chemical reactions taking place in the three successive stages of the production of (1) Emeraldine, (2) Nigraniline, (3) Ungreenable Black, but has indicated and introduced a new commercial method for the production of aniline black by air oxidation.

It has long been found that in the production of an "aged" or "oxidation" black upon cotton materials, in spite of the greatest precautions in the ageing chamber with regard to humidity, temperature, and ventilation, a certain diminution of strength of the material is unavoidable. This "tendering" is the cause of considerable loss. Its origin is twofold:—(1) The hydrolytic action of hydrochloric acid or other mineral acid set free from its combination with aniline; (2) The oxidising action exerted by the chlorine or oxides of chlorine produced from the chlorate, which tend to convert the cotton into oxycellulose.

According to Prof. Green, following Beltzer, the second of these two causes is by far the more important, though the liability to oxidation of the cellulose increases with its acidity. Various attempts have been made in the past to reduce the acidity of the aniline mixture and thus lessen the tendency to production of oxycellulose. They have been attended with but little success, as the acidity of the mixture cannot be materially reduced without at the same time greatly retarding the development of the necessary emeraldine.

Prof. Green has, however, in a process recently patented endeavoured to overcome this defect by replacing the chlorate oxidation by the much milder action of atmospheric oxygen. His method is based upon the fact that the presence of small quantities of paradiamines or of para-amido-phenols increases the oxidisability of aniline by oxygen. (Eng. Pat. No. 16,189 of 1907, see also this J., 1908, 683.)

It is remarkable how small a quantity of a para-diamine exerts a catalytic effect. Even 2 per cent. of *p*-phenylenediamine on the weight of aniline employed produces a marked result, though larger quantities than this are usually employed in practice. Other para-diamines may be used also.

The new process is already being successfully used for piece dyeing, and bids fair to extend to the dyeing of cotton yarn, cotton hosiery, and raw cotton. The cloth is padded with a solution containing aniline, hydrochloric or other acid, a copper salt, and a small quantity of paraphenylenediamine. It is then dried and afterwards oxidised by exposure to air with or without a passage through an ageing chamber. The emeraldine having been thus developed on the material, is converted into black by chroming. The black produced is said to be fully equal in brilliancy and depth of shade to an ordinary black dyed by the copper chlorate process. In addition to the great advantage of leaving the material stronger, the process presents, according to Prof. Green, a technical

superiority over the older processes in the following respects:—

(1) Greater cheapness of production owing to a more complete utilisation of the aniline; (2) Greater stability of the padding solutions, on account of the absence of chlorate; (3) No evolution of poisonous vapours in the ager.

If this new method does, as is claimed for it, produce a brilliant aniline black upon goods without tendering, and has indeed the other advantages named, it is well worthy of the careful consideration of those members of our Society more specially interested; but in any case, as a recent example of chemical research producing valuable results in technology, it demands the attention and approbation of us all.

New vat dyes.—Perhaps the most notable advance in dyeing cotton goods during the past year has been the introduction of a series of vat dyes giving a wide range of bright colours which are very fast to light, washing, and bleaching. They are not, however, fast to the soda boil.

The first of this series was the thio-indigo red of Friedländer, which was manufactured by Kalle and Co. A large number of patents have since been taken out by various colour firms for blues, violets, scarlets, and other colours dyed by the vat method. This method has been made possible and easy of application by the discovery of the stable hydrosulphites. These are compounds of sodium hydrosulphites and formaldehyde, and they are sold under the names of Hyraldite A., Hydrosulphite N.F., Rongalite, etc. Decroline, another of these substances, is the zinc salt of formaldehyde and sulphonylic acid. It is insoluble in water, but soluble in acids, and is used as a stripping agent by the garment dyer, as well as for bleaching straw.

Artificial silk.—The rapid progress made during the past year in the manufacture of artificial silk has brought this fibre into extensive use for the weaving of various fabrics, and its production has already become an important chemical industry. In lace manufacture its use has rapidly grown, more especially for embroidered laces. On Lever's machines it is more difficult to work, owing to the chafing through the intricate parts of the machine; but the trouble is being gradually overcome. The total output is estimated at 5000 tons per year, and of this England produces over 700 tons. Works at Coventry are turning out large quantities of material, and new works are being erected at Flint for the Vereinigte Glanzstoff Fabriken. Other works are also projected.

The "A" silks are prepared by dissolving cellulose or its derivatives in various solvents and forcing the fluid through capillary tubes or fine orifices into a coagulating solution, from which the prepared cellulose issues in the form of a fibre, which is then reeled off with other fibres similarly produced.

Two classes of "A" silk may be distinguished, viz.: That prepared from nitrated cellulose in ether-alcohol solution and that made from aqueous cellulose solutions. The first of these comprises the Chardonnnet and Lehner and Besançon silks, and in the second class are those silks prepared from cuprammonium solutions of cellulose and from viscose. The zinc chloride-cellulose solution forced through an orifice and coagulated by alcohol or acetone, also produces a thread of similar characteristics (Dreaper and Tompkins).

Chardonnnet silk is made by projecting collodion through fine glass tubes into air or water, where solidification occurs. The resulting fibre is then wound on a reel and the ether, etc., recovered. The silk thus produced is denitrated by treating with ammonium sulphide. This product is extraordinarily brilliant, but owing to its loss of strength and elasticity when wet, is unsuited for manufacturing goods that have to be stretched or pulled out.

For this reason and the important factor of relative cost, this class of artificial silk is being gradually replaced by those products obtained by dissolving the cellulose direct, without previous nitration.

The Glanzstoff and Thiele processes consist in dissolving cellulose in ammoniacal solution of copper hydroxide and forcing the liquid through fine spinning nozzles into a precipitating medium consisting of 32 parts caustic soda,

8 parts glucose, and 100 parts water. In this, the copper is dissolved out of the fibre at a temperature of 50° C. for fine threads and 75° for thick threads, gradually reduced to cuprous oxide and precipitated, giving a reddish colour to the bath. This by contrast with the bluish shade of the thread, helps the worker to detect broken threads. The threads are afterwards washed in dilute acid in order to dissolve out copper compounds and caustic soda. In Dr. Thiele's process very fine threads are produced. The sample shown is a silk of 45 deniers, the usual thickness of this class of silk being 120 deniers or more.

Viscose silk is produced from viscose, which is made by treating cellulose with caustic soda (mercerising), and subjecting the product to the action of carbon bisulphide vapour. The cellulose xanthate thus formed is dissolved to 8 to 10 per cent. cellulose strength and projected into suitable aqueous precipitating media.

This class of silk is being produced in increasing quantities at the works in Coventry, and by reason of its softness, brilliance, and strength when in a wet state is finding its way into the Nottingham and Lancashire textile industries. It is supplied in sizes of 120 deniers and upwards. In the micro-photograph it will be seen that the Thiele silk of 45 deniers is as fine as the natural silk. I may remark in passing that large profits have been earned by some of the companies engaged in these processes—a Belgian company, for example, reported last year 145 per cent. profit, while a German company also paid 40 per cent.

Besides the silks mentioned, Messrs. Bayer and Co. have patented the production of threads made from cellulose acetates dissolved in chloroform and precipitated by ethyl alcohol, benzene, or by other reagents.

Filaments from gelatine and casein have also been made, but have not proved successful commercially.

Time does not permit me to do more than call attention to the so-called soluble starches—especially to a product recently put on the market under the name of Feculose, which is made by the action of glacial acetic acid on highly dried starch—the acetic acid being afterwards recovered by distillation. By the kindness of Mr. J. Allan, Managing Director of Messrs. Wotherspoon, Limited, I am enabled to show you some films given by it, which show great transparency, suppleness, and brilliancy. The specimens of paper also show its applicability in paper coating, and in the manufacture of fruit pastilles. (See this J., 1909, 288.)

PROF. W. M. GARDNER IN THE CHAIR.

THE COST OF TREATING TRADE EFFLUENTS.

BY W. McD. MACKEY AND J. MILLER.

The treatment of trade effluents in such wise as to satisfy the authorities who have charge of the rivers and streams is a subject that is now engaging the attention of chemists. It was thought, therefore, that a short paper on the subject of cost of the chemicals used, might be of some interest. No rule can be laid down as to what will satisfy an authority in charge of a stream; obviously, the effluent into a trout stream must be purer than that which may pass into a stream in a manufacturing district, where the avoidance of active nuisance is all that can be aimed at. The requirements of the authorities in a manufacturing area may be regarded as met if the effluent is free from matter in suspension; is neutral in reaction or slightly alkaline; contains nothing of an actively poisonous or offensive nature; and is not heavily charged with organic matter. Freedom from matter in suspension falls more to the engineer than the chemist—though the type of chemical treatment is not without influence on the subsequent clarification. In any case the chemist is asked to treat effluents so that when clarified they will at least fulfil the other conditions mentioned.

Waste dye effluents naturally bulk largely in this district, and the chemical treatment usually resolves itself into addition—in the right proportion—of lime alone, or of a salt of aluminium (usually aluminoferric) with lime, or soda, or both. If lime alone be sufficient, the cost is very low. The following table gives the cost per pound of the principal precipitants and also of neutralising effect compared with lime:—

	Price in pence, per lb.	Price per ton.
Lime	0.085	£ 8. 16. 0
Aluminoferric	0.29	2 15 0
Copperas	0.29	2 15 0
Soda ash	0.59	5 10 0
Sodium hydroxide	1.15	10 15 0
Barium hydroxide	1.07	10 0 0
Barium carbonate	0.59	5 10 0

Cost of neutralising effect compared with lime.

Lb.		Pence.
1.00	Lime (CaO)	0.085
1.89	Soda ash (Na ₂ CO ₃) equals 1 lb. lime ..	1.11
1.43	Sodium hydroxide (NaHO) ..	1.64
5.62	Barium .. (BaH ₂ O ₂ .8H ₂ O) ..	6.01
3.51	.. carbonate (BaCO ₃) ..	2.07

Thus, 3 lb. lime per 1000 gallons (a usual quantity) only costs 0.25 penny, but if 1 lb. aluminoferric or copperas be also added, the cost is rather more than doubled, and it is to be remembered also that the addition of lime itself must be increased owing to its reaction with the aluminium sulphate. Soda ash is seldom employed except where the treated effluent is used again in the mill, either for dyeing or boiler purposes. Generally soda ash when used as a neutralising and precipitating agent, gives with dye liquors a worse colour than when lime is used.

In some cases where the precipitate with lime is very light, the addition of an aluminium salt is useful as giving a denser precipitate, and the subsequent clarification of the effluent, when a subsidence method is employed, is facilitated. But beyond this advantage we have not found, in the dye liquors with which we have had experience, that the addition of an aluminium salt gives any advantage, either as shown in the colour of the final effluent, or in purification as indicated by the "Oxygen absorbed" determination. Nor when an aluminium salt is used does it seem to matter whether it is added before or after the lime. In a paper by one of us, read last year at Bradford before the Society of Dyers and Colourists (Feb., 1909, No. 2, Vol. xxv.), a table is given showing the results of some experiments from which we may quote as follows:—

	Oxygen absorbed imparts per 100,000
No. 1.	
Untreated effluent (filtered through filter paper)	17.0
After treatment with lime	4.68
" " " aluminoferric then lime ..	4.40
" " " lime then aluminoferric ..	4.70
No. 2.	
Untreated effluent (filtered through filter paper)	16.8
After treatment with lime	4.80
" " " aluminoferric then lime ..	4.80
" " " lime then aluminoferric ..	4.72
No. 3.	
Untreated effluent (filtered through filter paper)	7.24
After treatment with lime	4.24
" " " aluminoferric then lime ..	2.44
" " " lime then aluminoferric ..	3.28
" " " aluminoferric only	4.36

The last might be taken as favouring the addition of aluminoferric before the lime, and certainly this was our decided opinion before the experiments were made.

Either with or without the addition of aluminoferric or alumina in some form, the use of lime is attended with the disadvantage that the treated effluent—no matter how pure from organic contamination—is still very hard. This is owing to the large amount of acidity shown by most of the waste dye liquors, against which lime has to be added. Whether the turning of what may be described as very hard water into a stream can be considered a nuisance, either in the ordinary or legal sense, must depend on the nature of the particular stream. If every mill on a stream were turning in excessively hard effluent, it would be a hardship on those who had a prescriptive right to use the water for steam raising purposes.

The practice of "stripping," which involves the use of acid, has been increasing of late years, and to this is due the excessive acidity which is occasionally met with in untreated effluents, resulting in excessive hardness in the treated effluents. If the question of hardness in the effluents turned into the stream ever became of importance, the difficulty could be met by reserving the stripping liquor for special treatment.

The use of barium hydroxide has been suggested, and as the acid in waste dye liquor is for the most part sulphuric, the suggestion seems a good one from the chemical point of view, but here cost is prohibitive, at least at the present price; a reference to the table showing that against lime at 0.085 penny per pound, barium hydroxide is 1.07 penny, and its neutralising effect compared with 1 lb. of lime is as 5.62 to 1. The cost of 5.62 lb. of barium hydroxide being 6.01 pence the comparative cost of neutralising effect is as 70 to 1. Even barium carbonate which is 0.59 penny per lb., when compared with lime is as 3.51 to 1, and the relative cost is as 24 to 1. It is to be remembered also in connection with barium hydroxide that the acidity to be neutralised is not entirely due to sulphuric acid.

The question of colour in effluents has not so far become acute, that is to say, so long as the conditions named at the beginning of the paper are fulfilled, the authorities give a very wide margin in the matter of colour. But no doubt if reasonably cheap methods of decolorising waste dye liquors were available, the authorities would press manufacturers to apply them, but no general method of treatment can be successful with such complex liquids.

There is another class of trade effluent, the treatment of which at present is very unsatisfactory, i.e., spent gas or ammonia liquor. These liquors are heavily charged with free lime and contain phenols, sulphocyanides and possibly cyanides; and though the recovery of valuable by-products always seems imminent and possibly is done on a small scale, yet we do not know of any method which could be compared with, say, the well-known process of the recovery of seak oil from seak or soap sud. We merely aimed at the total destruction of the oxidisable matter, and our results were as follows, being laboratory experiments only:—

Ozone in alkaline effluent: The sulphocyanides and phenols were destroyed, and the "oxygen absorbed" reduced from 302.9 to 13.9 parts per 100,000, the cost being about 15s. per 1000 gallons. This was done in 1907 and no doubt ozone could be made cheaper now.

Oxygen: The effect of oxygen at 15 atmospheres pressure was tried on samples of effluent: alkaline with soda, with lime, and acid with sulphuric acid respectively. No destruction of sulphocyanide or phenol, nor reduction of "oxygen absorbed" was obtained.

Permanganate and sulphuric acid: The sulphocyanides were destroyed; "oxygen absorbed" in resulting effluent was not determined. The amount of permanganate required per 1000 gallons was about 50 pounds. The effect of hydrogen peroxide and of electrolysis (using iron electrodes) was tried on the alkaline effluent, without result. One point in favour of the use of such reagents as ozone, oxygen, and hydrogen peroxide is that they only add oxygen to the effluent.

Evaporation is successfully employed when waste heat or gas is available, as at Scotch blast furnaces. If heat be considered a chemical and the price be stated in terms of coal, in direct evaporation 9 tons

of water is evaporated by 1 ton of coal, and coal at a low pit price of 4s. per ton works out at 2s. per 1000 gallons. By multiple effect evaporation much higher efficiency can be obtained but this means expensive and complicated plant, and even taking the efficiency as doubled, the cost is still 1s. per 1000 gallons. In the case of waste ammonia liquor, evaporation would readily lend

itself to the recovery of residuals, but we know of no case in which this has been effected. So far as by-product coke ovens are concerned, there seems good reason to hope that, owing to the more scientific methods that are now coming into practice in the recovery of tar and ammonia at modern plants, the waste liquor in its present offensive form will soon be a thing of the past.

Journal and Patent Literature.

PATENT SPECIFICATIONS may be obtained by post by remitting as follows:—

English.—8d. each, to the Comptroller of the Patent Office, W. Temple Franks, Esq., Southampton Buildings, Chancery Lane, London, W.C.

United States.—1s. each, to the Secretary of the Society.

French.—1 fr. 25 c. each, to Belin et Cie., 56, Rue des Francs Bourgeois, Paris (3e.).

German.—1 mark each (with full particulars) to Kaiserlich Patentamt, Berlin, Germany.

I.—PLANT, APPARATUS, AND MACHINERY.

PATENTS.

Liquefied gases; Storage vessels for —. L. A. Groth, London. Eng. Pat. 13,588, Dec. 16, 1908.

VALVES of porous material, such as cardboard, are provided in vessels for storing liquefied gases, in order to relieve pressure. A jacketed vessel is provided in its upper part with such a valve opening into the jacket, and in its lower part with a similar valve opening into the atmosphere.—J. W. H.

Separation of solid material from liquids; Apparatus for —. The Wilfley Mining Machinery Co., Ltd., and F. L. Roubush, London. Eng. Pat. 23,189, Oct. 30, 1908.

A HORIZONTAL perforated drum covered with filtering material is rotated while partially immersed in a tank containing the material to be filtered. A partial vacuum is produced inside the drum and the filtrate removed by means of a pipe passing through the hollow axle of the drum. The material is fed into the tank up to a constant level by means of a valve controlled by a float and is kept in agitation by a stirrer rocked by an eccentric upon the drum axle. As the separated solid matter is carried round upon the filtering material, it is squeezed by an apron supported across the drum and washed with water at the same time. The washed material is it reaches the level of the material in the tank again, is removed by a scraper from the apparatus and the cleaned filtering material at once re-commences filtration of the material in the tank.—J. W. H.

Filter [for air]. A. Rahe, Assignor to K. and T. Möller, Ges.m.b.H., Brackwede, Germany. U.S. Pat. 930,561, Aug. 10, 1909.

A NUMBER of rectangular frames open at one side are arranged in a series with their open sides alternately facing in opposite directions. A length of filter-cloth is folded over the frames so as to form a series of pockets facing alternately in opposite directions. The frames are then clamped together and fitted into a casing. The air enters one side of the casing, enters the openings on one side, passes through the single layer of fabric between adjacent pockets, and is discharged through the openings on the other side.—W. H. C.

Filter of progressively decreasing porosity. C. Chau. Second Addition, dated Jan. 20, 1909, to Fr. Pat. 372,281, Dec. 5, 1906 (this J., 1907, 599; 1908, 493).

THE liquid is supplied to the filter from an overhead reservoir arranged on the principle of the "Mariotte bottle" in order to obtain a constant and steady feed. The air-supply pipe to this reservoir is bent and prolonged downwards until it dips into the lower reservoir, into which the filtered liquid flows. When sufficient liquid has accumulated in this lower reservoir to seal the end of the air pipe, the supply of air to the Mariotte apparatus is cut off, and filtration ceases automatically until some

of the filtered liquid is drawn off. Then, as soon as the lower end of the air pipe becomes unsealed, air passes up into the upper reservoir and filtration automatically commences again.—W. H. C.

Filter-presses. J. B. Vernay. Fr. Pat. 402,250, April 20, 1909.

THE plates of the press are provided with vertical ribs forming channels on the upper part of each face and with broken horizontal ribs forming zig-zag channels on the lower part. The washing liquid is supplied separately to the upper end of each of the vertical channels to ensure thorough washing of the cake.—W. H. C.

Evaporator. T. Suzuki, Sunamura, Japan. U.S. Pat. 937,114, Oct. 19, 1909.

THE apparatus consists of a chamber divided by vertical, perforated partitions into ingress, egress, and central compartments. The liquid to be evaporated is contained in shallow pans supported in rows one above the other in the central compartment, space being left between each row of pans for the passage of air. A relatively low pressure is maintained in the egress compartment and a regulated quantity of air is supplied to the ingress compartment, so that a steady flow of air, equally distributed through all the perforations, is maintained across the central compartment.—W. H. C.

Dryer. R. K. Meade, Nazareth, Pa., Assignor to J. W. Fuller, jun., Catasauqua, Pa. U.S. Pat. 937,255, Oct. 19, 1909.

THE materials to be dried are fed through the shoot, 15, into the chamber, 12, from which they pass through the tubes, 10, and are discharged from the other end into the chamber, 9. The tubes, 10, pass through and are rotated with the drum, 8. The gases from the furnace, 6, pass through the drum exteriorly to the tubes, 10, and return through the tubes, 10, to the stack, 15. —W. H. C.

Dehydrating apparatus. D. Porter. Fr. Pat. 402,151, April 17, 1909.

THE articles to be dried are placed on moulds or supports carried on endless bands passing through a chamber through which a current of hot air is caused to flow in an opposite direction. The supports are automatically transferred from one band to the next at each end of the chamber.—W. H. C.

Rendering bodies transparent or translucent. H. Streller. Fr. Pat. 401,961, April 10, 1909. Under Int. Conv., April 11, 1908.

The body to be rendered transparent is impregnated with a solution which has approximately the same index of refraction as the substance treated. If the body contains water or other fluid this is first extracted.

—W. H. C.

Heating solid, fluid, and gaseous materials by means of the reaction heat developed on the formation of metallic sulphides. A. Lang, Karlsruhe, Germany. Eng. Pat. 22,118, Oct. 19, 1908. Under Int. Conv., Oct. 21, 1907.

SEE Fr. Pat. 395,536 of 1908; this J., 1909, 591. —T. F. B.

II.—FUEL, GAS, AND LIGHT.

Coal dust; Experiments with — in the testing gallery of the Rossiter coal district, Austria. Czaplinski and Jicinsky. See XXII.

Coal; Determining the volatile matter of —. H. Beck. J. Gasbel., 1909, 52, 960–962. (See also Constant, this J., 1909, 692.)

IN view of the irregular results furnished by the Muck method with different quantities of substance and kinds of crucible, it is recommended that 1–5 grms. of the finely-powdered coal be placed in a platinum or porcelain crucible, tightly covered with a perforated lid, and strongly heated for a few seconds to start the evolution of gas. As soon as the gas ignites, the flame is lowered and the rate of heating regulated so that the gases will ignite on the approach of a small flame, without, however, continuing to burn after the latter has been withdrawn. When ignition is no longer produced by the test flame, the temperature is again raised for about a minute. The end point of the test is reached when the yellowish hydrogen flame from the crucible goes out; any incrustation on the top of the lid being then burned off. The under side of the cover and the sides of the crucible should remain coated with deposited carbon. The results are very concordant, whichever kind of crucible is used, and are 2–4 per cent. higher than those from the Muck method. With regard to the relation between the yield of coke in crucible tests and in the coke-oven, the author considers that no comparison is practicable, but that the value of the crucible test is chiefly confined to the "degree of volatility" of coal in the crucible, this degree expressing the amount of volatile matters in 100 parts of the pure

coal, after deducting the content of moisture and ash. These results should enable a comparison to be drawn as to the relative susceptibility of the different kinds of coal to chemical decomposition, the factor of volatility providing a constant for each coal and serving to estimate its technical value. —C. S.

Gas oils; Valuation of —. L. Kalbfuss. J. Gasbelucht., 1909, 52, 933–936.

THE author has carried out tests with four cheap Austria oils and one German oil in the carburetted water-gas plant of the Darmstadt gas-works, which comprises two separate systems each with a capacity of about 12,500 cb. m. of gas per 24 hours. The results are shown in the following table:—

Gas testing. "Local Govt. Officer," Oct. 30, 1909. [T.R.]

AMONG the Acts passed during the current Session of Parliament, affecting the work of the London County Council, is the Gas Light and Coke Company's Act, 1909, which received the Royal Assent on August 16th, 1909. The Act makes certain alterations as regards the standard quality of the gas to be supplied by the company in London.

As from the date of the passing of the Act, the standard illuminating power of the gas was reduced from 16 to 14 candles, thus placing the company in a uniform position in this respect with the other two metropolitan gas companies. Provision is made for a consequential reduction in the standard price, etc., of gas, and for the company to supply, *gratis*, burners suitable for the lower illuminating power in place of those already in use. The standard of calorific power fixed is 125 calories net per cubic foot of gas, with an allowance of 12½ calories (10 per cent.) on an average of each of three days, or of 18½ calories on any one day; that is to say, the company is now liable to forfeitures if the calorific power falls below 106½ calories on any one day or below 112½ calories on an average of three days. The Board of Trade is authorised to vary the standard on the expiration of three years on appeal by either the company or the Council.

The Public Control Committee of the County Council have arranged for the testings for calorific power, which up to the passing of the Act were taken for information only, to be continued, but for only one testing for illuminating power with the flat flame burner to be made weekly on Sundays at each testing place, instead of three testings daily, the daily testings for sulphur impurities being continued; and that a test for calorific value on Sundays shall be substituted for the usual illuminating power testings by means of the argand burner. In view of the diminishing importance of illuminating power testings, and the general unification of the standard, the Committee have given authority for the number of testing places at which such testings shall be made on Sundays in the districts of the two companies not working to a calorific standard, to be varied from time to time.

Smoke tintometer. Lowdon. See XXIII. Apparatus.

PATENTS.

Fuel; Artificial —. H. C. Morris, Swansea. Eng. Pat. 6163, Mar. 15, 1909.

POWDERED coal is mixed with powdered maize or other grain, or with flour derived therefrom, in the dry con-

dition, together with finely-ground pitch. The dry mixture is passed into a pug-mill and steam is introduced. The mass is finally moulded into briquettes. Suitable proportions of the binding materials are 1 part by measure of maize, etc., and 5 parts of pitch, to 94 parts of coal.

—A. T. L.

Briquettes; Agglomerating powdered coal of all kinds for the formation of — without the use of resin or other binding agent which would cause smoke, &c., during combustion. E. M. Heckel. Fr. Pat. 402,247, April 20, 1909.

THE process consists in the use as binding agent of a material prepared in the following manner:—0.65 grm. of potassium bichromate is dissolved in 100 c.c. of warm water, and 25 grms. of rice flour are added. The mixture is heated to 90°–100° C. and stirred into a paste. The paste is kept at 50°–60° C. and stirred, while 10 grms. of Portland or other cement are added. Finally, 1 kilo. of the powdered fuel to be agglomerated is mixed with the binding agent, the mass is formed into briquettes and dried. The proportions used vary with the fuel, those given being suitable for anthracite or steam-coal.

—A. T. L.

Fuel; Plant for the treatment of — and the recovery and primary separation of the by-products from same. W. G. Moore, Birmingham, and W. A. E. Crombie, London. Eng. Pat. 6966, Sept. 30, 1908.

THE plant comprises a battery of inclined retorts in which a high vacuum, for example a vacuum of 25 inches, is maintained, as in Eng. Pat. 7732 of 1906 (this J., 1907, 461), and a condenser or series of condensers arranged between the retorts and the vacuum pump. The gases from the retorts pass successively through air-cooled and water-cooled condensers, before reaching the vacuum pump, whereby the by-products are fractionally separated. From the vacuum pump, the uncondensed gases are discharged into a receiver provided with a catch-pot and further cooled to condense as much as possible of the by-products. If desired, these gases may be forced by a compressor through a coil and finally be allowed to escape against a series of inclined perforated plates whereby a further quantity of by-products (benzene) is condensed. The retorts are of metal and are completely encased in a perforated refractory jacket built up of sections and held in place between rebated blocks surrounding the retorts at intervals along their length.—A. T. L.

Gas retorts. R. Dempster and Sons, Ltd., and R. M. Brooke, Elland, Yorks. Eng. Pat. 1937, Jan. 27, 1909.

THE invention relates to the heating of vertical gas retorts arranged in a setting divided into compartments by horizontal partitions as described in Eng. Pat. 16,405 of 1908 (this J., 1909, 647). In order to ensure uniformity in the heating, each horizontal compartment is divided by vertical walls into a number of parallel flues in such a manner that only half of each retort in each row of retorts is heated by the gases in one flue. One or more vertical combustion chambers are provided adjacent to the retort setting, and orifices are provided so that each of the horizontal flues receives a separate stream of gases from the combustion chamber. These separate flues unite at the side of the setting remote from the combustion chambers, and the whole of the gases from one combustion chamber passes in the reverse direction through a horizontal flue adjacent to the end wall of the setting so as to heat the outer surfaces of the retorts in the end row, and then to the regenerators.—A. T. L.

Gas generators. G. Schimming, Berlin. Eng. Pat. 21,660, Oct. 13, 1908. Under Int. Conv., Oct. 14, 1907.

THE patent relates to gas-generators working with a down-draught in order to produce gas free from tar, from bituminous fuel. The raw fuel is fed mechanically in small quantities to the top of the fuel column, and in order to accelerate the transmission of heat to the raw fuel, the air supply is made intermittent, being interrupted for example 120 times per minute by a mechanically operated valve on the air pipe. The gas generated while

the air supply is cut off, penetrates into the layer of fresh fuel. In order further to promote this heating of the fresh fuel, a pump may be provided, open either to the air chamber above the fuel or to the gas chamber below the fuel column, and operated synchronously with the valve so as to draw or force the gas up into the layer of raw fuel while the air supply is interrupted.—A. T. L.

Gas-producer for the destruction of refuse and the gasification of fuels and their waste-products. V. Sepulchre. Fr. Pat. 401,859, Aug. 11, 1908.

THE gas producer comprises a lower, or gas-producing chamber without a grate and with tuyères in the vertical walls, and an upper chamber in which the refuse, &c., is heated by the gas from the lower chamber. This upper chamber contains a long vertical cylindrical shell arranged centrally within it, into which the refuse is charged, the hot gases from the lower chamber circulating around this shell before reaching the gas outlet. The moisture and gases liberated from the refuse, &c., in the upper chamber may be led away by a pipe which terminates in a series of truncated conical hoods within the mass of refuse, or this pipe may lead down into the gas-producing chamber when it is desired to destroy the tar.—A. T. L.

Gas producers. Morgan Construction Co. Fr. Pat. 402,413, April 26, 1909.

THE lower part of the gas-producer chamber is of inverted truncated conical form, and is supported upon a rotating water-trough so as to rotate with it. A stationary casing fixed to the upper part of the producer extends downwards outside the rotating part of the producer and is sealed by the water in the trough. The vertical space between the upper edge of the rotating part and the lower edge of the fixed part of the producer is filled by a horizontal annular plate, supported by hooks from the fixed outer casing, in order to prevent the passage of fuel or ash. The water-trough is supported on wedges on a rotating ring, and its position is adjusted vertically by means of these wedges, leaving sufficient play between the fixed and rotating parts of the producer to allow for expansion. The outer wall of the water-trough is outwardly inclined, and the ash is removed automatically as the trough rotates, by a stationary scraper in the water-trough arranged adjacent to its outer wall, and suitably inclined, so as to lift the ashes over the top edge of the trough. To control the rate at which the ashes are removed, this scraper may be adjusted parallel to itself and toward or away from the bottom of the trough, and an opening through which the ashes are discharged may be regulated by a sliding cover.—A. T. L.

Gas-producer. E. Gobbe. Fr. Pat. 402,767, May 6, 1909. Under Int. Conv., May 16, 1908.

A GAS-PRODUCER for the manufacture of lighting gas and coke comprises a tall vertical cylindrical chamber with hollow walls of refractory material. The interior of this chamber communicates with the interior of the hollow walls by orifices at about the centre of its height. The producer is heated initially by burning fuel in the lower part, the products of combustion escaping through the hollow walls to a chimney. The upper part of the producer is then charged with coal and the gases distilled from the coal are drawn off by a fan. A part of these gases passes downwards and is admitted to the lower end of the producer so as to carry heat from the coke therein to the coal in the upper part of the producer. The heat is maintained by the combustion of the coke in the lower part of the producer during the periods at which the doors are opened for the withdrawal of coke. In a modification, a small gas-producer is arranged adjacent to the main producer, and flues are provided so that the gases from this producer may be circulated around, or may pass up within, the upper part of the main producer, and so that some of the lighting gas produced may circulate through the small producer and thence through the main producer, after the small producer has been blown with air.—A. T. L.

Gas generating plants; Washing or purifying apparatus for use in —. E. Temple, Sydney, N.S.W. Eng. Pat. 25,736, Nov. 28, 1908.

THE apparatus is of the kind in which a series of buckets on an endless chain passing over rotating chain-wheels, entrap the gas and carry it beneath the water-level in a scrubbing chamber, the gas escaping into the space above the water level in a second chamber communicating with the former below the surface of the water. The invention consists in charging this second chamber with a column of coke, flint, or pebbles up to the water level so as to aid the scrubbing of the gas. A further improvement consists in the provision of a water-lock between the scrubber and the engine. This consists of a closed box or tank with vertical inlet and outlet pipes for the gas extending below the normal water level so as to seal both pipes when the engine is not in use, and a third vertical pipe extending further below the water level and open to the air. When the scrubber is in operation the pressure of the gases forces water from the water-lock up this open pipe, so that the water level is lowered, and the ends of the gas inlet and outlet pipes are unsealed.—A. T. L.

Coal gas; Process for rendering — transportable. A. Menz. Fr. Pat. 402,330, April 23, 1909. Under Int. Conv., April 25 and Aug. 3, 1908.

THE gas is forced into steel bombs at about 200 atmospheres pressure, or the same quantity of gas is introduced into the bomb by compressing at a lower pressure, but at a temperature at which the compressed gas solidifies.—A. T. L.

Mantles; Refractory and indestructible filament for incandescence —. R. Laigle. Second Addition, dated Aug. 1, 1908, to Fr. Pat. 382,749, Oct. 11, 1907 (this J., 1908, 216).

THE patent is for the use, in carrying out the process described in the principal patent, of thorium and cerium oxides having a fibrous structure. These oxides are obtained by impregnating cotton or other fibrous materials with the nitrates, and after drying, burning away the cotton. The waste from incandescence mantles may be used.—A. T. L.

Electric incandescent lamps; Process for fastening the filaments of — to the electrodes. T. McKenna, London. From Glühlampenwerk Anker Ges.m.b.H., Berlin, Germany. Eng. Pat. 20,915, Oct. 3, 1908.

THE ends of metal filaments are coated with the metal of which the leading-in wires consist, and the filaments are then fused to the leading-in wires. The coating of platinum, silver, nickel, copper, iron, or their alloys, may be obtained by electrolytic deposition.—A. T. L.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

Coal-tar; Some constituents of —. II. Pseudocumene. G. Schultz and E. Herzfeld. III. Normal decane. G. Schultz and E. Hartogh. IV. New constituents of solvent naphtha. G. Schultz and A. Perl. V. Normal propylbenzene. G. Schultz and J. Führer. Ber., 1909, 42, 3602–3619.

II.—For the isolation of pseudocumene, Jacobsen's method was followed (Annalen, 1877, 184, 199), a quantity of solvent naphtha (90 per cent. distilling over up to 175° C.) being fractionated so as to obtain 1080 c.c. of distillate boiling between 165° and 170° C., and the latter sulphonated. Pseudocumenesulphonic acid is soluble with difficulty in sulphuric acid and crystallises out. The sulphonic acid thus obtained must however be recrystallised several times from water or dilute sulphuric acid in order to purify it; 1035 grms. of the crude sulphonic acid yielded 410 grms. of the pure acid in the form of colourless rhombic crystals. In order to isolate the hydrocarbon, the sulphonic acid was heated to its melting point (110° C.) and then just when decomposition began to take place, steam at a temperature of 250° C. was passed in, the process being stopped when signs of foaming were observed. In this way 150 grms. of pure pseudocumene were obtained, which boiled at 166° C. at 712 mm. pressure, and had the sp. gr. 0.877 at 18° C. From the hydrocarbon the authors prepared the following derivatives:—Monochloropseudocumene (m. pt. 70° C.), trichloropseudocumene (needles, m. pt. 197° C.), mononitropseudocumene (m. pt. 71° C., b. pt. 265° C.), nitrotrimellitic acid (needles, m. pt. 175° C.), azoxyxypseudocumene (yellow needles, m. pt. 66° C.), dinitropseudocumene, probably $C_6H(CH_3)_2(NO_2)_2[(CH_3)_3C:(NO_2)_2 = 1:2:4:3:5]$, (yellowish needles, m. pt. 171°–172° C.), and trinitropseudocumene (m. pt. 185° C.).

III.—Eleven litres of tar oil (b. pt. 150°–180° C.) which had been previously treated with sulphuric acid in order to separate the pseudocumene and mesitylene as sulphonic acids, were treated repeatedly first with ordinary sulphuric acid and later with sulphuric acid monohydrate. In this way 2320 grms. of an oil were obtained of which 2100 grms. distilled below 200° C., and a further 210 grms. above 300° C. The lower-boiling fraction was treated repeatedly with a mixture of nitric and sulphuric acids, and the final unaltered oil, after washing with alkali and water, was distilled over sodium; it proved to be normal decane, b. pt. 172° C. at 760 mm. and sp. gr. 0.7387 at 15° C. Its mono- and dichloro-derivatives, decyl alcohol, and capric acid were prepared from it.

IV.—By fractionation of a large quantity of solvent naphtha, 4.5 litres of a portion distilling between 153° and 162° C. were obtained, and this was separated into three fractions boiling at 153°–157° C., 157°–160° C., and 160°–162° C. respectively. The first fraction (153°–157° C.) was nitrated, and the crude nitro-product was reduced with stannous chloride and hydrochloric acid. The mixture of amino-compounds was benzoylated and the benzoyl derivatives separated by crystallisation from alcohol into four compounds melting at 115°, 124°, 151°, and 165° C. respectively. Of these, the first and last were identified as the benzoylamino-compounds of *n*-propylbenzene and *p*-ethyltoluene respectively. The two remaining fractions (157°–160°, and 160°–162° C.) were sulphonated in stages, and the different sulphonic acid fractions converted into sulphamides; on sulphonation a portion was left unattacked consisting of *p*-ethyltoluene with some decane. The different sulphamides were identified as derivatives of

mesitylene, *o*-ethyltoluene, *m*-ethyltoluene, and *p*-ethyltoluene. The portion of solvent naphtha distilling between the xylenes and the trimethylbenzenes thus contains *n*-propylbenzene and *o*-, *m*-, and *p*-ethyltoluenes.

V.—Normal propylbenzenesulphonic acid can also be isolated from the mother-liquors obtained in the purification of pseudocumenesulphonic acid (see III., above).

PATENT.

Tar; Methods of purifying —. P. C. Reilly, Indianapolis, U.S.A. Eng. Pat. 22,853, Oct. 27, 1908.

SEE FR. Pat. 395,738 of 1908; this J., 1909, 516.—T. F. B.

IV.—COLOURING MATTERS AND DYE-STUFFS.

Carthamine (Preliminary Note). T. Kametaka and A. G. Perkin. Chem. Soc. Proc., 1909, 25, 223.

CARTHAMINE, the red colouring matter of safflower (*Carthamus tinctoria*), was first isolated by Schlieper (Annalen, 1846, 53, 362) as a red, amorphous powder possessing a cantharides iridescence, and to this he assigned the formula $C_{14}H_{16}O_7$. Radcliffe (J. Soc. Dyers, 1897, 13, 158) obtained carthamine from safflower extract as red, iridescent needles melting at 165° — 169° (provisional), but did not analyse this product. The authors corroborate the work of Radcliffe, but regard the compound he prepared as a salt of carthamine, rather than the free colouring matter itself. They find that the crystalline substance is most readily obtained from the extract by means of pyridine and water, but that an elaborate purification is necessary to obtain a pure compound free from calcium, magnesium, and potassium salts. It forms red, iridescent needles, which, when dried at 110° , are exceedingly hygroscopic and are decomposed at about 228° — 230° . Analyses indicate that the formula of carthamine is probably $C_{14}H_{14}O_7$. On fusion with potassium hydroxide, carthamine gives *p*-hydroxybenzoic acid, as stated by Malin (Annalen, 1865, 136, 117), but in the pure condition the dyestuff appears to be much more stable than has been previously suggested.

Monazo-dyestuffs and their fastness to light; Relation between the chemical constitution of —. E. R. Watson. Chem. Soc. Proc., 1909, 25, 224.

THE author puts forward the theory that the fading in light of an azo-dyestuff is due to the oxidation of that part of the molecule which contains hydroxy- or amino-groups, and that the fastness of such a dyestuff is increased by introducing into the phenolic or arylamino-part such other groups as will reduce the tendency to become oxidised.

Indigo; The action of primary amines on ——. E. Grandmougin and E. Dessoulavy. Ber., 1909, 42, 3636—3641.

WHEN indigo (60 grms.) is boiled with aniline (300 grms.) and anhydrous powdered boric acid (60 grms.) added (the operation requires 3—4 hours), indigodianilide,

is formed. When crystallised from pyridine or xylene it forms dark blue needles which dissolve in xylene, pyridine, nitrobenzene, acetic acid or dimethylamine with a dark blue green colour: the substance is sparingly soluble in ether or chloroform and almost insoluble in alcohol. On oxidation it yields isatin and on reduction a leuco-compound which, however, being insoluble in alkali, is useless for dyeing purposes. Similar compounds are obtained from indigo and the toluidines, *m*-4-xylidine and *m*-2-xylidine. Also 7:7'-dimethylindigo similarly yields an anilide and a toluidide.—J. C. C.

Dehydroindigo; New oxidation product of indigo. I.
L. Kalb. Ber., 1909, 42, 3642—3652.

DEHYDROINDIGO,

is prepared (1) by oxidising indigo with lead peroxide suspended in benzene with the addition of a little acetic acid, (2) by hydrolysing the acetate (O'Neill, Chem. News, 1892, 65, 124; Marchlewski and Radcliffe, J. prakt. Chem., 1898, 58, 102; see this J., 1898, 432) with benzene and pyridine, and (3) by treating a suspension of indigo and calcium hydroxide in chloroform with bromine. Dehydroindigo is an extremely reactive compound of quinone-like character. It crystallises in dark yellowish-red six-sided leaflets with a red brown reflex. It is soluble in most of the common organic solvents and is readily converted into indigo on heating in the air. It is reduced to indigo by stannous chloride or by quinol. On treatment with glacial acetic acid it yields the diacetate referred to above, and readily forms salts with other acids. The author has obtained also 5:5'-dibromodehydroindigo by similar means: this also yields an acetate. (See also page 1192.)—A. C. C.

Amino-derivatives of phenylauramine and rheonine. E. Grandmougin and A. Lang. Ber., 1909, 42, 3631—3635.

THE authors have prepared the following derivatives of phenylauramine: *m*-aminophenylauramine, $C_{23}H_{26}N_4$, bright yellow crystals, m. pt. 198° C.; dimethyl-*m*-aminophenylauramine, $C_{25}H_{30}N_4$, bright yellow crystals, m. pt. 180° C.; diethyl-*m*-aminophenylauramine, $C_{27}H_{34}N_4$, yellow prisms, m. pt. 157° C.; *m*-aminotolylauramine, bright yellow crystals, m. pt. 229° C.; dimethyl-*p*-aminophenylauramine, $C_{25}H_{30}N_4$, deep yellow crystals, m. pt. 179° C.; diethyl-*p*-aminophenylauramine, deep yellow crystals, m. pt. 142° C. By heating dimethyl-*m*-aminophenylauramine with zinc chloride during two hours at 206°—216° C., hexamethylrhoeine (hexamethyltriamino-9-phenylacridine),

is obtained. The zinc chloride double salt forms brown needles with a green reflex and the base dissolves in acids with a deep red colour; the solution in concentrated sulphuric acid is yellow with a green fluorescence.

—J. C. C.

Carbazole derivatives; Some —. P. Ziersch. Ber., 1909, **42**, 3797—3800.

3-NITROCARBAZOLE is conveniently prepared by treating a suspension of carbazole in glacial acetic acid with concentrated nitric acid (sp. gr. 1.38). In this reaction is formed a new nitro-compound which is provisionally called 1-nitrocarbazole. The corresponding aminocarbazoles, obtained by reduction with sodium hyposulphite (hydrosulphite), give red violet dyestuffs when diazotised and combined with naphthol- or aminonaphthol-sulphonic acids. When dinitrocarbazole (Ger. Pat. 46,438) is treated with chlorine in acetic acid solution, a dichloro-derivative is obtained from which the corresponding diamino-compound was prepared. When tetrazotised and combined with naphtholdisulphonic acids, dichlorodiaminocarbazole furnishes violet wool dyestuffs. By nitrating carbazole with fuming nitric acid a tetranitrocarbazole, m. pt. 285° C., identical with one described by Ciamician and Silber (Annalen, 285, 163), results. This on reduction yields a tetra-amino-derivative, of which all four groups can be diazotised. The diazo-compound gives with 2-amino-8-naphthol-6-sulphonic acid a Bordeaux red dyestuff which dyes wool well with the addition of acetic acid and sodium sulphate.—J. C. C.

Colouring of alimentary products. Colours allowed to be used in France. Muttelet. See XVIII A.

PATENTS.

Azo colouring matters [dyestuffs]; Production of —. J. Y. Johnston, London. From Badische Anilin und Soda Fabrik, Ludwigshafen on Rhine, Germany. Eng. Pat. 1816, Jan. 25, 1909. Addition to Eng. Pat. 25,311, Nov. 24, 1908.

INSTEAD of the α -naphtholsulphonic acids mentioned in the chief patent (this J., 1909, 469), 2:3:6-naphthol-disulphonic acid is combined with diazotised benzoyl- p -phenylenediaminesulphonic acid. The lakes prepared from this and similar dyestuffs possess a better covering power than those previously described.—J. C. C.

Halogen-anthraquinones; Process for preparing —. Badische Anilin und Soda Fabrik. Ger. Pat. 214,714, Feb. 26, 1908.

WHEN the halogen-anthraquinonesulphonic acids, prepared according to Fr. Pat. 384,471 (this J., 1908, 442) by the halogenation of anthraquinonesulphonic acids, are treated with halogens or substances producing halogens, in presence of water, the sulphonic acid group is replaced by halogen, resulting in the formation of poly-halogen-anthraquinones.—T. F. B.

Azo dyestuffs; Manufacture of substantive —. O. Imray, London. From Soc. Chem. Ind. in Basle, Switzerland. Eng. Pat. 10,936, May 8, 1909.

Azo dyestuffs which can be further diazotised on the fibre or in substance are obtained by first diazotising a monoazo dyestuff prepared by combining one molecular proportion of an aminobenzoyl-2:5-aminonaphthol-7-sulphonic acid, an aminoaryl-5-hydroxy-1:2-naphthiminazol-7-sulphonic acid, or an aminoaryl-5-hydroxynaphthylthiazol-7-sulphonic acid with one molecular proportion of a monodiazocompound, and then combining the product of the diazotisation with an aminoarylpyrazolonecarboxylic acid. The dyestuffs obtained dye cotton in orange red to blue red shades. By diazotisation on the fibre and combining with β -naphthol, dyes fast to washing are obtained without essential change of tint.—J. C. C.

Blue substantive dyestuffs; Manufacture of —. Act.-Ges. f. Anilinfabr., Berlin, Germany. Eng. Pat. 11,364, May 13, 1909. Under Int. Conv., May 26, 1908.

BLUE disazo substantive dyestuffs are obtained by combining diazotised p -nitro-aniline- o -sulphonic acid with 1:6- or 1:7-naphthylaminesulphonic acid, or a mixture of these acids, or aminocresol methyl ether, again diazotising the azo compound obtained, and then allowing it to act on 2:5-aminonaphthol-7-sulphonic acid or a derivative thereof containing alkyl or aryl substituents in the amino-group.—J. C. C.

Disazo dyestuffs; Manufacture of —. Farbwerke vorm. Meister, Lucius, und Brüning, Höchst on Maine, Germany. Eng. Pat. 12,371, May 25, 1909. Under Int. Conv., July 2, 1908.

THE disazo dyestuffs obtained by combining two molecular proportions of diazotised o -nitroaniline with one of 1:8-aminonaphthol-3:6- (or 4:6-) disulphonic acid—the first molecule of diazo-compound being combined in acid, and the second in alkaline solution—form dark brown powders having a bronze lustre. They give a green solution in sulphuric acid, and dye wool in greenish black shades.—J. C. C.

Disazo dyestuffs; Process for preparing yellowish- to bluish-red —. Farbwerke vorm. Meister, Lucius, und Brüning. Ger. Pat. 214,497, Oct. 27, 1908. Addition to Ger. Pat. 204,102, April 26, 1906.

A DIAZO compound is combined with p -aminobenzoyl-2,5,7-aminonaphtholsulphonic acid; the resulting dyestuff is diazotised, combined with p -nitrobenzoyl-2,5,7-aminonaphtholsulphonic acid, and the nitro-group reduced, e.g., by means of sodium sulphide. The dyestuffs thus obtained dye unmordanted cotton orange to bluish-red shades.—T. F. B.

Sulphur dyestuff. J. Flachslander, Assignor to Farbenfabr. vorm. F. Bayer und Co., Elberfeld, Germany. U.S. Pat. 935,009, Sept. 28, 1909.

A NEW sulphide dyestuff is obtained by heating dinitrochlorophenol ($\text{OH}:\text{NO}_2:\text{NO}_2:\text{Cl}=1:2:4:6$) with sulphur and sodium sulphide to 115°C . for about 16 hours. The dyestuff is precipitated with air. It dyes cotton in black shades.—J. C. C.

Vat [anthracene] dyestuff. P. Thomaschewski, Assignor to Farbenfabr. vorm. F. Bayer und Co., Elberfeld, Germany. U.S. Pat. 935,827, Oct. 5, 1909.

VAT dyestuffs of the anthracene series are obtained by converting an aminoanthraquinone into its derivatives containing a hydroxynaphthylcarbonyl group, $\text{C}_{10}\text{H}_6(\text{OH})\text{CO}$, in the amino-group. Example: 10 parts of 1-aminoanthraquinone are heated to 125°C . with 100 parts of nitrobenzene, 10 parts of 2-naphthol-3-carboxylic acid and 8 parts of thionyl chloride. The condensation product crystallises from the cold liquid in orange yellow prisms. It gives a reddish brown colour with sulphuric acid, and with alkaline hydrosulphite yields a red vat from which cotton, wool or silk is dyed in pure yellow shades.—J. C. C.

Vat [anthracene] dyestuff. L. Wolman, Assignor to Farbenfabr. vorm. F. Bayer und Co., Elberfeld, Germany. U.S. Pat. 935,878, Oct. 5, 1909.

BY treating an aminoanthraquinone with an anthraquinonecarboxylic acid, new substituted aminoanthraquinones are obtained which contain the group, $\text{C}_{10}\text{H}_7\text{O}_2\text{CO}$, in the amino-group. Example: 10 parts of anthraquinone-2-carboxylic acid are heated with 200 parts of nitrobenzene and 6 parts of thionyl chloride to 140°C . After cooling to 100°C , 10 parts of 1-aminoanthraquinone are added and the mixture is heated for 1–2 hours to 110° – 120°C . On cooling, the new product forms yellow crystals. It gives a yellow solution with sulphuric acid and with alkaline hydrosulphite yields a brownish vat from which cotton, wool or silk is dyed in pure greenish yellow shades.—J. C. C.

Azo dyestuffs and their intermediate products; Process for the production of —. Farbenfabr. vorm. F. Bayer und Co. Fr. Pat. 402,030, April 14, 1909. Under Int. Conv., May 18, 1908.

DISAZO dyestuffs are obtained by treating sulphonic or carboxylic acids of aminoazo-compounds of the benzene or naphthalene series which contain no other auxochrome group than the amino-group, with phosgene or its polymerides or with thiophosgene. Example: 962 parts of the sodium salt of the aminoazo-dyestuff prepared from 1-naphthylamine-3:6-disulphonic acid and o -anisidine are dissolved in 9000 parts of water and 600 parts of sodium carbonate, and into this solution a current of phosgene is introduced until the formation of the dyestuff is complete. The dyestuff gives reddish yellow shades on cotton.—J. C. C.

Secondary disazo dyestuffs and their intermediate products; Process for the production of —. Farbenfabr. vorm. F. Bayer und Co. Fr. Pat. 402,120, April 16, 1908. Under Int. Conv., April 22, 1908.

SECONDARY disazo dyestuffs are prepared by combining the diazo-compounds of benzenoid amines which contain a negative group in the ortho-position to the amino-group, or of naphthylamines containing a negative group in the 1- or 2- (ortho) position, with an amine which can later be diazotised. The intermediate product is then diazotised and combined with 2-amino-5-naphthol-7-sulphonic acid or its alkyl or aryl derivatives or substituted derivatives containing the substituent in the ortho-position to the amino-group. The dyestuff obtained from aniline- o -sulphonic acid, p -xylydine, and 2-amino-5-naphthol-1:7-disulphonic acid dyes cotton in reddish violet shades and that from 1-naphthylamine-2:6-disulphonic acid, 1-naphthylamine, and 2-ethylamino-5-naphthol-7-sulphonic acid dyes cotton in bluish violet shades. A list of 32 similar dyestuffs is given in the patent.—J. C. C.

Azo dyestuffs dyeing cotton direct; Process for the production of —. Farbenfabr. vorm. F. Bayer und Co. Fr. Pat. 402,126, April 16, 1909. Under Int. Conv., April 22, 1908.

SECONDARY disazo-dyestuffs are prepared by combining the diazo-compounds of aminoazo-derivatives of the benzene or naphthalene series (except those of peri-aminonaphthol or its sulphonic acids) with the acyl derivatives of 2-amino-5-naphthol-7-sulphonic acid or 2-amino-5-naphthol-1:7-disulphonic acid. Diazotised aminoazobenzene and 2-ethylurethane-5-naphthol-1:7-disulphonic acid, $\text{OH.C}_{10}\text{H}_4(\text{SO}_3\text{H})_2\text{NH.CO}_2\text{C}_2\text{H}_5$, gives a dyestuff which dyes cotton in scarlet shades fast to light. Diazotised aminoazobenzenemonosulphonic acid and 2-benzoylamino-5-naphthol-7-sulphonic acid furnish a dyestuff producing on cotton pure red shades which are fast to light, and the dyestuff obtained from diazotised aminoazobenzenecarboxylic acid and 2-benzoylamino-5-naphthol-7-sulphonic acid dyes cotton red. A list of 40 of these dyestuffs is given in the patent.—J. C. C.

Azo dyestuffs; Process of production of new — and their intermediate products. Farbenfabr. vorm. F. Bayer und Co. Fr. Pat. 402,546, April 30, 1909. Under Int. Conv., May 29 and Oct. 23, 1908.

NEW azo dyestuffs are obtained by combining the diazo-compounds of two molecules of the same or of two different aminodiphenyl ethers or their homologues, or of one molecule of such an ether and one molecule of some other diazo-compound, with one molecule of a peri-aminonaphtholsulphonic acid. The dyestuff obtained from two molecules of diazotised *p*-aminodiphenyl ether and one of 1:8-aminonaphthol-4:6-disulphonic acid dyes wool from an acid bath in blue black shades. The dyestuff prepared by combining diazotised dichloroaniline with 1:8-aminonaphthol-3:6-disulphonic acid in acid solution and then adding one molecule of diazotised *o*-aminodiphenyl ether in alkaline solution, dyes wool from an acid bath in greenish blue-black shades.—J. C. C.

Anthracene compounds and their intermediate products; Process for the production of —. Farbenfabr. vorm. F. Bayer und Co. Fr. Pat. 402,741, May 5, 1909.

NEW anthracene derivatives are obtained by condensing halogenated anthraquinones with thiosalicilic acid or its derivatives and treating the products with dehydrating agents. Example: 154 kilos. of thiosalicilic acid are dissolved in 1250 kilos. of water by means of sodium hydroxide. The solution is mixed with 242.5 kilos. of 1-chloroanthraquinone and heated in an autoclave at 180°–185° C. for twelve hours. After cooling, the mass is diluted, rendered alkaline, boiled and filtered. On acidification, the condensation product separates; it crystallises from alcohol in prisms, m. pt. 246° C. One part of this product is added to 5 parts of melted zinc chloride and the mixture heated for a short time until the precipitate obtained by diluting a sample with water is no longer soluble in sodium hydroxide. The mixture is then heated with water and the precipitate is filtered and washed with warm water. The compound so obtained can be purified by boiling it with dilute sodium hydroxide, water, alcohol and ether. It forms a red powder which gives a yellowish red solution with sulphuric acid and dyes cotton from the hydrosulphite vat in orange shades.—J. C. C.

Vat dyestuffs of the anthracene series; Process for preparing —. Farbenfabr. vorm. F. Bayer und Co. Ger. Pat. 213,500, Aug. 5, 1908.

SUBSTANCES which dye unmordanted cotton red shades from the vat, are obtained by treating benzoylated 1,5-diaminoanthraquinone or its derivatives with concentrated or fuming sulphuric acid, whereby a hydroxyl-group is introduced into the nucleus.—T. F. B.

Triphenylmethane dyestuffs; Process for preparing blue chrome acid —. Anilinfarben- und Extract-Fabr. vorm. J. R. Geigy. Ger. Pat. 213,502, July 19, 1908. Addition to Ger. Pat. 189,938, Sept. 29, 1906 (see Fr. Pat. 384,979; this J., 1908, 497).

THE aldehydes used in the process of Ger. Pat. 199,943 (this J., 1908, 936) are replaced by the following:—*o*-Chloro-*o*-bromobenzaldehyde, 4,6-dibromo-2-chloro-5-aminobenzaldehyde, 2,4,6-tribromo-5-aminobenzaldehyde, 4,6-dibromo-2-chloro-5-hydroxybenzaldehyde. The chromed dyeings produced by these dyestuffs are much greener in shade than those produced by the dyestuffs of Ger. Pat. 199,943.—T. F. B.

Triphenylmethane dyestuffs; Process for preparing acid chrome —. Anilinfarben- und Extract-Fabr. vorm. J. R. Geigy. Ger. Pat. 213,503, Aug. 25, 1908. Addition to Ger. Pat. 189,938, Sept. 29, 1906 (see Fr. Pat. 384,979; this J., 1908, 497).

IN the principal patent and in Ger. Pats. 198,909, 199,943, and 199,944 (this J., 1908, 801 and 936) *o*-hydroxycarboxylic acids are condensed with aldehydes produced from substituted toluene derivatives by the chlorination method, to form leuco-triphenylmethane dyestuffs. These aldehydes may be replaced by the corresponding chlorides, Ar.CHCl_2 , or by the sulphates, obtained by the action of sulphuric acid on the chlorides; these chlorides or sulphates may also be nitrated or sulphonated to obtain corresponding derivatives to those used in the above-mentioned patents.—T. F. B.

Sulphonation of organic compounds. F. Thümmeler. Ger. Pat. 214,156, Feb. 4, 1909.

SALTS of vanadium are used as catalytic agents in the sulphonation of organic compounds. For example, 100 grms. of anthraquinone are treated with 80 grms. of fuming sulphuric acid (60 per cent. anhydride) in presence of 0.1 to 0.2 gm. of vanadium sulphate, for one hour at 170° C. In that time, 86 grms. of the anthraquinone will have been sulphonated.—T. F. B.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS AND FIBRES.

Cotton: Presence of iron in mercerised — L. Lefèvre and E. Biondel. Rev. Gen. Mat. Col., 1909, 13, 313—314.

THE ash of raw Egyptian cotton ("Maco") contains 1.5 per cent. of iron oxide, whereas the ash of the same cotton after mercerisation was found to contain 8 per cent. In neither case have such minute quantities any influence on the colour of the yarn. The circumstance that the "écru" colour of the cotton is deepened by mercerisation is due to the action of the alkali on the organic colouring matters. The increase in the iron-content of the cotton, as the result of mercerisation, is explained by the authors in the following manner: The concentrated lye dissolves from the cotton a certain quantity of pectic matters and soluble forms of cellulose, during the passage of the yarn or fabrics; and this solvent action is even more pronounced in the process of hot washing. These organic matters, like other hydroxylated bodies, possess the property of holding ferric oxide in alkaline solution. Consequently, the rust which may form on the tanks or parts of the machinery is dissolved by the lye and absorbed by the cotton. This solvent action is particularly marked in factories where the dilute washings are utilised for the preparation of fresh lye. In fact it is frequently necessary to use these contaminated lyes for other purposes, in order to economise the quantity of acid required to remove the iron oxide absorbed by the cotton. The concentration of the "sours," usually employed for clearing the chalk and last traces of alkali from the cotton, is too weak to have any effect on the iron oxide absorbed under the above conditions.—J. F. B.

Wool: The properties of — and the hydrolytic changes occurring during dyeing. W. Snida. Z. angew. Chem., 1909, 22, 2131—2134.

KERATIN is closely allied to the representative albuminoids, but slight differences are noticeable in keratin from different sources, or even from one and the same source, according to the age, feeding, or state of health of the animal producing it. In preparing wool for experimental investigations, it is important to remember that purification should only be carried out by treating with volatile solvents (for fats) and lukewarm water and that

the use of hot water, alkalis and acids, should be avoided. To most reagents, in the cold, wool is an indifferent substance, but with rise of temperature, hydrolytic decomposition begins and the basic character of the wool becomes more pronounced the further the hydrolysis proceeds. Wool possesses amphoteric properties, with a tendency towards basicity, and therefore for dyeing it, acid dyestuffs are the most suitable. Experiments show (1), that from a neutral bath wool is hardly dyed at all by the salts of colour acids; (2), that the free colour acids are readily taken up from such a neutral bath (3), in an acid bath the salts of colour acids also dye the wool; (4), basic dyestuffs (which are usually the hydrochlorides of colour bases) dye readily from a neutral bath; but (5), in an acid bath they have very little effect upon the wool. Should the dyeing properties depend upon interaction between acid or basic groups in the wool and the colour acids and bases, case (1) could be explained upon the assumption that the acid groups of the wool are incapable of decomposing the colour salt, whilst in case (2) the basic groups combine directly with the free colour acid. In case (1) it may be assumed that the basic portion of the wool combines with the hydrochloric acid of the colour salt, whilst the acid portion unites with the colour base, but it must not be forgotten that a pronounced hydrolysis evident also in case (3)—is noticeable. The result in case (5) may be explained by assuming that the free acid hydrolyses the wool substance and saturates the basic groups, thus preventing the dissociation of the colour salt. Many salts and esters have a similar influence in preventing the dyeing of wool with basic dyestuffs, without interfering with its affinity for acid dyestuffs, and the more pronounced the acidic nature of the salt, etc., may be, the greater is its influence. Should the hypothesis be correct, that the colour acid is capable (by formation of an insoluble combination with the basic groups of the wool) of displacing a mineral acid, then by first treating the wool with an acid which produces an insoluble combination, it should be rendered incapable of being dyed by acid dyestuffs in the ordinary manner. Experiments with metatungstic and phosphotungstic acids show that such is indeed the case. In general, the author's results show that in the mordanting and dyeing of wool with acid mordants or direct (acid) dyestuffs, there is an initial hydrolysis of the wool, followed by the formation of a more or less insoluble compound by the union of its active groups with certain components of the mordant or dyestuff. Since by the hydrolysis of albuminoids the more resistant portion retains the basic groups, it is explicable why in the hydrolysis of wool, acid dyestuffs produce precipitates after basic dyestuffs have ceased to do so, and that dyeings produced with acid dyestuffs are in general more solid than those produced with basic ones.—F. M.

Dehydroindigo. II. Dehydroindigo bisulphite and a new process of indigo dyeing. L. Kalb. Ber., 1909, 42, 3653—3664. (See page 1189.)

DEHYDROINDIGO sodium bisulphite, $C_{16}H_8N_2O_2 \cdot 2NaHSO_3$, is prepared either from dehydroindigo and aqueous bisulphite solution or from dehydroindigo salts by double decomposition with the normal sulphite. It is a well-crystallised salt, having a canary yellow colour and an intensely sweet taste. With alkalis it yields indigo and with reducing agents it yields indigo or indigo white. With bromine and chlorine it yields the corresponding 5:7:5':7':tetrahalogenated derivatives. A new method of producing indigo dyeings is afforded by steeping the fibre (or printing it) with an aqueous solution of dehydroindigo bisulphite, drying, and dipping the fibre into dilute mineral acids, alkali carbonates or hydroxides at 80°—100° C. Indigo is at once produced on the fibre. Good dyeings are obtained with cotton and silk, but not with wool. After dyeing, the goods are passed through an appropriate bath of acid or alkali and finally washed. The tetrahalogenated compounds of dehydroindigo are extremely sensitive to light and this property may be used to obtain photographs by using paper impregnated with them as a printing paper. After exposure, a positive is produced in tetrachloro- or tetrabromo-indigo. For fixing, the paper is washed with water.—J. C. C.

Dyeing; Theory of — in practice. G. Friedländer. Chem.-Zeit., 1909, 33, 1159.

A LARGE number of benzidine dyestuffs alter their shades under the influence of dry heat. Red dyestuffs become more yellowish, yellow dyestuffs bluer, and blue dyestuffs redder on ironing, the reverse change taking place on cooling. On comparing the constitution of those substantive dyestuffs which are fast with those which are not fast to ironing, it was found that the latter are characterised by containing a relatively large number of sulphonic groups. Investigations were also instituted regarding the general constitutional characteristics of those substantive dyestuffs which dye the cotton in half-silk tissues, but leave the silk white. As a result the rule is formulated that such benzidine dyestuffs as contain one or two amino-groups and are of a relatively strongly sulphonic acid nature, e.g., Diamine Black BH (from benzidine, γ -aminonaphtholsulphonic acid, and aminonaphtholdisulphonic acid H) will prove the best representatives of this group. Various benzidine dyestuffs containing as components only hydroxynaphthalenesulphonic acids, e.g., Brilliant Azurine B (from dianisidine and dihydroxynaphthalenesulphonic acid S) show the same property, but, in general, in a lesser degree. This is accounted for by the fact that an amino group produces in a dyestuff of this class a superior affinity for cotton, while the sulphonic groups tend to prevent the dyeing of the silk. The same principle obtains with regard to half-wool, *viz.*, that it is those substantive dyestuffs of a strongly sulphonic acid character which will leave the wool least stained, but, owing to the strongly basic nature of this fibre, a small portion of the dyestuff is attracted to it and staining results. The author regrets the small choice of dyestuffs available to the half-silk dyer which dye cotton and leave the silk white. He enumerates the principal members of this group, giving the constitution of several and deducing the afore-mentioned rules therefrom. Deep Bordeaux, full brown, and bright dark blue self dyestuffs of the above class are, he thinks, desiderata yet to be put on the market.—J. L. H.

Carbon, amorphous; Decolorising properties of different kinds of —. L. Pelet and C. Mazzoli. Bull. Soc. Chim., 1909, 5, 1011—1019.

THE authors determined the adsorptive power for Methylene Blue and Crystal Ponceau of a number of different commercial samples of amorphous carbon, including blood charcoal, animal charcoal, bone charcoal, wood charcoal, lampblack, and three specimens of the decolorising carbon of the Stassfurter Chem. Fabr. vorm. Vorster und Grüneberg, marked RT, ETB, and ET respectively. The values obtained were referred to 100 grms. of the organic matter of the charcoal, since it was found that the mineral constituents (calcium carbonate and phosphate, ferric oxide, etc.), possess no adsorptive power. Samples of the charcoals were then treated in the following ways:—(1), washed for a long time with hot distilled water; (2), heated repeatedly for several hours with concentrated hydrochloric acid; (3), heated for 3 hours with concentrated sulphuric acid, in order to destroy any cyanogen groups that might be present; (4), heated for 3 hours with a concentrated solution of sodium hydroxide in order to eliminate the whole or a part of any amino-groups present; (5), treated with sodium nitrite and hydrochloric acid and then heated to boiling, in order to destroy any amino-groups. In every case the treated charcoal was washed thoroughly with water, until the electrical conductivity of the wash-water remained approximately constant; this was essential since electrolytes even in traces have considerable influence on adsorption. On again determining the adsorptive powers of the charcoals after the treatments, it was found that these had not been sensibly modified. The exceptions noted in the case of charcoal treated with caustic soda are attributed to retention of alkali by the charcoal, since when after the treatment the first washing was made with dilute hydrochloric acid, the differences were diminished. The authors conclude that there is no relation between the adsorptive power of charcoal and the presence in the latter of nitrogen (compare

Knecht, this J., 1909, 700) or of chemically active nitrogenous groups (compare Glassner and Suida, this J., 1907, 1195).—A. S.

Wool gelatin and animal size; Method of distinguishing between —. A. Herz and C. E. Barraclough. J. Soc. Dyers and Col., 1909, 25, 274—276.

ANIMAL fibres in general were found on boiling to yield a water-soluble substance which gave the tannin and biuret reactions for gelatin. These tests therefore did not afford a means of distinguishing between wool or hair material unsized and a similar material sized with glue or gelatin, except in cases where the sizing was very heavy. But it was found that solutions of lead acetate and of basic lead acetate precipitate the wool gelatin from solution but do not affect solutions of ordinary glue or gelatin; these reagents the authors therefore consider the most suitable for distinguishing between the two kinds of gelatin. They recommend the use of the tannin-salt reaction as a second test. A list of the actions of various reagents on wool gelatin and ordinary gelatin is given. Wool gelatin precipitates basic dyestuffs, with which it forms lakes; but with acid and direct dyestuffs no such combinations are formed. Further experiments seemed to show that wool gelatin consists of three substances: (1), one which is not precipitated by Night Blue but which is precipitated by the tannin-salt reagent (a filtered mixture of 100 c.c. of a 2 per cent. solution of tannin and 100 c.c. of a saturated solution of salt); (2), one which is precipitated by Night Blue and on this precipitate being decomposed with barium hydroxide goes into solution, and after removal of excess of barium hydroxide is again capable of precipitation either by Night Blue or tannin-salt; (3), one which is precipitated by Night Blue but on decomposing the precipitate with barium hydroxide, remains insoluble and mixed with the insoluble Night Blue base.—S.H.H.

Preparing viscose. Todtenhaupt. See XIX.

PATENTS.

Ramie, China grass, and other fibrous substances; Treatment of —. L. H. Raw and R. G. Orr, London. Eng. Pat. 20,173, Sept. 25, 1908.

THE raw material is thinly spread out and pressed down on to bare and levelled ground which should contain the normal quantity of moisture. At intervals of a few days the material is turned over and again pressed down. This treatment is continued until it is found by trial that a dried sample readily disintegrates on shaking and allows of the ready separation of the fibres. For China grass a treatment of 8—10 days is usually sufficient.

—P. F. C.

Ramie and other similar substances; Treatment of —. R. Sumner, Horton, Bucks. Eng. Pat. 21,536, Oct. 12, 1908.

THE raw material is spread out in a trench about a foot deep and covered with three to five inches of earth for a few days. The period of treatment is varied according to the condition of the raw material and the nature of the desired product. (Reference is directed to Eng. Pat. 8288 of 1907).—P. F. C.

Vegetable fibres contained in straw, grasses, bast, "hurd" and the like; Process for obtaining and preparing for spinning and weaving purposes the —. F. A. Reichmann, Barmen, Germany. Eng. Pat. 12,059, May 21, 1909.

THE material to be treated, thrashed rye-straw for example, is boiled with a solution of sodium hydroxide of $\frac{1}{2}^{\circ}$ B. until the gliadin is dissolved and the straw readily divides up into its fibres. The dirty lye is then run off and a cold solution of sodium or potassium hydroxide of at least 15° B. is poured over the fibre. This causes the individual fibres to curl and separate from one another. After two or three minutes the lye is removed and the material is washed and then treated with a solution of hydrofluoric acid of 1° — 2° B. in a wooden or leaden

vessel for about five hours. The fibres are finally washed with water to which small quantities of ammonia and magnesium chloride are added and are then dried.—P. F. C.

Artificial hair or silky threads; Manufacture of — G. B. Ellis, London. From Le Crinoid Soc. Anon., Rouen, France. Eng. Pat. 21,191, Oct. 7, 1908.

THE concentration of the caustic alkali solution (employed in the coagulation of the solution of cellulose in cuprammonium hydroxide) is of importance, it having been found that with a low concentration the coagulation is not complete; with too strong a solution however the thread, after formation, tends to become brittle and is irregular in form owing to the capillary tubes of the spinneret becoming blocked. The latter faults are obviated by adding sodium carbonate to the bath (which should contain 50 per cent. of caustic soda and 25 per cent. of sodium carbonate) and maintaining the temperature of the same at about 35° C. The threads are passed through a second, weaker bath and then through a solution of sodium bisulphate (to remove the excess of copper hydroxide), after which they are washed and dried.—F. M.

Radiform fibres and the process of producing them. H. Farjas and A. Jaboin, Paris. Eng. Pat. 14,760, June 23, 1909. Under Int. Conv., Dec. 4, 1908.

THE fibres are cleaned, dried, then placed in a suitable mordanting solution such as for example a 10 per cent. solution of tannin or a concentrated solution of alum and then dried again. In the first case, they are next immersed in a 2 per cent. solution of ammonia at 22° C., in the second case in water. They are dried once more and placed in a solution of a radium salt the concentration being determined by the degree of radioactivity it is desired to obtain. After remaining in the solution for about half an hour, the fibres are removed and dried.—P. F. C.

Bleaching and otherwise treating fabrics with liquids; Method of and apparatus for — H. L. Gantt, Pawtucket, Rhode Island, U.S.A. Eng. Pat. 16,429, Aug. 4, 1908.

THE apparatus consists of a tank which is provided with a partition reaching almost to the bottom. The fabric to be treated is plaited lattice-wise in rope form into the space between the partition and one of the walls but is prevented from falling below the partition by a supporting arm. This arm is so hinged on to the wall of the tank that sufficient space is just left between its free end and the bottom of the partition for the withdrawal of the fabric from the bottom of the pile. This withdrawal is effected at the same rate as the fabric is delivered into the apparatus, by means of a pair of squeezing rollers arranged inside the tank between the partition and the other wall. These rollers lead the fabric to a second pair of squeezers arranged outside the tank and provided underneath with a trough which collects the expressed liquor and re-delivers it into the apparatus. The liquor is circulated through the pile of cloth by means of a pump, steam being delivered into the circulating pipe to maintain the necessary temperature.—P. F. C.

Dyeing, bleaching, washing or similarly treating textile fabrics or other materials or substances. J. W. Balme and C. H. Ashton, Halifax. Eng. Pat. 21,621, Oct. 13, 1908.

A VESSEL is built-upon the same lines as an ordinary jigger but using glazed earthenware or fireclay instead of wood. Instead of having a copper steam pipe for heating purposes, a hollow passage is moulded in the lower part of the apparatus, one end being capable of attachment to a steam supply. The walls of this passage are perforated. The rollers are made of blocks of glazed earthenware provided with a central opening for the passage of a shaft.—P. F. C.

Rollers for use in dyeing, bleaching, and like machines. J. W. Balme, Halifax. Eng. Pat. 4626, Feb. 25, 1909.

THE roller comprises an earthenware or porcelain shell, provided on its interior surface with two diametrically

opposed longitudinal projecting tongues which extend nearly from end to end of the shell. Two semi-circular longitudinal wooden cores are so grooved that they can fit on to these tongues whilst their meeting faces are also grooved to accommodate a shafting. In building up a roller, the wooden supports are clamped together at each end by means of annular metal rings, which are sunk into their ends. They are then placed inside the shell and the shaft is pushed through the opening provided for it. Wedges are driven in between the shaft and the annular rings. Any gaps remaining are filled up with liquid cement.—P. F. C.

Dyeing and dyes [dyestuffs] for use therein. C. Fowler, Bradford. Eng. Pat. 1920, Jan. 26, 1909.

FOR dyeing union goods two colours in one bath, a combination is employed of a direct cotton dyestuff with alizarin or mordant dyestuffs of a different shade. With these colours the following substances may be employed:—inorganic acid salts; organic or inorganic salts which dissociate and liberate acids, such as ammonium acetate; chromium, iron, copper, aluminium or zinc salts and organic or inorganic acids. Example:—1 part of Chlorazol Fast Yellow B, 3 parts of Alizarin Blue S and 5 parts of sodium acid sulphate are mixed and the mixture is used for dyeing union goods, one part of potassium bichromate being preferably added to the dye-bath after boiling for half an hour.—P. F. C.

Acetylcellulose; Process for dyeing — Knoll und Co. Addition, dated Apr. 5, 1909, to Fr. Pat. 383,636, Nov. 6, 1907 (this J., 1908, 332).

IN a variation of the principal patent, acetylcellulose is treated with aqueous solutions of inorganic acids instead of with organic substances or their solutions, in order to make it capable of absorbing dyestuffs and dye-forming substances more readily. This treatment with inorganic acids has also the effect of swelling the fibre and increasing its elasticity without any accompanying hydrolytic dissociation. It is necessary to eliminate all traces of the acid from the fibre after treatment and to dye the fibre before drying.—H. P. P.

Turkey-red; Process for dyeing close and heavy pieces by means of — Eitorfer Türkischrot-Stückfärberei. Fr. Pat. 402,032, April 14, 1909.

THE pieces after passing several times through Turkey-red oil, are guided full width through the alizarin dye-bath where they are subjected to a pounding or beating, which causes the liquor to penetrate, forming the lake throughout the fabric. They are then returned to the oil bath. In the case of fustians, twill, etc., which are mercerised, the beating process follows the dyeing.—H. P. P.

Silk; Process for weighting — by means of a mixture of stannic chloride and zinc salts. H. Salvaterra. Ger. Pat. 214,372, Sept. 20, 1907.

SILK is degummed and washed in the usual manner, and is then digested for an hour in a solution obtained by mixing stannic chloride solution of 30° B. with zinc sulphate solution of 30°–45° B.; the proportions may vary, but it is mentioned that equal parts can be used with advantage. The excess of solution is removed in a centrifugal or similar apparatus, and the silk is immersed in a solution of tartaric acid of such strength that no turbidity is produced; it is then washed with water, treated at 75° C. in a solution of sodium phosphate of 5°–8° B., centrifuged, and washed. The process is repeated until the desired increase in weight is reached. It is stated that the elasticity and strength of the fibres remains practically unaltered by this method.—T. F. B.

Silk weighted with stannic chloride; Process for increasing the stability of — E. Herzog. Ger. Pat. 213,471, May 13, 1908.

AFTER long exposure to sunlight, the tensile strength and elasticity of silk weighted with tin decrease to a considerable extent. This can be avoided if an alkali thiosulphate (e.g., 10 per cent. on the weight of the silk) be added to the dye-bath, or to the brightening bath, or to both.—T. F. B.

Yellow dyeings on un mordanted vegetable fibres; Process for producing —. Farbenfabr. vorm. F. Bayer und Co. Ger. Pat. 213,473, June 5, 1908.

THE leuco-compound obtained by alkaline reduction (e.g., by hydrosulphite) of dibenzoyl-1,5- or -1,8-diaminoanthraquinone, is used as a vat for impregnating un-mordanted vegetable fibres; after immersion for about an hour, the fibres are exposed to the air, washed, soured, washed, soaped, and dried. Fast golden-yellow shades are thus produced.—T. F. B.

Dyeings with sulphide dyestuffs; Process for treating —. R. vom Hove. Ger. Pat. 214,038, Oct. 15, 1908. Addition to Ger. Pat. 204,442, Oct. 9, 1907.

THE process described in the chief patent (this J., 1909, 58) for increasing the fastness to soaping of black dyeings with sulphide dyestuffs, is equally applicable to sulphide dyeings of other shades.—T. F. B.

Sizing composition. M. Rossi, Cervignano, Austria-Hungary. U.S. Pat. 937,095, Oct. 19, 1909.

A SIZING composition for textile fabrics consists of about 100 parts of the product resulting from the action of sulphur dioxide on wet starch and about 30 parts of a soap-like compound of ammonia and an unsaturated fatty acid.—H. P. P.

Printing and dyeing textiles; Process and apparatus for —. F. Ashton. Fr. Pat. 402,105, April 16, 1909. Under Int. Conv., April 18, 1908.

SEE Eng. Pat. 8620 of 1908; this J., 1909, 519.—T. F. B.

Ramie and other fibres; Process for rendering — water-repellent and for permanently colouring them without the use of dyestuffs. A. M. Hart. Fr. Pat. 402,415, April 26, 1909.

SEE Eng. Pat. 13,020 of 1908; this J., 1909, 472.—T. F. B.

Preparing formaldehydesulphoxylates from nitrogen-derivatives of methylsulphoxylates. Ger. Pat. 214,043. See VII.

solution, at least 1 grm. of free ammonia is liberated per 100 c.c. of solution; otherwise an appreciable amount of calcium carbonate, etc., will be dissolved. If the method is applied to substances containing only small quantities of caustic lime in presence of large quantities of calcium carbonate, at least 1 grm. of free ammonia should be added to 100 c.c. of the ammonium chloride solution used. A still larger excess of free ammonia further decreases the solubility of calcium carbonate in ammonium chloride solution.—J. L. H.

Sodium carbonate and sodium thiosulphate; Spontaneous crystallisation of solutions of —. B. M. Jones. Chem. Soc. Trans., 1909, 95, 1672—1683.

SUPERSATURATED solutions of sodium carbonate, free from crystal nuclei, are found to crystallise at definite temperatures when slowly cooled (or in some cases heated) and subjected to mechanical friction, and supersolubility curves have been traced, giving the temperature of spontaneous crystallisation of supersaturated solutions of varying strengths and showing the conditions under which ice and the compounds, $\text{Na}_2\text{CO}_3 \cdot 10\text{H}_2\text{O}$ and $\text{Na}_2\text{CO}_3 \cdot \text{H}_2\text{O}$, are formed; these curves lie very roughly parallel to the solubility curves. The less stable hydrate, $\text{Na}_2\text{CO}_3 \cdot 7\text{H}_2\text{O}$, is rarely produced, the conditions favouring its formation occurring only between narrow limits of concentration, and even in such solutions there is an almost equal tendency to produce the decahydrate. Supersaturated solutions of sodium thiosulphate, containing 0—40 and 179—255 parts of anhydrous salt to 100 parts of water, also crystallise at definite temperatures, and supersolubility curves are given for ice and the monohydrate, $\text{Na}_2\text{S}_2\text{O}_3 \cdot \text{H}_2\text{O}$ (secondary). Of the 14 possible solid phases these are the only two which crystallise spontaneously, within the space of one or two hours, from supersaturated solutions which are slowly cooled and constantly shaken, but the anhydrous salt, the primary dihydrate, $\text{Na}_2\text{S}_2\text{O}_3 \cdot 2\text{H}_2\text{O}$, the secondary pentahydrate, $\text{Na}_2\text{S}_2\text{O}_3 \cdot 5\text{H}_2\text{O}$, and the ordinary (primary) pentahydrate have been obtained from solutions kept at rest for longer periods.—F. SODX.

Carbonates of some heavy metals. K. Feist. Arch. Pharm., 1909, 217, 439—447.

SATISFACTORY results for the preparation of carbonates of the heavy metals can be obtained by the addition of water to a mixture of a salt of the metal and sodium carbonate in suitable proportions. Basic zinc carbonate was prepared by powdering together 100 grms. of crystallised zinc sulphate and 120 grms. of sodium carbonate crystals, water was then added, and the precipitate collected and washed with cold water. It had approximately the composition, $\text{ZnCO}_3 \cdot \text{Zn}(\text{OH})_2$. A mixture of 100 grms. of copper sulphate crystals with 140 grms. of sodium carbonate crystals gave a basic copper carbonate which generally contained traces of basic copper sulphate. Equal weights of lead acetate and sodium carbonate crystals, when treated in the same way, gave a basic lead carbonate, which differed very little in its composition from that of normal lead carbonate. The basic carbonates of aluminium and iron can be prepared by similar reactions and give products which serve as the starting point for the production of other salts of these metals.—F. SODX.

Silver sulphite; Action of heat on —, and on the alkali-silver sulphites. H. Banbigny. Comptes rend., 1909, 149, 735—737.

THE statement is commonly found in text-books that silver sulphite and the alkali-silver sulphites, heated to 100° C. or boiled with water, form metallic silver, sulphate, and sulphur dioxide. The real fact is that dithionate is formed under these circumstances, and that only when the temperature is further raised, does this decompose into sulphate and sulphur dioxide.—J. T. D.

Salts in non-aqueous solutions; Reactions of —. A. Naumann. Ber., 1909, 42, 3789—3796. (See also this J., 1904, 1088, and 1905, 26).

THE following salts are soluble (those marked * with difficulty or sparingly) in methyl acetate: Potassium

VII.—ACIDS, ALKALIS, SALTS, AND NON-METALLIC ELEMENTS.

Pyridine in "aqueous ammonia" [ammonia solution]; Determination of —. A. C. Houghton. J. Ind. and Eng. Chem., 1909, 1, 698—700.

THE determination of pyridine in ammonia solution is of importance to manufacturers of anhydrous ammonia for refrigerating purposes, as it causes considerable trouble in the ammonia-compressors. The following method has been used in practice for several years and is said to give accurate results. 100 c.c. of the ammonia solution are diluted with 150 c.c. of distilled water, then rendered neutral to methyl orange by means of dilute (1:3) sulphuric acid, and after adding 5 c.c. of N/1 caustic soda, distilled. The vapours are passed through 100 c.c. of a solution of sodium hypobromite (25 c.c. of bromine added to a solution of 100 grms. of caustic soda in 1000 c.c. water), and then into N/10 acid. The ammonia is decomposed by the hypobromite solution, with formation of nitrogen, so that only pyridine is absorbed by the acid, and titration of the excess of acid gives the necessary data for calculating the amount of pyridine present.—A. S.

Caustic lime, etc.; Determination of — in the presence of calcium carbonate. Heyer. Chem.-Zeit., 1909, 33, 1157—1158.

THE process for the determination of oxides, hydroxides, succrates of alkaline-earth metals in presence of carbonates, phosphates, sulphates, etc. of the same, which depends on treatment with a cold dilute aqueous solution of ammonium chloride, and subsequent determination of the dissolved lime, results sufficiently accurate for technical purposes can be obtained only if the substance contains so much caustic lime that on adding the ammonium chloride

thiocyanate, iodide,* permanganate*: Sodium iodide, thiocyanate; Lithium bromide, chloride,* iodide, thiocyanate; Rubidium iodide; Ammonium thiocyanate; Barium iodide, bromide*: Strontium bromide; Calcium nitrate, bromide; Magnesium bromide,* iodide*: Cuprous bromide,* chloride,* iodide; Cupric bromide, chloride, thiocyanate; Zinc bromide, chloride, iodide, nitrate; Lead iodide*: Cadmium bromide,* iodide; Cerie chloride*, bromide; Chromium trichloride,* trioxide; Manganous chloride*: Ferrous chloride; Ferric chloride*: Cobalt bromide, chloride, iodide, nitrate, thiocyanate; Nickel chloride,* nitrate*: Thallous iodide*: Thallie chloride*: Uranium bromide, nitrate; Uranyl chloride, iodide; Bismuth chloride, iodide; Stannous chloride; Stannic iodide; Silver nitrate,* arsenite; Mercurous iodide,* nitrate; Mercuric chloride, bromide, iodide, cyanide, potassium iodide; Auric bromide; Platinic chloride*: Palladium iodide; Iodine; Sulphur.* The following are insoluble:—Potassium chloride, chlorate, perchlorate, carbonate, bicarbonate, nitrate, nitrite, sulphate, bisulphate, anhydrosulphate (pyrosulphate), fluoride, bromide, bromate, iodate, periodate, cyanide, sulphide, silicate, silicofluoride, chromate, pyrophosphate, ferrocyanide, ferri-cyanide, pyroantimonate, hydroxide; Sodium chloride, chlorate, bromide, bromate, iodate, periodate, fluoride, nitrate, nitrite, carbonate, bicarbonate, anhydrosulphate, sulphate, sulphite, bisulphite, phosphate, pyrophosphate, silicate, silicofluoride, molybdate, tungstate, hydroxide; Lithium fluoride, iodate, carbonate, sulphate, metaborate, pyroborate, phosphate, silicate, silicofluoride, hydroxide; Cesium chloride, sulphate; Rubidium chloride, bromide, nitrate, sulphate; Ammonium chloride, bromide, nitrate, sulphate; Barium chloride, chlorate, bromate, cyanide, sulphate, sulphite, dithionate, nitrate, carbonate, tetraborate, chromate, phosphate, oxide; Strontium chloride, carbonate, metaborate, nitrate, sulphate, sulphide, oxide; Calcium chloride (?), fluoride, carbonate, sulphate, sulphite, tetraborate, phosphate, silicate, sulphide, oxide; Magnesium chloride, fluoride, sulphate, bisulphate, carbonate, silicate, arsenate, oxide; Cuprous thiocyanate; Cupric fluoride, cyanide, nitrate, sulphate, carbonate, phosphate, silicate, silicofluoride, sulphide, borate, arsenate, Zinc fluoride, cyanide, carbonate, sulphate, phosphate, oxide; Lead chloride, bromide, nitrate, sulphate, phosphate, silicate, basic carbonate; Cadmium chloride, carbonate, sulphate, oxide; Chromium fluoride, carbonate, sulphate, phosphate; Erbium sulphate; Manganous carbonate, sulphate, phosphate; Ferrous sulphate, sulphide; Ferric sulphate; Cobalt cyanide, sulphate, carbonate, phosphate, arsenate; Luteo- and Purpureo-cobalt chlorides; Nickel cyanide, sulphate, phosphate; Thallous chloride, bromide, carbonate; Bismuth sulphate; Aluminium potassium sulphate; Stannic sulphide; Silver chloride, bromide, iodide, iodate, nitrate, cyanide, thiocyanate, carbonate, sulphate, phosphate; Mercurous chloride, bromide; Mercuric sulphate; Palladic iodide. The solutions of iodides are at first clear and colourless, but become gradually yellow and brown from separation of iodine.

Potassium thiocyanate reacts with sodium iodide, forming a precipitate of potassium iodide; using excess of sodium iodide, the whole of the potassium is precipitated. With lithium nitrate, a precipitate of potassium nitrate falls, but the precipitation is never complete.

Cobalt chloride: 1 grm. dissolves in 271 grms. of the acetate, giving a blue solution, from which traces of water precipitate on the glass vessel a red deposit of textile-like appearance. The solution with potassium thiocyanate precipitates (completely, if the cobalt solution be in excess) potassium chloride. With lithium nitrate, lithium chloride falls, but some lithium always remains in solution. Dry ammonia, passed into the cobalt solution, gives a rose-red precipitate of composition represented by the formula, $\text{CoCl}_2 \cdot 6\text{NH}_3$.

Cobalt bromide dissolves to the extent of 1 grm. in 9.7 grms. of the acetate. It precipitates potassium completely as bromide from the thiocyanate. With ammonia it yields a compound, $\text{CoBr}_2 \cdot 6\text{NH}_3$, which at 120°C gives off ammonia, leaving the substance, $\text{CoBr}_2 \cdot 2\text{NH}_3$. Hydrogen sulphide produces hardly any effect on the cobalt bromide solution, but a mixture of hydrogen

sulphide and ammonia precipitates the cobalt completely as sulphide, leaving ammonium bromide in solution.

Cupric chloride: 1 grm. dissolves in 181 grms. of the acetate. Stannous chloride forms cuprous chloride which precipitates. Ammonia gives the compound, $\text{CuCl}_2 \cdot 6\text{NH}_3$, which at 135° forms the compound, $\text{CuCl}_2 \cdot 2\text{NH}_3$. Hydrogen sulphide precipitates cupric sulphide.

Mercuric chloride: 1 grm. dissolves in 2.35 grms. of methyl acetate. Precipitates potassium or ammonium chloride, but not completely, from the corresponding thiocyanate, barium chloride completely from the iodide. Its chlorine can be completely precipitated as potassium chloride, by excess of potassium-mercuric iodide. Ammonia yields the compound, $\text{HgCl}_2 \cdot 2\text{NH}_3$, hydrogen sulphide gives the compound, $\text{HgCl}_2 \cdot 2\text{HgS}$, and a mixture of the two gives mercuric sulphide. Stannous chloride in deficit precipitates calomel, in excess metallic mercury.

Mercuric bromide: 1 grm. dissolves in 4.56 grms. of the ester. With ammonia, hydrogen sulphide, and a mixture of the two, it behaves analogously to the chloride.

Calcium nitrate: 1 grm. dissolves in 1.44 grms. of methyl acetate. Hydrochloric acid gas produces a precipitate having the composition represented by $\text{CaCl}_2 \cdot \text{CH}_3\text{COOCH}_3$. Neither mercuric chloride, stannous chloride, zinc chloride, cupric chloride, nor cobalt chloride produces any precipitate.

Calcium chloride: This salt does not dissolve in methyl acetate, but when shaken with it, produces the compound described above, $\text{CaCl}_2 \cdot \text{CH}_3\text{COOCH}_3$.—J. T. D.

Chlorine and hydrogen: Influence of gaseous oxides of nitrogen on the rate of interaction of —. D. L. Chapman and P. S. MacMahon. Chem. Soc. Proc., 1909, 25, 224.

It was shown that the brown gas resulting from the interaction of nitric oxide and chlorine—presumably nitrogen peroxide—inhibits the union of hydrogen and chlorine in the light. The inhibitor is slowly absorbed by the chlorine water in the actinometer, and as it is removed, the electrolytic gas gradually recovers its original sensitiveness; the removal of the last trace of inhibitor appears to be facilitated by the action of light. The retardation observed with nitrous oxide was so small that the authors conclude that this gas behaves as a diluent only. In this respect it resembles nitrogen and carbon dioxide.

Bismuth trisulphide; Solubility of — in alkali sulphides, and of bismuth trioxide in alkali hydroxides. J. Knox. Chem. Soc. Proc., 1909, 25, 226.

The author finds that dried precipitated bismuth sulphide dissolves in solutions of both sodium and potassium sulphides, and that the solubility increases rapidly with the concentration of the alkali sulphide. The solubility in potassium sulphide is rather greater than in sodium sulphide of the same concentration. The addition of alkali hydroxides to the alkali sulphide solutions greatly increases the solubility of bismuth sulphide. In a solution of sodium disulphide the solubility of bismuth sulphide is about one-third of that in the corresponding strength of the monosulphide, whilst in solutions of ammonium sulphide and of alkali hydrosulphides and hydroxides, bismuth sulphide is insoluble. From these facts it is shown that the solubility of bismuth sulphide in alkali sulphide solutions must depend on the formation of a complex anion with the sulphur ion of these solutions. Bismuth trioxide dissolves to a slight extent in alkali hydroxides, the solubility being approximately proportional to the concentration of the alkali hydroxide. Towards strong bases it therefore behaves as the anhydride of a weak acid, but to a much less extent than the corresponding oxides of arsenic and antimony.

Carbon; Ordinary —. H. Le Chatelier and Wologdine. Comptes rend., 1909, 148, 1715—1718.

It is generally believed that there exist several distinct modifications of amorphous carbon having different specific gravities and heats of combustion. Of these different varieties, however, the authors have found that acetylene black and retort carbon contain notable quantities of graphite. This finely-divided graphite yields on oxida-

tion graphitic oxide, which settles only with extreme slowness and thus may escape recognition; it can be identified by the production of a voluminous mass of pyrographitic oxide on deflagration. Lampblack, sugar charcoal, wood charcoal, and carbon filaments of electric incandescence lamps were found to be free from graphite. Specimens of these four kinds of carbon when purified by treatment with chlorine at red heat, and then freed as far as possible from gases by compression and the action of a vacuum, were found to have specific gravities ranging from 1.7 to 1.8. The authors consider that in all probability only one variety of amorphous carbon, of sp. gr. about 1.8, exists, the lower values being due to inclusions of gas. Acetylene black and retort carbon, which as stated above, contain graphite, had specific gravities of 2.05 and 1.99 after similar treatment; moreover the residue left after partial combustion of acetylene black had the sp. gr. 2.15.—A. S.

Oxyhydrogen gas; Catalysis of — by means of colloidal palladium. C. Paal and W. Hartmann. J. prakt. Chem., 1909, 80, 337—348.

EXPERIMENTS on the catalytic behaviour of solutions of colloidal palladium (this J., 1904, 208) towards mixtures of hydrogen and oxygen show that the presence of even a slight excess of hydrogen greatly accelerates the formation of water, a maximum being reached when 3.64—12.76 volumes of hydrogen are present to 1 volume of oxygen; a large excess of oxygen causes a marked reduction in the speed of catalysis. Palladium thus behaves quite differently from platinum which produces its maximum effect with normal oxyhydrogen gas.—F. SODX.

PATENTS.

Sulphuric acid; Apparatus for the manufacture of dilute — [by a contact process]. A. M. G. Sebillot and L. Maulefibre, Paris. Eng. Pat. 2192, Jan. 29, 1909. Under Int. Conv., Jan. 29, 1908.

THE process is essentially the same as that described in Fr. Pat. 386,672 (see this J., 1908, 696). The apparatus comprises a chamber provided with superposed perforated shelves, each covered with asbestos cloth supporting the finely-divided catalytic material. The gases from the roasting furnace are mixed with air and steam and led into the top of this chamber, leaving through a pipe at the bottom, which is provided with a cock for running off any condensed sulphuric acid. The gases from the chamber pass through a lead worm immersed in cold water, then through a sheet iron chamber, lined with lead, and containing catalytic material which is sprinkled with water, and finally to the intake of a fan, which produces the necessary draught through the apparatus.—A. S.

Sulphur trioxide; Process and apparatus for making —. G. Eschellmann and A. Harmuth, St. Petersburg. Assignors to General Chemical Co., New York. U.S. Pats. 937,147 and 937,148, Oct. 19, 1909.

(1). THE claim is for filtering lubricating oil from the gases used in making sulphur trioxide by the contact process, in their transit from a gas-pump to the contact chamber. (2). The apparatus comprises an oil-lubricated gas-pump, a contact chamber, and a filter for removing oil from the gases in transit from the pump to the contact chamber.—O. R.

Concentration of acids; Process and apparatus for the continuous —, the extraction of nitric acid by distillation from mixtures containing sulphuric acid, &c. Aktiebolaget Swedish Nitric Syndicate. Fr. Pat. 402,078, April 15, 1909. Under Int. Conv., May 6, 1908.

FOR the continuous concentration of sulphuric or other acid or the separation of nitric acid by distillation from admixed sulphuric acid, the acid is allowed to flow down a vertical column filled with refractory material, which is heated externally by being enclosed in a furnace shaft, and at the same time a current of hot air or other suitable gas is made to pass upwards through the column. The air may be heated by passing down through a pipe in the same shaft, or, the column may be furnished with openings in its lower part, through which the heated gases from the shaft may be drawn or forced. A very slight current of gas is found sufficient to greatly increase the efficiency of the column.—F. SODX.

Nitric acid; Process and apparatus for the concentration of —. Aktiebolaget Swedish Nitric Syndicate. Fr. Pat. 402,079, April 15, 1909. Under Int. Conv., May 6, 1908.

THE process is for the concentration of dilute nitric acid and especially of the weak acid obtained by the oxidation of atmospheric nitrogen. The concentration is effected in two steps, being first carried to about 60 per cent. by direct contact with hot gases, such as those coming from the electric furnaces, and then to 90—97 per cent. by mixing with strong sulphuric acid and distilling off the nitric acid, preferably using the apparatus described in the preceding abstract. The waste heat from the furnace gases is utilised in three stages in the following order:—(1), in heating apparatus for the continuous concentration of the diluted sulphuric acid, resulting from the above process for concentrating nitric acid, in order to bring it up to its original strength again; (2), in heating the column in which the nitric and sulphuric acids are separated; and (3), in concentrating the weak nitric acid up to 60 per cent., preferably by direct contact with the hot gases in a series of four absorption towers. The necessary cooling of the gases from the electric furnaces is thus effected, and a large proportion of the acid produced may be concentrated to 95—97 per cent. strength.—F. SODX.

Alkali carbonates; Manufacture of —. L. Rivière. Third Addition, dated April 9, 1909, to Fr. Pat. 396,448, Nov. 16, 1908 (this J., 1909, 599, 707, 937).

THE alkali fluoride is obtained by decomposing the fluosilicate in an electric furnace or by electrolysis, instead of as previously described. It is then converted into carbonate, as before, by interaction with calcium carbonate; but, as not more than 70 per cent. of the fluoride is thus decomposed, an additional treatment with an alkaline-earth aluminate is proposed; this decomposes the remainder, giving a soluble alkali aluminate, which may be decomposed in solution by carbon dioxide, to give the alkali carbonate and a precipitate of aluminium hydroxide.—F. SODX.

Brine; Treatment of —. G. W. Malcolm, Davenham, and F. T. Minton, Winsford, Cheshire. Eng. Pat. 19,302, Sept. 14, 1908.

A PORTION of the raw brine is electrolysed, and the resulting alkaline solution is mixed with the main bulk of the raw brine, whereby the magnesia and part of the lime present are precipitated. The mixture is filtered, and the clear liquor is then mixed with a further quantity of the electrolysed brine, and carbonated by means of flue gases, to precipitate the remainder of the lime as calcium carbonate. The flue gases are derived from steam generators, which operate non-condensing engines, by which the dynamos producing the electric current are driven, the exhaust steam being used to heat the vacuum pans, in which the purified brine is evaporated. The chlorine evolved in the electrolysis is collected and used for the manufacture of bleaching powder.—O. R.

Potassium salts; Process for the removal of magnesium chloride from solutions of crude —. Consolidierte Alkali-Werke, Act.-Ges. Ger. Pat. 214,948, Jan. 3, 1908.

THE solution of the crude potassium salts is treated with carnallite, whereby potassium chloride is precipitated, the liquor being warmed to prevent lowering of temperature during this operation. The mother liquor from the potassium chloride is then concentrated either in a vacuum apparatus or in an apparatus in which evaporation is effected by a current of air, so that the heat of the liquor is utilised. Carnallite separates from the concentrated liquor, and is used over again, whilst the final liquor is very rich in magnesium chloride.—A. S.

Silica; Manufacture of gelatinous —. A. Poulson, Farnworth, Lancs. Eng. Pat. 491, Jan. 8, 1909.

SODIUM silicate solution of about 25 Tw. is mixed with dilute hydrochloric acid of about 15° Tw. The separation of gelatinous silica is complete in 21 to 36 hours, after which it is washed free from sodium chloride and other soluble matter.—O. R.

Aluminium nitride; Production of —. O. Serpek, Niedermorschweiler, Germany. Eng. Pat. 15,996, July 8, 1909. Under Int. Conv., Sept. 22, 1908.

ALUMINA and carbon in the presence of iron are heated in a current of nitrogen in an electric furnace. The aluminium carbide first formed reacts with excess of alumina to form metallic aluminium, which at once combines with nitrogen to form aluminium nitride. To carry out the process continuously, a bath of iron carbide is kept in circulation by means of a stream of producer gas, which is supplied through an apparatus acting like a circulating injector. A mixture of alumina and carbon is supplied at one end of the furnace and molten aluminium nitride is drawn off at the other. The escaping carbon monoxide is collected and used to pre-heat the raw materials.—O. R.

Precipitated barium sulphate and carbonate; Manufacture of — [from barytes]. C. E. Maistre. First Addition, dated April 26, 1909, to Fr. Pat. 383,758, Nov. 8, 1907 (this J., 1908, 405).

THE crude barium sulphide, obtained by the process previously claimed, is lixiviated with a solution of ammonium chloride, so as to form barium chloride and ammonium sulphide, which are separated by distillation. The ammonium sulphide may then be decomposed by carbon dioxide; this causes a deposition of sulphur and the formation of ammonium bicarbonate, which may be made to react with sodium chloride, so that the ammonium chloride is recovered and sodium bicarbonate obtained, the latter being converted into the normal carbonate and carbon dioxide by calcination. The barium chloride may either be crystallised, or the solution, containing more or less ammonia, may be treated with carbon dioxide, in order to transform it into barium carbonate. The precipitated sulphur may be converted into sulphuric acid for the production of precipitated barium sulphate.—F. SODX.

Hydrogen peroxide; Manufacture of stable, solid mixtures yielding — on treatment with water. Chem. Werke vorm. H. Byk. Fr. Pat. 401,911, April 9, 1909. Under Int. Conv., April 14, 1908.

A PERBORATE, totally or partially dehydrated, is mixed with the equivalent amount of a dry, solid, organic or inorganic acid, or of a solid acid salt, to form a mixture, which yields hydrogen peroxide as soon as it is brought into contact with water.—O. R.

Compounds containing oxygen and nitrogen [nitrates and nitrites]; Production of — by electrical means. P. Bunet and A. Badin. Fr. Pat. 402,012, Aug. 17, 1908.

THE object of the invention is to effect an improvement in the yield of oxides of nitrogen obtained by means of the electric arc; this is done by maintaining the temperature of the arc practically constant during its existence, and by suddenly cooling the products by contact with

a liquid, such as water or alkali, capable of absorbing the oxides of nitrogen. The constant temperature is attained by using an alternating current of fairly high frequency (200—1000 periods per sec.), as directly obtainable with an ordinary generator. The electrodes are arranged to form an upright fork contained in a closely fitting chamber of refractory material, through which a regulated supply of air may be passed from below and which opens above into a larger chamber; a succession of expanding arcs travels up between the electrodes, and each is immediately extinguished at the entrance to the upper chamber by jets of the pulverised absorbing liquid, which absorbs the oxides of nitrogen in the state of oxidation in which they exist at the instant of extinguishing the arc; all dilution of the treated air is thus avoided.—F. SODX.

Ammonium sulphate; Apparatus for granulating, drying, and screening —. Soc. du Gaz de Paris. Fr. Pat. 402,161, Aug. 21, 1908.

THE wet salt is fed through a hopper containing a distributing appliance, to the bottom of a chain elevator, which conveys it into a granulating apparatus. This consists of a series of parallel plates, milled at their edges and mounted on a common vertical axle, about which they rotate horizontally between baille-knives, which are fixed to the casing of the apparatus. Passing from the granulating apparatus, the material falls into a drying chamber, which consists of a long horizontal cylinder fitted with a screw conveyor. Hot gases pass from a furnace through the cylinder in the opposite direction to that of the material. Near the extremity of the drying chamber, the dry salt falls through a screen into a delivering hopper, any material which is too coarse to pass through the screen, being propelled by the conveyor against a grooved plate, which forms the end wall of the drying chamber. The material thus lodged between the end of the conveyor and the grooved plate, is thereby subjected to a process of trituration, which enables it to pass through the screen.—O. R.

Gas-pump [especially for the compression of sulphur dioxide]. J. Carrier. Fr. Pat. 402,810, May 6, 1909.

A CAST iron piston works vertically inside a cast iron cylinder, which forms the body of the pump. The latter is fitted with upper and lower inlet valves on the left side, and with upper and lower outlet valves on the right side. Each valve consists of a circular rubber disc attached to an iron washer of slightly smaller diameter, the rubber disc fitting tightly in the mouth of a tube, which communicates with the pump, and the outer portion of the disc, between the end of the iron washer and the tube, having free play inwards, for aspiration, and outwards for delivery. This is ensured by fixing the rubber discs inside with the iron washers outside, in the case of the inlet valves, and in the reverse order in the case of the outlet valves. The inlet valves communicate by means of suitable tubes with the source of the gas to be compressed, and the outlet valves, by way of a common collecting tube, with the receptacle for the compressed gas. When the piston descends, gas is aspirated through the top left-hand valve and delivered through the bottom right-hand valve, the bottom left-hand valve and the top right-hand valve being at the same time closed by the pressures produced in the cylinder. When the piston ascends, gas is aspirated through the bottom left-hand valve and delivered through the top right-hand valve, the top left-hand valve and the bottom right-hand valve being in this case closed by the pressures produced.—O. R.

Reactions between gases or mixtures of gases; Process for preventing decomposition of the reaction-products in chemical —. A. Scherbius. Ger. Pat. 213,709, Feb. 21, 1906.

IN gas reactions which take place at high temperatures, where it is necessary to rapidly cool the reaction-products to a point at which the reverse reaction cannot take place, it is proposed to effect this cooling by allowing the heated and compressed gases to flow out through a relatively long nozzle, the diameter of which gradually increases, into a chamber in which a lower pressure prevails. The

nozzle itself is preferably cooled. Claim is alternatively made for cooling the gases by utilising their energy to drive a turbine.—A. S.

Oxalic acid together with cryolite; Process for the preparation of —. G. Muth. Ger. Pat. 214,010, June 21, 1908.

A SOLUTION of alkali oxalate in aluminium sulphate solution or a mixture of alkali sulphate, aluminium hydroxide, and water is treated with hydrofluoric acid, either gaseous or in solution, in order to obtain a solution of oxalic acid and a precipitate of artificial cryolite (aluminium-sodium fluoride).—A. S.

Formaldehyde sulphonylates; Process for the preparation of — from nitrogen-derivatives of methylenesulphonylates. Chem. Fabr. von Heyden Akt.-Ges. Ger. Pat. 214,043, July 12, 1908.

THE claim is for the preparation of formaldehydesulphonylates by the action of formaldehyde on the nitrogenous derivatives of methylenesulphonylates obtained by the action of ammonia or amines on formaldehydesulphonylates or by the reduction of the products obtained by the action of ammonia or amines on formaldehydesulphites. For example, the reaction product from aminomethylene-sulphurous acid or its salts and zinc dust (alone or in presence of acids) is digested, in the form of the zinc salt, with formaldehyde and freshly-precipitated zinc hydroxide in order to obtain the slightly soluble, basic, formaldehyde-zinc sulphonylate.—A. S.

Charcoal with great absorptive power; Process for the preparation of — from finely-divided, earthy lignites. R. Goldstein. Ger. Pat. 213,828, March 26, 1907.

EARTHY lignites, unsuitable for distillation, are intimately mixed with a mixture of kaolin and water, and the mass is carbonised in a closed furnace at not too high a temperature. For many purposes the product is said to possess a greater decolorising and deodorising power than animal charcoal and similar substances.—A. S.

Sulphuric acid; Process for the manufacture, concentration, and simultaneous purification of —. G. C. de Briailles, Paris. Eng. Pat. 22,434, Oct. 22, 1908.

SEE Addition of Oct. 19, 1908, to Fr. Pat. 393,665 of 1907; this J., 1909, 473.—T. F. B.

VIII.—GLASS, POTTERY, AND ENAMELS.

Silvering of mirrors; Protection for the —. A. Perot. Comptes rend., 1909, 149, 725.

THE mirror, freshly polished and freed from dust, has poured over its surface a dilute solution of celluloid in amyl acetate, which is then drained off as far as possible. The adhering solution, on evaporation of the solvent, leaves an extremely thin and uniform coating of celluloid on the silver, insufficient to interfere with the clearness or brightness of the image, but enough to protect the metallic surface. The coating is not very hard, and must therefore be protected from mechanical damage; dust must be removed from it by a very light feather brush.—J. T. D.

Ceramic colours; Production of —. A. Heubach. Trans. Amer. Ceram. Soc., 1909, 11, 48—59.

THE different kinds of colours used in the ceramic industry are classified, according to the temperature at which they are fired, as enamel colours, coloured glazes, underglaze colours for low and higher temperatures, and colours for sharp fire. For red enamel colours, ferric oxide and gold are used, the iron giving tints from light orange red to deep cherry-red by choosing a suitable temperature; the flux $1.0\text{PbO}, 0.5\text{SiO}_2, 0.5\text{B}_2\text{O}_3$ is recommended. Red-brown to light brown enamels are obtained from chromium-iron, iron-alumina, and iron-zinc colours. A coral-red can be produced with 28 parts of lead chromate and 75 of a flux made from 85 parts of minium and 15 of flint. To produce purple, carmine, and pink enamels, gold is used. Gold-purple is probably a mixture of colloidal gold and colloidal stannic acid in different proportions. Stannic ammonium chloride (pink salt) is added to dilute gold chloride solution to obtain a purple,

and this may be rendered deeper in colour by adding stannous chloride. Ammonia alum may be substituted for stannic ammonium chloride. For these colours, a flux composed of $0.65\text{—}0.8\text{ PbO}, 0.2\text{—}0.25\text{ Na}_2\text{O}, 0.0\text{—}0.12\text{K}_2\text{O}, 0.5\text{—}1.0\text{ SiO}_2, 0.4\text{—}0.5\text{ B}_2\text{O}_3$, is used. It is necessary to add a small percentage of silver carbonate or chloride to prevent the colours turning violet. All these colours must be fired in an oxidising atmosphere and at a temperature about 800°C . For higher fire, chromium-tin stains are used, either in the glaze or as underglaze. For the production of red glazes the composition of the stains is not so essential as that of the glazes. The author is unable to recommend a good glaze formula, but it should contain much lead and little or no boric acid. If the stains are to be used as underglaze, they should be mixed with kaolin or the body-mixture or glaze to make them adhere to the body and unite with the glaze. The stains themselves are of the following compositions:—Dark red, $0.0047\text{ K}_2\text{O}, 0.9768\text{ CaO}, 0.0181\text{ PbO}, 0.011\text{Cr}_2\text{O}_3, 1.11\text{ SiO}_2, 1.12\text{ SnO}_2, 0.005\text{ B}_2\text{O}_3$; pink, $0.013\text{ K}_2\text{O}, 0.987\text{ CaO}, 0.013\text{ Cr}_2\text{O}_3, 2.26\text{ SiO}_2, 1.31\text{ SnO}_2$; lilac, $0.45\text{K}_2\text{O}, 0.55\text{ Na}_2\text{O}, 0.45\text{ Cr}_2\text{O}_3, 14.28\text{ SnO}_2, 1.10\text{ B}_2\text{O}_3$. Red copper glazes (*rouge flamé*, etc.) develop best between cones 4 and 7. They must be fired in a reducing atmosphere, but if reduced too much they turn brown. Dark colours result from a small content of copper, 0.10 per cent., while an increasing amount of copper gives lighter tints. Seger's copper-red glazes contain barium oxide, but the author recommends the following:— $0.30\text{ CaO}, 0.07\text{ MgO}, 0.16\text{ K}_2\text{O}, 0.29\text{ PbO}, 0.12\text{ Na}_2\text{O}, 0.06\text{ CaO}, 0.20\text{ Al}_2\text{O}_3, 1.06\text{ SiO}_2, 0.11\text{ B}_2\text{O}_3, 0.07\text{ SnO}_2$, for a bluish red; $0.25\text{ CaO}, 0.05\text{ MgO}, 0.14\text{ K}_2\text{O}, 0.32\text{ PbO}, 0.12\text{ Na}_2\text{O}, 0.05\text{ ZnO}, 0.07\text{ CuO}, 0.18\text{ Al}_2\text{O}_3, 2.40\text{ SiO}_2, 0.12\text{ B}_2\text{O}_3, 0.05\text{ SnO}_2$, for a blood red; $0.31\text{ CaO}, 0.02\text{ MgO}, 0.10\text{ K}_2\text{O}, 0.22\text{ PbO}, 0.11\text{ Na}_2\text{O}, 0.13\text{ ZnO}, 0.09\text{ CuO}, 0.26\text{ Al}_2\text{O}_3, 1.75\text{ SiO}_2, 0.22\text{ B}_2\text{O}_3, 0.09\text{ SnO}_2$, for a light red. *Rouge-flamé* may also be produced by reducing the surface only of the glaze. For colours fired higher than cone 9, red can only be produced by gold and chromium-aluminium colours, either as underglaze or in the body. The gold chloride may be dissolved in glycerin, or its aqueous solution be added to a slip and the gold precipitated by sodium hydroxide and glycerin or grape sugar, or stannous chloride. All chromium-aluminium stains should be fired higher than the ware on which they are to be applied. As a colouring ingredient for biscuit ware, the formula $1.0\text{ K}_2\text{O}, 16.53\text{ Al}_2\text{O}_3, 1.00\text{ Cr}_2\text{O}_3, 3.27\text{ B}_2\text{O}_3$, gives a violet-red, fired at cone 14. A salmon colour, used under the glaze, is given by $0.046\text{ K}_2\text{O}, 0.658\text{ MgO}, 0.296\text{ ZnO}, 0.722\text{ Al}_2\text{O}_3, 0.046\text{ Cr}_2\text{O}_3, 0.08\text{ B}_2\text{O}_3$.—H. H. S.

Sheet iron enamels; Coefficient of expansion of —. M. Mayer and B. Havas. Sprechsaal, 1909, 42, 497—499.

THE authors' determinations were made by the Fness method (Poggendorf's Annalen, 180, 497) with rods about 100 mm. long and 7 mm. thick, with pointed ends. The enamel specimens were prepared by drawing from the fused mass, and after cooling in the air, were cut to length, and the ends ground. The results obtained with different enamels are shown in the following table:—

	Ground enamels.			Cover enamels.		Colourless glaze.
	I.	II.	III.	I.	II.	
Silica	51.00	64.86	54.69	55.91	51.00	53.10
Boric anhydride ..	15.79	9.46	12.47	6.93	6.80	14.35
Aluminium fluoride ..	—	—	—	3.95	6.92	—
Sodium fluoride ..	—	—	—	6.03	9.62	—
Calcium fluoride ..	—	3.67	1.68	1.73	—	4.58
Cobalt oxide	0.25	0.21	0.31	—	—	—
Manganese oxide ..	6.71	0.51	0.45	—	—	—
Alumina	7.86	6.45	8.83	10.30	8.85	7.01
Lime	1.51	1.01	1.26	0.54	1.77	1.21
Potassium oxide ..	2.60	1.71	2.54	1.73	2.22	2.49
Sodium oxide	14.84	12.12	14.77	12.85	13.39	17.29
Coefficient of cubical expansion $\times 10^7$..	288.0	245.1	289.2	326.7	348.0	308.6

Six specimens of stamped sheet iron had coefficients of cubical expansion ranging from 384.6×10^{-7} to 418.5×10^{-7} , and a specimen of rolled sheet iron had the coefficient 420×10^{-7} . The results obtained show that the generally accepted view that the function of the ground enamel is to equalise the differences between the expansions of the sheet iron and of the cover enamel is untenable. Actually the ground enamel has a lower coefficient of expansion than the cover enamel, that of the latter being 25–28 per cent. less than that of the iron. An iron rod having a coefficient of expansion of 405×10^{-7} was coated with a ground enamel having a coefficient of 289.2×10^{-7} ; the coefficient of the enamelled rod was 402.9×10^{-7} ; hence the ground enamel must possess great elasticity. The same enamelled rod when coated with a cover enamel having a coefficient of 300.3×10^{-7} , had a coefficient of expansion of 363.9×10^{-7} , that is the expansion was reduced by about 10 per cent. The above results show that the enamel is under great tension, and this may explain the spontaneous formation of cracks in enamelled ware. The aim in practice should be to prepare cover enamels of good covering power, so that only a thin coating is required.—A. S.

PATENTS.

Glass; Electric furnace for the continuous manufacture of —. M. Sauvageon. First Addition, dated Feb. 6, 1909, to Fr. Pat. 401,744, Aug. 7, 1908 (this J., 1909, 1130).

THE improvements permit the employment of a current of low tension, so that no danger may accrue to the glass-blower. The furnace now consists of a tank separated into two parts by a float of refractory material. The part receiving the material to be melted contains the electrodes, mounted so that the current travels transversely through the bath. The part where the glass is collected receives additional heat from gas flames or arcs or an electric resistance. The furnace may also be made with a melting-tank in the middle, and a working-tank on each side.—H. H. S.

Silica ware; Preparation of acid-resisting and refractory —. I. Schlossberg. Fr. Pat. 402,428, April 26, 1909. Under Int. Conv., April 27, 1908.

THE process depends on the reaction represented by the equation: $\text{Na}_2\text{Si}_2\text{O}_7 + \text{H}_2\text{SiF}_6 = \text{Na}_2\text{SiF}_6 + 4\text{SiO}_2 + \text{H}_2\text{O}$. The alkali silicate is made into a vessel of the desired form, and this is then treated with hydrofluosilicic acid and heated to redness. According to the temperature, sodium silicofluoride, or sodium fluoride and silicon tetrachloride, distil over and are condensed, while the vessel remains, composed of pure silica.—H. H. S.

Mineral teeth; Mixture for the burning of artificial —. H. Wienand. Ger. Pat. 214,282, April 9, 1908.

THE mixture claimed consists of kaolin, kieselguhr, and quartz sand with granulated particles of refractory metals, such as nickel or nickel alloys, saturated with carbon. The artificial teeth, e.g., of porcelain, are placed on this mixture and the burning carried out in the usual manner. It is stated that owing to absorption of carbon from the nickel or nickel alloy, the metal fittings of the teeth remain soft and unoxidised, and owing to the slow rate of cooling of the mixture, the production of cracks in the teeth is prevented.—A. S.

Acid- and fire-proof bodies consisting of pure silicic anhydride; Process for the manufacture of —. I. Schlossberg, Charlottenburg, Germany. Eng. Pat. 9394, April 20, 1909.

SEE Fr. Pat. 402,428 of 1909; preceding.—T. F. B.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

PATENTS.

Stone; Fire-proof — and process of manufacturing same. S. W. Berglund, Stockholm. Eng. Pat. 6299, March 16, 1909.

SEE Fr. Pat. 399,384 of 1909; this J., 1909, 984. From 2 to 20 per cent. of graphite is added to the mixture of quartz and lime.—T. F. B.

Aluminous materials; Method of treating —. A. C. Higgins, Worcester, Mass. U.S. Pat. 930,376, Aug. 10, 1909.

ABRASIVE materials made by fusing alumina in the electric furnace often contain iron, titanium and silicon, either as elements, alloys, carbides or oxides. As these are often irregularly disseminated, and are subject to oxidation and other changes, they give rise to objectionable local modifications of structure. The fused product is accordingly broken up into suitable sizes and roasted in an oxidising atmosphere. It may then be sold for making abrasive papers and the like, or it may be ground, washed with acid or alkaline solutions, moulded with clay and feldspar into vessels, and fired in the usual way.—H. H. S.

Wood; Process of staining, impregnating, or preserving — by chemical reaction. A. Jalm and M. Grünhut. Fr. Pat. 402,527, April 29, 1909.

SUBSTANCES that have been introduced into wood as solutions for staining or preserving are usually washed out in the course of time by the action of water. To overcome this, the wood, after being steamed to decompose albumin, is treated successively with the solutions or vapours that will form the desired stain or preservative by chemical action. For example, if it be desired to stain wood yellow, a solution of cadmium chloride is first forced into the wood, and then a solution of sodium sulphide follows. Insoluble cadmium sulphide is formed in the wood, while sodium chloride is washed out.—H. H. S.

Refractory basic stones of low heat conductivity; Process for the manufacture of —. J. Carstens and P. Kretzmann. Ger. Pat. 214,234, Feb. 5, 1909.

HIGHLY basic materials such as cement or slag are fused and used as binding material for the production of stones from basic granular materials such as cement clinker or lime. Stones thus produced are stated to possess good strength and low heat conductivity.—A. S.

Cements, cires, and similar materials; Process for treating — in a rotary kiln. G. Polysius. First Addition, dated April 15, 1909, to Fr. Pat. 390,316, May 16, 1908 (this J., 1908, 1021).

THE improvement consists in feeding the fuel into the kiln under pressure, which enables the feeding tube to be much shortened and causes the zone of greatest heat to be displaced into the interior of the cylinder to such an extent that the whole capacity of the cylinder may be utilised, and all the cooling effected in the one cylinder.—H. H. S.

Wood preserving; Process for obtaining solutions of metallic salts free from acid for —. B. Diamand, Idaweiche, Germany. Eng. Pat. 23,990, Nov. 9, 1908.

X.—METALS AND METALLURGY.

Blast-furnaces; Limit of fuel economy in iron —. X. M. Langdon. Trans. Amer. Inst. Min. Eng., 1909, 919—940.

IN order to ascertain whether additional large fuel economies in iron blast-furnace practice are likely to be effected in the future, the author compares the theoretical fuel requirements for each detail of the smelting, with data from actual and hypothetical furnace practice. He tabulates the direct heat requirements under ten heads, *viz.*, reduction of iron, reduction of silicon, expulsion of moisture, of carbon dioxide, and of volatile substances in the fuel, expulsion of volatile substances in the ore and of combined water, fusion of the iron, fusion of the slag, and decomposition of the moisture in the blast. The heat carried off in the flue gases, and in the flue dust, and that lost by radiation is classed under indirect utilisation of heat. The heat supplied comprises, in the zone of fusion, the heat carried in by the blast and that of carbon burning to carbon monoxide at the tuyères; in the zone of reduction, carbon burning to carbon monoxide and carbon monoxide burning to carbon dioxide. Tables are given showing, in B.T.U., the total heat required theoretically, and the heat supplied, in the case of 27 furnace runs, together with details of the charges and products. The figures show that although improvements may still be effected in the direction of fuel economy by the elimination of moisture and volatile matter, yet there is no room for such striking reductions as resulted from the use of the dry blast.

—F. R.

Iron for electrical work; Effect of manganese on —. C. F. Burgess and J. Aston. Electrochem. and Met. Ind., 1909, 7, 476—478. (See also this J., 1909, 1134, 1135.)

THE magnetic permeability, coercive force, and retentivity of different alloys of pure iron and manganese were investigated. A series of 10 alloys containing from 0.5 to 10.42 per cent. of manganese were made by heating the metals in a magnesia-lined graphite crucible in an electric resistance furnace. Unannealed forged bars showed a successive deterioration in permeability, with increased manganese content, until at 10.42 per cent. the bar was non-magnetic. Annealing at 675° C. increased the permeability in all the alloys, but a second annealing at 1000° C. practically reduced the permeability to that of the raw forged bars. Three of the bars were subsequently quenched at 900° C. with similar results to those obtained by annealing at 675° C. The values for retentivity and coercive force decreased and increased respectively with successively larger amounts of manganese, and both closely followed the fluctuation of the permeability when the alloys were subjected to similar thermal treatment. A series of tables and curves is given.—F. R.

Iron; Phosphides of —. H. Le Chatelier and S. Wologdine. Comptes rend., 1909, 149, 709—714.

IN chemical literature 9 phosphides of iron are described, having the formulae, Fe_3P , Fe_2P , Fe_3P_2 , Fe_2P_2 , Fe_2P_3 , FeP , Fe_3P_4 , and Fe_2P_5 . Of these, five are certainly mixtures, and the other four are definite compounds, though the separate existence even of two of these (FeP and Fe_2P_3) is hardly established so certainly as that of the other two (Fe_3P and Fe_2P), the evidence for which is based on:—(a), The constancy of their composition when prepared by different methods; (b), the existence of characteristic points of magnetic transformation; (c), the existence of maxima in the fusion curve of phosphorus-iron mixtures at points corresponding with their composition; (d), their behaviour in regard to solubility in dilute or concentrated acids. The modes of preparation and chief characters of these

four phosphides are summarised below:— Fe_3P .—By treating phosphoric pig irons with weak acids (Stead); by fusing 9 parts of reduced iron with 1 part of phosphorus, powdering the mass after reaction, and separating the most strongly magnetic portions, which consist of Fe_3P ; by fusing copper phosphide with enough iron to remove the phosphorus completely, pulverising the upper layer after cooling, and removing from it any non-magnetic portions. Specific gravity, 6.74. Temperature of magnetic transformation, 445°—435° C. Magnetic permeability about one-third that of iron. Melting-point, 1110° C. Insoluble in dilute hydrochloric acid, but soluble in the concentrated acid, with evolution, not of phosphine, but of pure hydrogen—

It is not yet certain whether or not this compound, with that next described, can form a solid solution. Fe_2P .—By fusing cupric phosphide with a quantity of iron insufficient to remove all the phosphorus, and treating the ingot with nitric acid, when crystalline needles of Fe_2P are left undissolved; by fusing reduced iron with phosphorus, as above—the non-magnetic portion consists of this substance; by reducing ferric phosphate by the "thermite" method. Specific gravity, 6.56. Temperature of magnetic transformation, 80° C. Permeability about one-fiftieth of that of Fe_3P . Melting-point, 1290° C. Is not attacked even by hot concentrated acids, save boiling *aqua regia*, which dissolves it. FeP .—By passing phosphorus vapour at a red-heat over Fe_2P , pulverising the product, and repeating the treatment with phosphorus vapour as long as increase of weight occurs. Sp. gr. 5.76. Temperature of magnetic transformation, 48° C. Permeability $1\frac{1}{2}$ times that of Fe_2P . Fe_3P_2 .—By passing hydrogen containing the vapour of phosphorus di-iodide over iron reduced from the oxalate. On the edges of the boat are found steel-grey crystals of sp. gr. 4.5. They are very feebly magnetic, and show no transformation point, but slightly increase in permeability when cooled to —50° C.—J. T. D.

Cyanide treatment of silver minerals. T. P. Holt. J. Ind. and Eng. Chem., 1909, 1, 694—698.

THE author's experiments were made mostly with chemical compounds and with artificial ores of known mineralogical composition. The detailed results are given in the form of curve-diagrams, but the following conclusions are drawn:—The halogen compounds of silver are the most soluble in cyanide solution and dissolve without the aid of oxygen. In an aerated cyanide solution, native silver is next in order of solubility. In order to obtain good extractions in the case of silver sulphide (argentite), the presence of oxygen or an oxidising agent is essential, and soluble sulphides must be removed from the solution as they are formed. For this latter purpose, lead acetate is commonly employed, but litharge may be used with advantage, being less expensive and not seriously affecting the extraction when present in slight excess. Mercury compounds when used in this connection are effective by reason of their ability to form insoluble sulphides. The solubility of complex antimony- and arsenic-silver minerals in cyanide solution is diminished by the presence of mercury or lead compounds. Cyanogen bromide alone is not a solvent of silver minerals, but in some cases increases the extraction obtainable with cyanide solution, owing to its oxidising action. As a preliminary to treatment with cyanide solution, a chloridising roast is about equally effective with all silver minerals. Foreign minerals interfere more in the cyaniding of silver ores than in that of gold ores.—A. S.

Manganese silver ores; Cyanide treatment of Mexican —. E. M. Hamilton. J. Chem. Met. and Min. Soc., S. Africa, 1909, 10, 65—67. (See also Linton, this J., 1909, 606.)

THE author describes a long series of tests made on a refractory manganese-silver ore in order to render it amenable to cyaniding. Only with five of the methods were any appreciable extractions with cyanide subsequently obtained, *viz.*, (1), a preliminary chloridising

roast; (2), roasting with sulphur out of contact with air; (3), treatment with alkali sulphides; (4), treatment with hydrochloric acid; (5), treatment with a 5 per cent. solution of sulphurous acid. The preliminary treatment with hydrochloric acid enabled a 94 per cent. extraction to be made in the laboratory, but the high cost prohibited its adoption on a practical scale. An 84 per cent. extraction was obtained by the use of the sulphurous acid solution with the consumption of only four lb. of cyanide per ton, and this method would have been used had the ore been a little richer.—F. R.

Copper-aluminium alloys; Transformation-points of —.
(*Relation of electrical resistance to temperature*).
M. Barrée. *Comptes rend.*, 1909, **149**, 678—681.

FROM the curves representing the variation of the electrical resistance with temperature in the alloys of copper and aluminium, the author draws the following conclusions:—1. The observed transformation-temperatures (about 500° and 750° C.) agree with those recorded by Guillet. There is also shown in the curves a singular point at 200° C., but further observation of other characters is required to show whether this is a transformation-point or not. 2. The variations of resistance are reversible, save near the transformation-temperatures; these points, on the cooling-curve, are lower than on the heating-curve. 3. Successive heatings do not affect the temperatures of transformation, but cause the curves to become better defined, probably through the alloys becoming more nearly homogeneous. 4. The very strong tendency to liquation in these alloys, even in very small ingots, is clearly brought out by these observations.—J. T. D.

Tungsten; A volumetric process for the determination of —.
E. Knecht and E. Hilbert. *Chem. Soc. Proc.*, 1909, **25**, 227.

THE process is based in the first instance on the well-known fact that tungstic acid is reduced by zinc and hydrochloric acid to tungsten dioxide, which, in presence of excess of acid, yields a clear light brown solution. If now a solution of a ferric salt be added, the dioxide is oxidised to the trioxide. The end-point is perceived by the disappearance of the intense blue colour of the intermediate compound corresponding with tungsten pentachloride, the reaction

being quantitative. It is thus possible to determine tungsten volumetrically in presence of iron. Potassium thiocyanate may also serve as indicator, but does not offer any particular advantage.

Vanadium; Colorimetric method for the estimation of small quantities of —.
A. W. Gregory. *Chem. Soc. Proc.*, 1909, **25**, 232.

THE method is based on the colour reaction which takes place when a solution of vanadium in concentrated sulphuric acid is added to a solution of strychnine in the same acid. A violet colour is first formed, and this changes to orange. As the latter colour is quite permanent, and is proportional to the quantity of vanadium present, a comparison of the colour produced with that given by a known amount of vanadium under similar conditions indicates the amount of vanadium present in the solution tested. This test is not given by titanium, tungsten, or molybdenum, nor does their presence in relatively large quantities interfere with the formation of the colour given by vanadium. The presence of iron interferes with the reaction. This element must therefore be removed before the test can be applied.

Mercury, and also mercury and silver; Volumetric determination of —.
E. Rupp and L. Krauss. *Ber.*, 1902, **35**, 2015—2017.

Mercury.—As an example, a solution of 25.3529 grms. of pure mercuric oxide in nitric acid, was made, and this was diluted with water to 1 litre. 10 c.c. of this solution was now diluted with 50 c.c. of water, and 1–2 c.c. of a cold saturated solution of iron alum added, and sufficient nitric acid of about 30 per cent. strength to completely

decolorise it. The resulting solution was then titrated with a $N/10$ potassium thiocyanate solution, in the usual way, so as to leave a faint light brown coloration. In the present case, 23.40–23.45 c.c. were required, corresponding to 99.80–100.03 per cent. of the true amount. Volhard's original method with a neutral solution instead of one containing some excess of nitric acid, is not so accurate. (*Annalen*, 190, 1.) See also Cohn, this J., 1901, 1243.

Mercury and silver.—10 c.c. of the mercuric solution already referred to, and 10 c.c. of $N/10$ silver nitrate solution, were also treated with water, iron alum, and nitric acid as already described, and then in the usual way with $N/10$ thiocyanate solution, until the faint brown tint appeared. Thus, it is clear that since the thiocyanate produces at first no precipitation, that the mercury is converted into thiocyanate, which at first dissolves in still unchanged mercuric nitrate solution, whilst the silver is only subsequently precipitated. When the sum of both components (mercury and silver) is ascertained, the silver alone is determined in another portion of 10 c.c. of the mixed solution, by the Gay-Lussac method with $N/10$ sodium chloride solution, the liquid being well shaken before each renewed addition of sodium chloride. Results accurate.

Mercury; The volumetric determination of —, and the determination of silver in presence of mercury.
Joseph Knox. *Chem. Soc. Proc.*, 1909, **25**, 227.

THE thiocyanate method of Rupp and Krauss (see preceding abstract) for the determination of mercury in a solution of mercuric nitrate has been tested, and found to be both rapid and accurate.

The author showed that the estimation of silver by Gay-Lussac's method in presence of mercuric nitrate (by Rupp and Krauss' method) is impracticable, and described a volumetric method which depends on the solubility of silver chloride in potassium cyanide, but the gravimetric estimation of the silver is recommended as being more accurate and convenient. The accuracy of the latter method has been proved in a considerable number of determinations, in which the quantity of mercuric nitrate present was varied greatly.

Vanadium in ores, etc.; Rapid method of determining —.
P. y Alvarez. *Chem.-Zeit.*, 1909, **33**, 1149.

FROM 0.5 to 1 gm. of the finely-ground ore is fused with 7 or 8 times its weight of pure dry sodium peroxide, keeping the mixture at a red heat for about 20 minutes. After extraction of the mass with boiling water, the alkaline filtrate is acidified with sulphuric acid, alcohol added, and without filtering, a current of sulphurous acid is passed through until the solution is nearly saturated. This is necessary to effect complete reduction, especially if arsenic be present. If necessary the blue liquid is filtered, and the alcohol and sulphurous acid removed by heating and passing a current of carbon dioxide through the solution. At this stage if arsenic is present the solution is treated with sulphuretted hydrogen, the arsenic sulphide filtered off, and the excess of sulphuretted hydrogen expelled by boiling. The vanadium solution, which should be of approximately 1 per cent. strength, is titrated with potassium permanganate. As a check, a solution of ammonium metavanadate from which the ammonia has been expelled by caustic soda, is treated under precisely similar conditions with regard to concentration, acidity, and temperature. The oxidation of the hypovanadic acid to vanadic acid is considered complete when the change from the blue to pink colour is permanent.—W. N. B.

Vanadium and other metals; Preparation of — by the thermite method.
W. Prandtl and B. Bleyer. *Z. anorg. Chem.*, 1909, **64**, 217—221.

A MIXTURE of calcium and aluminium, unlike aluminium alone, readily reduces vanadium pentoxide to the metal, and the heat evolved is sufficient to melt the product. The vanadium obtained is not however quite pure, containing not more than 94.5 per cent. (using 100 grms. of fused and powdered vanadium pentoxide, 55 grms.

of calcium, and 24.7 grms. of aluminium); it is crystalline and very hard, being difficult to break with a hammer, and scratches glass, steel, and quartz. Pure vanadium can be obtained in the above process only by using pure calcium and aluminium. As a cheap and efficient substitute for magnesia-lined crucibles, a cylindrical tin canister, lined with finely-ground fluorspar or other suitable material, is recommended, an open cylinder of smaller diameter, such as a lamp chimney, being temporarily introduced during the packing process and withdrawn after the thermite mixture has been filled in. Manganese, chromium, iron, cobalt, and nickel have also been successfully prepared by this method.—F. SODX.

Vanadium; Preparation of — by the aluminothermic method. R. Vogel and G. Tammann. Z. anorg. Chem., 1909, 64, 225.

EXPERIMENTS by the authors show that it is possible to reduce vanadium pentoxide by means of aluminium alone (compare preceding abstract), and metal containing 99.07 per cent. of vanadium has been obtained by the process, but the conditions necessary for success have not been fully ascertained.—F. SODX.

Metals; Emission of gas by heated — G. Belloc. Comptes rend., 1909, 149, 672–673.

STEEL heated *in vacuo* begins to give off gas at 150°–200° C., and the evolution is very noticeable at 400° C. When the evolution at a given temperature ceases, more gas is evolved, not only if the temperature be raised higher, but also if, after an interval of time, the metal be again heated to the original temperature. Thus, 50 grms. of steel wire yielded, on seven successive heatings

to 780° C., at intervals of 3 days, quantities of gas gradually diminishing from 3.30 to 0.20 c.c., and amounting in all to 9.55 c.c.—J. T. D.

Ozone; Action of —, on metals, and the cause of passivity. W. Manchot. Ber., 1909, 42, 3942–3945.

As previously shown (this J., 1907, 825), ozone reacts on silver most readily at a temperature of 240° C., but if the metal be rubbed with various oxides, including silver oxide, ozone acts readily on it at the ordinary temperature. By anodic oxidation in sodium hydroxide or in acid, silver acquires this same property of becoming acted on by ozone at the ordinary temperature; and such an anodic silver plate is found to be electro-positive towards, or "nobler" than, a pure silver plate not reactive to ozone, so that it may be spoken of as "passive" silver. By utilising the action of ozone as a test for the presence of oxide, the author finds that all silver heated in the air to 200° C. or above becomes coated with oxide, though the film so formed may be not only unweighable, but insufficient to affect visibly the polish of the metallic surface.

Other metals behave similarly to silver, in their relations to ozone; and the ozone test lends support to the "oxide film" theory of passivity, for iron and other metals brought into the passive state by immersion in acid or otherwise, all show, when tested with ozone, a film of oxide, though their weight or their appearance may not have been sensibly altered. He suggests that the loss of passivity may be caused by the rupture of continuity between the film and the underlying metal.—J. T. D.

Mineral produce of the United Kingdom and of the Isle of Man. Mines and Quarries Report and Statistics, Part 3. [T.R.]

Description of mineral.	1907.		1908.

§ Information not supplied.

In 1908, 35,233,523 tons of coal were used in the manufacture of coke; 7,323,817 tons of coke were produced at gas works and 11,213,651 tons at coke ovens; a total of 18,537,468 tons, valued at £12,467,287. There were 26,214 coke ovens in use in the United Kingdom in 1908; of these, 19,478 were bee-hive ovens, 2198 were Coppée ovens, 1044 Simon-Carvès, 876 Otto-Hilgenstocks, 760 Semet-Solvays, 378 Koppers, 294 Simplex, and 210 of the Hüssener type. Of the Coppée ovens, 1122 were in operation in Glamorgan and 592 in Monmouth.

PATENTS.

Metal [iron or steel]; Method of hardening and toughening — H. W. Partin, Portsmouth, Va. U.S. Pat. 937,263, Oct. 19, 1909.

"THE heated metal is treated with a mixture of powdered borax and soda, with or without common salt or salt and cobalt," and then tempered. Or, after treating with borax and soda the metal is immersed in an aqueous bath of lime, soda and borax, with or without sal-ammoniac. —F. R.

Steel; Production of — free from protoxides. O. Thullner, Assignor to Firm of Bismarckhütte, Bismarckhütte, Germany. U.S. Pat. 937,486, Oct. 19, 1909.

STEEL is first "blown" and then transferred to a basic electric furnace, where silicon is added. The metal is heated until both the slag and metal are deoxidised, after which a further amount of silicon is added. —F. R.

Steels; Refining of liquid — obtained in furnaces not heated electrically. Soc. Anon. Electrometallurgique (Procédés P. Girod). Fr. Pat. 402,758, May 6, 1909.

THE liquid steel from the Thomas, Bessemer or Martin furnace is run into an electric furnace. It should not be in a peroxidised condition but, on the contrary, should contain a certain quantity of carbon, silicon, manganese and even phosphorus. In order to facilitate the disengagement of the gases retained in the metal, and the separation of the slag, the temperature is allowed to fall to about 700°—900° C., or even lower. It is this cooling, as opposed to the supposed efficacy of raising the temperature to 2000° C., which constitutes the essential feature of the process. Finally, after the cooling, the temperature of the charge is raised, a certain quantity of iron ore or metallic oxide being added in order to facilitate the elimination of residual impurities. —C. A. W.

Spathic iron ores; Method for increasing the reducibility of —. Cöln-Müsoner Bergwerks-Act.-Ver. Fr. Pat. 402,077, April 15, 1909.

CARBONATE ores of iron are crushed and pressed, with or without an agglutinant, into small cakes, which are heated, out of contact with air, until sufficient cohesion is obtained. The masses so produced are firm and porous and do not so readily slip down the furnace out of the zone of reduction. Moreover, by a sufficient admission of air, they may be converted into oxides more readily reducible by the carbon monoxide. In order to apply the process to the poorer spathic ores, it is advisable to enrich the material by eliminating the gangue, if necessary by some method of magnetic separation. By means of the process, cast iron containing large proportions of manganese can be obtained from certain spathic ores, without the addition of other manganiferous ores. —C. A. W.

[Gold-silver] alloys. E. B. Craft and J. W. Harris, Hackensack, N.J., Assignors to Western Electric Co., Chicago, Ill. U.S. Pat. 937,284 and 937,285, Oct. 19, 1909.

A GOLD-SILVER alloy hardened with platinum consists of 67.5 to 70 per cent. of gold, 25 of silver and 5 to 7.5 of platinum. Another alloy consists of the same quantities of gold and silver but with 5 to 7.5 per cent. of nickel in place of the platinum. —F. R.

Gold amalgam; Apparatus for distilling mercury from —. W. E. Bennett, London. U.S. Pat. 937,356, Oct. 19, 1909.

THE amalgam is contained in a tray, supported on a tall iron stand placed in the centre of a water trough. The tray is surrounded by a cylindrical cover opening only below the surface of the water, and an annular fire-basket is arranged round the upper part of the cover. The products of combustion are carried away by means of a hood resting on the fire-basket. —F. R.

Smelting furnaces. Soc. Anon. d'Exploitation des Brevets Cubilot A. Baillot. Eng. Pat. 22,082, Oct. 19, 1908. Under Int. Conv., Jan. 8, 1908.

THE invention consists of a combined smelting furnace and fore-hearth (for cast iron), so arranged that each part is under separate control, the waste heat of the furnace being utilised for heating the air for the blast. The pig-iron flowing from the furnace into the previously heated fore-hearth, is there subjected to the action of the blast, solid fuel being absent, and is thus partially decarburised. (Reference is directed to Eng. Pat. 16 of 1864, 10,206 of 1887, 14,376 of 1899, and 9974 of 1902; this J., 1888, 570; 1903, 568.) —W. E. F. P.

Furnace for the treatment of metals, ores, and alloys. E. T. Fennell, Woolwich, and J. Sackett, Charlton, Kent. Eng. Pat. 22,412, Oct. 22, 1908.

A ROTATING cylindrical ore conveyor lined with refractory material and heated internally by the combustion of

vaporised oil in combination with a hot blast, is placed between an inclined feeding shoot and a regenerative open-hearth furnace of cylindrical shape. A mixture of finely powdered ore, flux and small non-caking fuel, is mechanically fed by means of the inclined shoot into the ore conveyor. The ore is reduced and desulphurised during its passage through the conveyor and eventually falls into the furnace hearth, where a bath of molten iron and slag is maintained.—F. R.

Ore-reducing furnace. G. F. Rendall, Assignor to American Reduction Co., N.J. U.S. Pat. 931,145, Aug. 17, 1909.

THE patent relates to a furnace in which combustible gases generated in retorts first pass through reducing chambers charged with the calcined ore, and are then burned in the furnace proper which is charged with the ore to be calcined. This furnace comprises an inclined chamber, which is charged with ore at its upper end; the calcined ore is discharged at the lower end of this chamber into two reducing chambers arranged one at either side thereof and communicating with it through conduits inclined downwards. The reduced ore is finally discharged through a valved outlet into closed trucks which are provided with valved charging conduits and with couplings for connecting these to the furnace outlets, so that the ore is not exposed to the air. Each reducing chamber is provided with a hinged perforated plate forming a false bottom to support the ore, and the gas from the retorts is admitted beneath these plates. The ore is discharged by lowering these plates so that the front edge comes below the discharge orifice. The retort furnace is arranged in the base of the structure and hot air and combustion products are drawn from the flue of the retort furnace and forced by a blower into the inclined calcining chamber, where they mix with the gas which has passed through the reducing chambers, and ignite it so as to heat the ore. Water-sealed covers are provided so as to prevent damage from any explosion which may occur in the calcining chamber.—A. T. L.

Tin-plate waste; Process for de-tinning —, by means of chlorine. H. von Schütz, Wetzlar, Prussia. Eng. Pat. 23,594, Nov. 4, 1908. Under Int. Conv., Dec. 13, 1907. Addition to Eng. Pat. 22,337 of 1908.

THE process is conducted as described in the main patent (see Fr. Pat. 395,999 of Nov. 6, 1908; this J., 1909, 480), all the operations being performed in the chlorination chamber itself.—W. E. F. P.

Aluminium; Soldering of —. A. Nielsen, Drammen, Norway. Eng. Pat. 15,105, June 28, 1909. Addition to Eng. Pat. 5055 of 1908, dated March 9, 1907.

IN place of electrolytically coating the aluminium object to be soldered, first with nickel and subsequently with tin, as in the main patent (see this J., 1908, 1157), a coating of copper is now substituted for that of tin. The copper electrolyte consists of about a 22 per cent. aqueous solution of copper sulphate, acidified with sulphuric acid. The nickel electrolyte consists of about 4 parts by weight of nickel salts, 2 of "spirits of ammonia," 20 of citric acid, and 100 of water.—F. R.

Sherardizing apparatus. [Coating metals with zinc.] A. F. Schroeder, Cleveland, Ohio. U.S. Pat. 933,725, Sept. 7, 1909.

THE articles to be sherardized are placed, together with the zinc dust, into a series of horizontal cylinders arranged upon a movable carriage which is run on rails into the furnace. The cylinders, which are rotatable about their long axes, have covers extending their entire length. When the operation is finished, the carriage is drawn from the furnace and the covers of the cylinders removed. A large tightly-fitting cover is then placed over the whole carriage and the cylinders rotated, causing their contents to be deposited on to a sieve placed between the rails, the cover preventing the scattering of the zinc dust.—F. R.

Copper; Recovery of the — contained in exhausted cleansing baths. A. Göpfert. Fr. Pat. 402,338, April 22, 1909.

IN order to recover the metal from the exhausted acid solutions which have been employed for cleaning articles of copper or copper alloys, it has been usual to add scrap iron to the concentrated liquid. In practice, however, this reaction is accompanied by an abundant evolution of injurious nitrous fumes and by the production of great heat which may give rise to spontaneous inflammation, in the presence of oily substances. It is therefore proposed to dilute the cupriferous solution with a certain amount of liquid from which the copper has been precipitated. This liquid is contained within earthenware vessels arranged in tiers one above the other, so that the overflow from one passes into the next following. Each receptacle contains a partition reaching about two-thirds of the way down and forming a vertical channel connected with the overflow. The vessels having been filled with scrap iron up to the lower edges of the partitions, and with the liquid free from copper up to the brims, the cupriferous solution is run gradually into the top one, the flow being continued until the purified liquid has been displaced throughout the system. The solution diluted in this way is allowed to remain in contact with the iron for 24 hours, when the whole of the copper will have been precipitated.—C. A. W.

Metals or their alloys; Treatment of —. A. E. Greene. Fr. Pat. 402,353, April 24, 1909. Under Int. Conv., April 26 and July 22, 1908.

IN the application of the method to the elimination of oxidisable elements, as in the refining of steel, the material is maintained in the fused state at a temperature at which the affinity for oxygen of the element or elements to be eliminated, is greater than the affinity for oxygen of those to be retained. Under these conditions the metal is submitted to the action of a gaseous mixture which has an oxidising action towards those elements to be eliminated, but a reducing action towards those to be retained. Preferably, some gas is used in the gaseous mixture, which acts as a reducing agent towards the flux employed as well as towards the oxides of all the metals to be retained. In this way, by the use of a calcareous flux, the diminution of sulphur, phosphorus and analogous impurities is facilitated. Blast-furnace gases, containing both oxides of carbon, at suitable pressures, can be employed, in this way, for the selective elimination of the elements. Thus, in the production of a steel, it is possible to oxidise and remove the carbon, whilst retaining the silicon, or, on the other hand, the whole of the silicon can be removed without eliminating the carbon. The electric furnace employed is provided with an arrangement by which the gases may be mixed before entering the tuyères, and with an aspirator, so that the pressure within the reaction chamber can be exactly regulated. The method is applicable to the production direct from the ore, or from the blast-furnace product, of low-carbon steels containing manganese, titanium, silicon, nickel, cobalt, molybdenum, tungsten, or chromium. As an example, the heated product from a Bessemer converter was maintained in the furnace at a temperature of 1700° C., the flux employed consisting of lime or fluorspar. The composition of the gas passed through the tuyères was: Carbon dioxide, 14 per cent.; carbon monoxide, 21 per cent., the remainder being composed of inert gases. Under these conditions, and without any oxidation of iron, the proportion of phosphorus was reduced from 0.96 to 0.19 per cent., that of sulphur falling from 0.41 to 0.13 per cent.—C. A. W.

Aluminium alloys; Light —. Soc. Anon. Le Ferro-Nickel. Fr. Pat. 402,450, Aug. 29, 1908.

THE claim relates to a class of light alloys of aluminium with copper, manganese, and silver, the proportions of the components varying between the limits: aluminium 94 to 98 per cent., copper 1.50 to 4.00 per cent., manganese 0.25 to 1.25 per cent., silver 0.25 to 1.25 per cent. The mechanical properties, resistance to rupture, limit of elasticity and extension, of two alloys, having the respective compositions, aluminium 96.5 and 95.5 per

cent., copper, silver and manganese 3.5 and 4.5 per cent., are much superior to those of pure aluminium. The alloys are ductile, very malleable, and may be forged and rolled in the hot or cold conditions.—C. A. W.

Sulphide ores; Roasting of ——. Maschinenbau-Anstalt Humboldt. Fr. Pat. 402,737, May 5, 1909. Under Int. Conv., Dec. 21, 1908.

THE claim is for effecting the roasting of sulphide ores under diminished pressure.—C. A. W.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

(A.)—ELECTRO-CHEMISTRY.

Electrode efficiency of furnaces. C. Hering. Electrochem. and Met. Ind., 1909, 7, 473–474.

If the voltage between the inside or hot ends of the two electrodes of an electric furnace be divided by the voltage between the outer or cold ends, a figure is obtained which is called by the author, "electrode efficiency." In addition to the electrical loss, there is also a heat conduction loss, so that there is a certain drop of voltage in the electrodes of an electric furnace at which the total losses are a minimum. This voltage is called by the author "electrode voltage," and is a physical constant. It is independent of the length and cross-section of the electrode and also of the current passing through it. It is, however, dependent on the temperature drop in the electrode and as a constant must be understood to refer to 1 degree temperature drop. For 1 degree of temperature drop,

$$e = A \sqrt{\frac{k}{K}} \text{ or } e = A \sqrt{\frac{r}{K}},$$

where e is the "electrode voltage," k the heat conductivity, K the electrical conductivity, r the electrical resistivity (resistance), and A is a constant depending on the units employed. For carbon, $e = 0.0224$ volt, and for graphite, $e = 0.0231$ volt. The designer of an electric furnace can only reach these minimum losses, and he can only increase the electrode efficiency by increasing the total voltage of which the electrode voltage is a small part.—J. W. H.

Electrolytic determination of cobalt. Bruylants. See XXIII. Inorg. Quant.

Insulating process for electrical machines. A. J. Boulton, London. From Felten und Guillaume-Lahmeyerwerke Act.-Ges., Frankfurt a. M., Germany. Eng. Pat. 19,263, Sept. 14, 1908.

PARTS of electrical machinery to be insulated are coated with a solution which can be converted, by subsequent treatment, into a solid mass. For example, the parts may be covered with a solution of acetylcellulose, or with a solution of rubber, which is subsequently vulcanised. The parts to be insulated may be held apart mechanically during the operation. (Reference is directed to Eng. Pats. 5647 of 1894; 16,248 of 1895; 13,973 of 1900; 2264 of 1902; 18,251 and 26,456 of 1903; 2066 of 1906.)—J. W. H.

Electrical-heating method. W. M. Johnson, Iola, Kans., Assignor to The Continuous Zinc Furnace Co., Hartford, Conn. U.S. Pat. 937,074, Oct. 19, 1909.

LEAKAGE of current, through the walls or lining of an electric furnace, is reduced by feeding, between the charge and the walls of the furnace, a granular material containing the constituents of the charge, but having a high electrical resistance relatively to that of the charge.—B. N.

Silicon carbide [electrically]; Process of producing ——. F. J. Tone, Assignor to The Carborundum Co., Niagara Falls, N.Y. U.S. Pat. 937,119, Oct. 19, 1909.

A CHARGE of silicious and carbonaceous material is supplied to a furnace, and within the charge is maintained an electric arc, of sufficient heating capacity to produce silicon carbide. The arc zone is moved, from the material formed, in the direction of the unreduced mixture, thus allowing a column of silicon carbide to build up under the electrodes. Portions of the silicon carbide are withdrawn from time to time from the end of the column farthest from the arc zone, and fresh material is supplied as required.—B. N.

Exciting liquid, replacing bichromate in batteries of great output. P. M. Séguin. Fr. Pat. 402,161, Aug. 21, 1908.

POTASSIUM or sodium bichromate is replaced by a liquid composed of distilled water, nitric acid, sulphuric acid, lead peroxide, zinc oxide, and sodium chloride in suitable proportions.—B. N.

Furnace; Electric — with superposed recharger. A. Helfenstein. Fr. Pat. 402,652, May 3, 1909.

IN the cover of the furnace, at the side of the recharger, large gas-tight openings are arranged, which may be closed in a suitable manner at will, and which serve to facilitate observation and regulation of the process of reduction taking place in closed furnaces.—B. N.

Electrodes of electric furnaces; Process and arrangement for bringing the electric current to the ——. Soc. des Carbures Métalliques. Fr. Pat. 402,712, May 5, 1909.

THE connecting rod is provided with a head-piece, conical in shape, and this is bound, in a convenient manner, in a suitable hollow in the carbon forming the electrode. The method is suitable for the electrolysis of melted salts, as, e.g., in the extraction of aluminium.—B. N.

Zinc smelting: Electric —. The Côte Pierron process. E. Fleuryville, La Houille Blanche, 1908, 7, 273. Electrochem. and Metal. Ind., 1909, 7, 468—472.

Fig. 2.

THE Côte-Pierron process consists in reducing zinc sulphide by means of iron in the electric furnace. The furnace adopted on a commercial scale after testing several types, is shown in the illustration. The lower part of the crucible, A, with the projection, b, is made of graphite and is connected with one pole of the electric circuit. The roof is formed of refractory fire-brick and is provided with openings, c, for the introduction of the charge. The zinc vapours pass into the condenser, I, which is filled with particles of carbon. Air is admitted through the opening, j, to raise the falling carbon to a red heat so that at a point lower in the condenser, the zinc "mist" may be reduced. The furnace was also used for the manufacture of zinc oxide by passing the zinc vapour to a combustion apparatus and collecting the oxide in settling chambers. The results of a run were:—Time of experiments, 240 hours; weight of ore smelted, 14,560 kilos.; average content, 43.6 per cent. of zinc; weight of iron used, 6235 kilos.; weight of fluxes added,

3480 kilos.; mean current, 4300 amps.; E.M.F., 40 volts; power factor, 0.80; weight of zinc oxide obtained, 6730 kilos.; metallic zinc condensed, 182 kilos.; zinc content of the slag and iron sulphide, 2.7 per cent.; consumption of electrodes, 193 kilos.; cost of electric energy, 65 francs (£2 11s. 6d.) per H.P.-year. For the production of commercial white zinc oxide, free from iron, which cannot be obtained by the process described, the reaction of lime and carbon with zinc sulphide, was utilised:

The furnace used was formed of a graphite crucible, 110 cm. diam. inside, 65 cm. high. The results obtained were:

Time of running, 600 hours; weight of ore smelted, 28,345 kilos.; current, 3800 amps.; E.M.F., 42 volts; power factor, 0.85; lime, 12,384 kilos.; carbon, 3146 kilos.; consumption of electrodes, 1286 kilos.; zinc content of charge, 10,587 kilos.; zinc oxide obtained, 12,370 kilos.; cost of manufacture, 4598 francs (£182 7s.).

The zinc oxide obtained contained 98.6—99.0 per cent. of zinc oxide and 0.2—0.3 per cent. of iron. According to its whiteness the oxide was divided into two brands, 70 per cent. being of the better quality.—J. W. H.

PATENTS.

Electro-deposition of metals: Apparatus for —. T. A. Smith and T. Deakin, Walsall. Eng. Pat. 21,687, Oct. 14, 1908.

A STATIONARY tank, a (see Fig.), contains the plating solution and the anodes, c. A barrel, d, containing the material to be plated, is arranged to rotate in this tank with its axis at an angle of 35° or 40° to the horizontal. The lower end of the barrel is entirely closed. The cathode connection is made by means of a brush or other device, though the wheel, h, the rod, n, n², n³, in the axis of the barrel, to a number of arms, m, on the base of the barrel. The axle is encased in fibre to prevent contact with the material being plated. The barrel is rotated by means of the worm wheel, k, and may be lifted from the tank by releasing the adjustable screw, i. This construction admits of the work being removed through the open end of the barrel, at any time during the process, for examination.—J. W. H.

Electro-plating apparatus. R. Walker and W. C. Pinson, Wolverhampton. Eng. Pat. 12,482, May 26, 1909.

THE claim is for a basket for holding the articles to be plated, consisting of a wooden frame, suspended in the bath by wires and having a bottom of wire gauze. Bars are placed across the wooden frame, above the articles, to support the anode. Electrical connections are made to the wire gauze and the anode.—J. W. H.

Reducing metallic compounds [electrically]: Method of —. F. J. Torpe, Niagara Falls, N.Y. U.S. Pat. 937,120, Oct. 19, 1909.

METALLIC or silicon compounds, which are subject to volatilisation losses at the temperature of reduction, are reduced by supporting a charge of the compound and a reducing agent, on a hearth which is impervious to the charge but pervious to the products of reduction. An electric arc, of sufficient intensity to reduce the compound, is maintained within the charge, so that the temperature

of the latter, between the hearth and the reduction zone, is kept below the volatilisation temperature of the silicon or metal. The fused product is removed from the reduction zone, and allowed to pass through the hearth to a receiving space below, in which it is maintained in a fused condition.—B. N.

Mercury; Method of oxidising metals dissolved in —. J. Whiting, Boston, Mass., and C. F. Burgess, Madison, Wis., Assignors to The Whiting Co., Boston, Mass. U.S. Pat. 937,128, Oct. 19, 1909.

A SERIES of carbon surfaces is arranged at the bottom of a containing tank and exposed to an oxidising electrolyte; and a moving body of the amalgam is placed in electrical contact with the carbon surfaces by means of a relatively quiescent body of comparatively pure mercury underlying the amalgam.—F. R.

[Silver] *Precious metals; Process of recovering* —. J. H. Reid, Newark, N.J. U.S. Pat. 937,387, Oct. 19, 1909.

ARGENTIFEROUS ores, containing nickel and cobalt or the like, are finely powdered, mixed with lead and a flux and passed through an electric arc. The volatile products are removed by suction and the molten metal and flux are rotated, in order to effect a separation by gravity.

—F. R.

XII.—FATTY OILS, FATS, WAXES, AND, SOAPS.

Mixed triglycerides; Synthesis of —. (Synthesis of fats. III.). A. Grün and A. von Skopnik. Ber., 1909, 42, 3750—3759. (See also this J., 1907, 536).

TRIGLYCERIDES containing three different acid radicals in any desired order can be prepared by replacing in succession the primary hydroxyl group, the chlorine atom, and the secondary hydroxyl group of α -monochlorhydrin by different fatty acid radicals. The authors have prepared in this way the three isomeric mixed triglycerides of lauric, myristic, and stearic acids. α -Monochlorhydrin was warmed with an equivalent quantity of lauryl chloride, the reaction product dissolved in ether, washed with water and with sodium carbonate solution, dried with fused sodium sulphate, and the ether distilled off *in vacuo*. The α -lauro- α' -chlorhydrin,

this obtained is a faintly yellow, mobile oil at the ordinary temperature, which crystallises from light petroleum spirit at about -10°C . in small, white crystals; it is soluble in the common organic solvents. By treatment with silver nitrite (Ber., 1907, 40, 1792; this J., 1907, 536), it is converted into α -monolaurin,

which forms white, lustrous leaflets, easily soluble in ether and warm petroleum spirit, and soluble with difficulty in alcohol. The crystals melt at 52°C ., but when the melted substance has solidified and is again heated, it melts at $40-41^\circ\text{C}$. β -Monolaurin prepared from β -lauro- $\alpha\alpha'$ -dichlorhydrin, melts at $58-5^\circ\text{C}$. α -Lauro- α' -myristin,

was obtained by heating α -lauro- α' -chlorhydrin with potassium myristate at 140°C . in a current of hydrogen. It can be crystallised from very dilute solutions in a mixture of ether and petroleum spirit below 0°C ., and forms very small, lustrous, white crystals, which are soluble in the ordinary fat solvents; it melts at $40-42^\circ\text{C}$., and after solidification, at $34-35^\circ\text{C}$. When warmed with the calculated quantity of stearyl chloride, it is converted into α -lauro- β -stearo- α' -myristin,

which crystallises from ether in very soft, white crystals, almost insoluble in alcohol. It melts at $37-38^\circ\text{C}$., and after solidification, at 35°C . α -Stearo- α' -chlorhydrin, prepared in a similar manner to α -lauro- α' -chlorhydrin, forms white crystals soluble in benzene, ether, and warm

petroleum spirit; it melts at $48-49^\circ\text{C}$., and after solidification, at $39-40^\circ\text{C}$. α -Stearo- α' -laurin from α -stearo- α' -chlorhydrin and potassium laurate, forms white crystals easily soluble in benzene, chloroform, and ether, soluble with difficulty in alcohol and in cold petroleum spirit; it melts at $52-53^\circ\text{C}$., and after solidification, at 45°C . α -Stearo- β -myristo- α' -laurin prepared from α -stearo- α' -laurin and myristyl chloride forms soft, dull white crystals, which melt at $48-49^\circ\text{C}$. (46°C . after keeping for a long time), and after solidification, at $44-45^\circ\text{C}$. α -Stearo- α' -myristin obtained from α -stearo- α' -chlorhydrin and potassium myristate, softens at 47°C . and melts at $52-53^\circ\text{C}$. (at 44°C . after solidification). α -Stearo- β -lauro- α' -myristin from α -stearo- α' -myristin and lauryl chloride, forms soft, yellowish-white, ill-defined crystals, which melt at 42°C ., and after solidification, at 32°C . The melting points of mixtures of the three isomeric triglycerides are shown in the following table:—

	M. pt. of crystals.	M. pt. after solidification.
	$^\circ\text{C}$.	$^\circ\text{C}$.
Stearolauromyristin + laurostearomyristin ...	39	33

Stearolauromyristin + stearomyristolaurin ...	45	36
Stearolauromyristin + laurostearomyristin + stearomyristolaurin	39—41	37

—A. S.

Olive oil, Tunisian; Reactions of —. R. Marcille. Ann. des Falsific., 1909, 2, 224—239.

OLIVE oils obtained from Northern Tunis frequently yield a reaction with the Villiaveccchia and Fabris test (hydrochloric acid and furfural) which may lead to the conclusion that the oil is adulterated with sesame oil; oils from the Souss and Sfax regions also yield a similar, but less marked, reaction. With a little practice, however, the coloration given by this class of oils may be readily distinguished from that obtained with mixtures of olive oil with sesame oil, and in no case do the oils give a positive reaction in Bellier's test (a mixture of nitric acid, sp. gr. 1.4 with a solution of resorcinol in benzene). This test is, consequently, recommended as a reliable means of ascertaining the absence of sesame oil in olive oils which, from the results of other tests, may be suspected of containing sesame oil. The constituent which gives the reaction with hydrochloric acid and furfural is removed by washing the oil with hot water containing a little sodium bicarbonate, and washing with hot water alone eliminates the greater part of the substance. The quantity of the latter present appears to diminish when the oil is kept; it is found more frequently in freshly prepared oils. (See also this J., 1907, 1185).—W. P. S.

Sesame oil; Furfural reaction for the detection of —. H. Imbert and L. Durand. Ann. de Falsific., 1909, 2, 317—319.

CERTAIN Algerian and Tunisian olive oils give a red coloration with hydrochloric acid and furfural, which might easily be mistaken for the coloration given by sesame oil. Any mistake may be obviated by applying the test to the fatty acids of the oil, or by a preliminary washing with water rendered alkaline with sodium bicarbonate, as proposed by Marcille (see preceding abstract). A sample of pure olive oil containing 1 per cent. of sesame oil still gave a red coloration after being boiled for 5 minutes each time with 6 successive portions of the alkaline solution, whereas the substance in the Tunisian and Algerian olive oils giving a red coloration was readily extracted by boiling with water alone, and especially with water containing bicarbonate.—C. A. M.

Oils obtained by extraction with carbon bisulphide; Detection of — in commercial oils. Cusson. Ann. des Falsific., 1909, 2, 409—410.

ONLY the lowest grade of edible oils are stated to be mixed with oils that have been extracted with carbon bisulphide.

The presence of faint traces of this solvent in an oil may be detected as follows:—About 200 grms. of the oil are thoroughly shaken with 50 grms. of 90 per cent. alcohol, and the flask then connected with a condenser and heated on a water-bath. The distillate is received in a flask cooled in water and containing a little alcoholic potassium hydroxide solution, and the heating is continued until about one-third of the alcohol has distilled. Any traces

practically unlimited quantities. Whether soya-bean oil would find an economic use comparable to that of cottonseed oil remains to be determined, as does also the feeding value of soya-bean meal from which the oil has been extracted.

The relative richness of the soya bean in oil and other constituents as compared with other oily seeds is shown in the following tables:—

Analyses of seeds of seven varieties of soya beans.

Variety.	Fresh or air-dry substance.					
	Water.	Protein.	Fat.	Nitrogen-free extract.	Fibre.	Ash.
	per cent.	per cent.	per cent.	per cent.	per cent.	per cent.
Austin	8.67	36.59	20.55	24.41	4.00	5.78

Kingston	7.45	36.24	18.96	26.28	4.79	6.28
Mammoth	7.49	32.99	21.03	29.36	4.12	5.91
Guelph	7.43	33.96	22.72	25.47	4.57	5.85
Medium yellow	8.00	35.54	19.78	26.30	4.53	5.85
Samarow	7.43	37.82	20.23	23.65	5.05	5.82
Average	7.70	35.40	20.35	26.15	4.60	5.70

Analyses of cottonseed, sunflower seed, and peanuts.

Kind of seed.	Fresh or air-dry substance.					
	Water.	Protein.	Fat.	Nitrogen-free extract.	Fibre.	Ash.
	per cent.	per cent.	per cent.	per cent.	per cent.	per cent.
Cottonseed (whole)—						
Minimum	8.00	13.62	10.40	7.58	17.60	2.89
Maximum	17.51	29.70	29.34	36.70	32.40	8.00
Average of 25 analyses	9.92	19.38	19.45	22.57	22.57	4.74
Sunflower seed (whole)—						
Minimum	8.50	15.80	20.90	22.00	29.50	2.10
Maximum	8.80	16.70	21.50	20.70	30.30	3.20
Average of 8 analyses	8.60	16.30	21.20	21.40	29.90	2.60
Peanut (kernels)—						
Minimum	4.90	23.20	25.00	12.70	2.00	1.90
Maximum	13.20	31.50	47.40	19.10	18.40	3.80
Average of 7 analyses	7.50	27.90	39.60	15.60	7.00	2.40

of carbon bisulphide carried over will be converted into potassium xanthate, which may be detected by rendering the distillate faintly acid with acetic acid, and adding a few drops of an alcoholic solution of copper acetate. A yellow coloration (or precipitate after a short time) of copper xanthate indicates that the oil under examination contained oil obtained by extraction with carbon bisulphide.—C. A. M.

Oil, edible; Adulteration of — with mineral oil. L. Ronnet. Ann. des Falsific., 1909, 2, 220—221.

A SAMPLE of edible oil examined by the author gave the following analytical results:—Sp. gr. at 15° C., 0.8905; refractometer value, 32.5; saponification value, 66.0; iodine value (Hübl), 44.9; Maumené test, 37°; unsaponifiable matter, 66.36 per cent. The oil gave a reaction for sesamé oil, but no indications were obtained of the presence of linseed, cottonseed, or resin oils. As shown by these figures, the sample consisted of a mixture of vegetable oil, 34 per cent., with mineral oil, 66 per cent. The vegetable oil was, probably, poppy-seed oil containing about 6 per cent. of sesamé oil.—W. P. S.

Soya bean oil and meal. U.S. Dept. of Agri. Bull., Oct., 1909. [T.R.]

DURING the past ten years soya-bean meal has been imported into Europe in large quantities from Manchuria, and has met with a ready sale at a price above that of cottonseed meal. This would seem to assure a market for

Bean cake and bean oil in Darien, Japan. Chem. Trade J., 1909, 45, 429—430.

A CHEMICAL analysis of bean cake, as at present prepared, gives the following results:—

	Sample No. 1.	Sample No. 2.	Sample No. 3.
	per cent.	per cent.	per cent.
Water	17.38	16.90	19.10
Oily substances	9.76	9.70	9.18
Albuminous substances	40.98	41.66	45.02
Carbohydrate	20.73	20.64	15.62
Woody fibre	6.65	6.64	6.23
Ash	4.50	4.45	4.78

By the present method, using hand-presses, the amount of oil extracted from the beans is about 8 per cent. At one mill in Darien, which is fitted with hydraulic presses, nearly 10 per cent. can be obtained. The quantity of oil in the soya bean is from 16 to 17 per cent.

Linolic acid. A. Rollett. Z. physiol. Chem., 1909, 62, 410—421.

PURE linolic acid was obtained by converting the crystalline linolic acid tetrabromide prepared from poppy-seed oil into the methyl ester of linolic acid, and purifying this by distillation under reduced pressure. The purified ester was then saponified in the cold by Henriques' method, the sodium linolate solution acidified, and the linolic acid extracted with petroleum spirit. It was a light yellow

oil, which when distilled *in vacuo* yielded a colourless liquid boiling at 229–230° C. under a pressure of 16 mm., and having a sp. gr. at 18/4° C. of 0.9026. (Value hitherto accepted—0.9206 at 14° C.) When brominated the pure acid yielded, at most, 50 per cent. of crystalline tetrabromide, whilst the filtrate contained a syrupy tetrabromide, which on reduction with nascent hydrogen gave pure linoleic acid. On again brominating this acid (from the fluid tetrabromide) 26.2 per cent. of the crystalline tetrabromide was obtained. It was not possible to decide with certainty whether the fluid tetrabromide was identical with the crystalline product, but prevented from crystallisation by traces of impurities, or whether they were individual chemical substances. In any case, however, these experiments prove that the bromine addition method does not give quantitative results, and although valuable as a qualitative test cannot be relied upon for the determination of linoleic acid in mixtures of fatty acids. Further experiments showed that the presence of oleic acid does not reduce the yield of tetrabromide, but that the presence of a large proportion of linolenic acid renders difficult even the detection of linoleic acid. By the oxidation of pure linoleic acid with alkaline potassium permanganate, Hazura's sativic acid (m. pt. 171°–173° C.) was obtained, together with a small amount of another, as yet unidentified substance, which could be extracted with hot benzene. In the author's opinion the foregoing facts, and in particular, the formation of (possibly) isomeric bromine addition compounds corresponding to the same linoleic acid, find an explanation in stereoisomeric relationships arising out of the two double linkages in the molecule of linoleic acid. (See also Lewkowitsch, *Chem. Technol. and Anal. of Oils, Fats, and Waxes*, Fourth Edit., Vol. I., p. 154.)—C. A. M.

Linolenic acid and linseed oil. A. Rollett. *Z. physiol. Chem.*, 1909, 62, 422–431.

A METHOD similar to that of Erdmann and Bedford (this J., 1909, 530) was used in the preparation of linolenic acid from linseed oil. When purified by distillation under reduced pressure and in an atmosphere of carbon dioxide, it was a colourless liquid, boiling between 230° and 232° C. under a pressure of 17 mm., and having an iodine value of 267.4 (theory=274.2). Its sp. gr. at 18°/4° C. was 0.9141, whilst the linolenic acid prepared by Hehner and Mitchell (this J., 1899, 77) had a sp. gr. of 0.9228 at 15° C. When brominated it absorbed 6 atoms of bromine, two of them more slowly than the other four, and yielded about 20 per cent. of a solid hexabromide, and about 80 per cent. of a syrupy liquid, which had the composition of an impure tetrabromide (see this J., 1909, 531). By the further action of bromine, added at intervals of several hours, this tetrabromide was converted in two days into a saturated fluid hexabromide, $C_{18}H_{32}Br_6O_2$, which on reduction with nascent hydrogen yielded linolenic acid. Contrary to the experience of Erdmann, Bedford, and Raspe (this J., 1909, 531), the linolenic acid reduced from this fluid bromide gave, on bromination, a fresh deposit of the solid hexabromide. Moreover, on oxidising pure linolenic acid with alkaline permanganate solution, the author obtained both the linnic and isolinnic acid of Hazura. From these results and a comparison of the yields of hexabromide with the iodine value of the linseed oil from which it was obtained, the author concludes that there is insufficient evidence of the existence of either Hazura's isolinolenic acid or the β -linolenic acid of Erdmann, Bedford and Raspe (*loc. cit.*). The formation of two distinct ozonides upon which Erdmann, Bedford and Raspe base their argument is no more proof of the existence of isomeric linolenic acids than is the formation of different bromine addition compounds. Four addition bromides may theoretically be obtained from a given linolenic acid, and the fact that the experimental yields of solid hexabromide are invariably less than 25 per cent. is therefore quite in accordance with what might be expected.—C. A. M.

Ricinolic acid; Derivatives of —. A. Grün. *Ber.*, 1909, 42, 3759–3763.

THE results obtained by Chonowsky (this J., 1909, 1093) with respect to the action of sulphuric acid on ricinoleic

acid differ considerably from those obtained by previous workers (see Benedikt and Ulzer, *Monatsh. Chem.*, 1887, 8, 208; also Juillard, this J., 1894, 820; 1895, 811). Juillard showed that dihydroxystearic acid is one of the reaction-products, and the author (this J., 1907, 57) showed that this dihydroxystearic acid was a mixture of isomerides, of which he isolated three, one melting at 90° C., having $[\alpha]_D = +6.45^\circ$; and two optically inactive acids melting at 69.5° C. and 108° C. respectively. More recently the author and Wetterkamp have isolated the fourth possible isomeride, which melts at 126° C. Chonowsky's products melting at 73°–74° C. and 115°–116° C. were probably mixtures of the acids melting at (1), 69.5° and 90° C. and (2), 108° and 126° C. respectively. In the formation of dihydroxystearic acids from ricinoleic acid and sulphuric acid, relatively stable inner esters of the type, $C_7H_{13}O_2(OH)_2.CO.O.C_7H_{13}(OH)(COOH)$, are formed as intermediate products (see this J., 1908, 1212; 1909, 1146), and the so-called "glycidic acids" obtained by Chonowsky, of which neither a description nor an analysis is given, may have consisted of these ester-acids or of a mixture of them with dihydroxystearic acids. High-molecular hydroxy-acids show a great tendency to form these inner esters, and hence their production seems much more likely than that of inner ethers (glycidic acids).—A. S.

Cottonseed products; Uniform methods for analysis of —. Oil, Paint and Drug Reporter, Oct. 25, 1909.

AT a recent meeting of the official chemists appointed by the Interstate Cottonseed Crushers' Association, held at Memphis, Tenn., to determine upon a uniform method of analysis, the following methods were decided upon for recommendation:—

Cottonseed meal.

Moisture.—Five grms. dried at 105° C. for two hours in double wall oven (preferably oil bath).

Oil.—Extract 5 grms. of meal (without previous drying) with petroleum ether boiling under 70° C. in a short siphon Soxhlet apparatus for two hours. Evaporate off the ether and weigh the residue as oil.

Optional method.—Oil: Extract 5 grms. of thoroughly dried meal (the portion used for the moisture determination) with petroleum ether boiling under 70° C. in a short siphon Soxhlet apparatus for two hours. Evaporate off the ether and weigh the residue as oil.

Nitrogen. Kjeldahl-Gunning method.—Determination:—(a) Digestion.—1.7 gm. of cottonseed meal are brought into a digestion flask with approximately 0.7 gm. of mercuric oxide (or 0.5 gm. metallic mercury) and 10 grms. of potassium sulphate (free from ammonia) and 25 c.c. of sulphuric acid of 1.84 sp. gr. The flask is placed in an inclined position, and heated below the boiling point of the acid for from 5 to 15 minutes, or until frothing has ceased. The procedure of digestion is now the same as in the regular Kjeldahl method, except that no potassium permanganate is added.

(b) Distillation.—After cooling, the contents of the flask are transferred to the distilling flask with about 300 c.c. of distilled water, a few pieces of granulated zinc, pumice stone, or 0.5 gm. of zinc dust when found necessary to keep the contents of the flask from bumping, and 25 c.c. of potassium sulphide solution are added, with shaking. Next 60 c.c. of soda solution of 1.50 sp. gr. are added, or sufficient to make the reaction strongly alkaline, pouring it down the side of the flask so that it does not mix at once with the acid solution. The flask is connected with the condenser (of block tin), the contents mixed by shaking, and then distilled until all ammonia has passed over into the standard acid, which is an accurately measured quantity of $N/2$ sulphuric acid to which is added about 50 c.c. distilled water. The distillate is then titrated with $N/4$ caustic soda or ammonia solution, using cochineal solution as indicator.

Fatty acids in soap stock.

The following method was adopted as the official method for the determination of total fatty acids in soap stock:—

Total fatty acids—Gravimetric method.—Weigh out 8 to 10 grms. of well-mixed sample into a small extraction flask. Saponify with an alcoholic soda solution over a steam bath and heat, with occasional stirring, until all alcohol is driven off.

Wash out with about 400 c.c. of hot water into a beaker, and digest on the water bath until complete solution of the soap is effected. Acidify with dilute sulphuric acid and continue heating on bath until the layer of fatty acids has become clear. Cool and filter off the liquor from the cake of fatty acids, washing with cold water until no trace of sulphuric acid is left. Allow the fatty acids to dry thoroughly, preferably by standing over night. Transfer the fatty acids to a folded filter paper and place in a Soxhlet extractor. Dissolve fat adhering to beaker with warm gasoline, and extract with redistilled gasoline for three hours. Drive off the gasoline and heat to constant weight. Calculate percentage on original weight.

Note.—Time is saved by chilling the melted fat in running water and by dissolving the majority of the dry fat cake in a beaker and on the filter paper with warm gasoline, allowing to filter through into the tared flask, then wrapping up filter paper and extracting as usual for one and a half hours.

Moisture to be reported.

The committee recommended that a moisture determination be made and reported on all samples of cottonseed meal or cake.

It was moved and adopted that President Allen be requested to warn the members of the Interstate Cottonseed Crushers' Association against using oil sample cans sealed with a linoleum washer or gasket.

The following resolution was adopted:—

"The committee recommends that the rule in regard to sending samples in air-tight cases be rigidly enforced as a step toward securing more accurate and uniform analytical results. It is the unanimous opinion of the committee that a very large percentage of the discrepancies in chemical analyses is due to carelessness in the preparation and preservation of samples."

Next followed a discussion of the present method of determining refining losses in crude oil, and it was decided to make no changes at the present time, except the following, and the method now and in use for the past two years be continued.

"After the addition of the caustic soda solution a more thorough and vigorous agitation of the oil is recommended until all the caustic soda solution is thoroughly incorporated throughout the oil. Allow oil to stand for three hours at 125° F. before cooling and draining, instead of one hour as formerly."

Beeswax; French Codex test for foreign fats, resins, and waxes in.—P. Le Naour. Ann. Chim. analyt., 1909, 14, 369—370.

THE official test of the French Codex, 1908, specifies that when 1 gm. of beeswax is boiled for 30 minutes with 35 c.c. of aqueous, 15 per cent. sodium hydroxide solution, the amount of water lost by evaporation being replaced by the addition of hot water, the liquid, cooled and strained through absorbent cotton, should not give a precipitate when acidified with hydrochloric acid. This result is taken to indicate freedom from admixture with foreign fats, waxes, and resins. The test is found to be defective. No precipitate is obtained, under the conditions indicated, even when fragments of a stearic candle are thus treated, nor if 20 per cent. aqueous potassium hydroxide be substituted for the sodium hydroxide solution for saponifying. But if saturated solution of sodium carbonate be used in place of the hydroxide, sodium stearate is formed, solidifying on cooling, but re-dissolving on warming; on acidifying with hydrochloric acid, stearic acid is liberated.—J. O. B.

Hydroxyfatty acids; Process for the preparation of—from the addition compounds of hypochlorous acid or chlorine with the glycerides of vegetable or animal oils. G. Imbert and Consortium für elektrochem. Ind. Ges.m.b.H. Ger. Pat. 214,154, March 29, 1908. Addition to Ger. Pat. 208,699, Sept. 22, 1906.

IN the process described in the main patent (see Fr. Pat. 368,543 of 1906; this J., 1907, 25), hydroxyfatty acids were prepared from the addition compounds of hypochlorous acid or chlorine with fatty acids, by heating them with alkali, alkali carbonates, or alkaline-earths under pressure. According to the present patent, the addition-compounds of the glycerides are used and a further quantity of alkali carbonate or bicarbonate, necessary for the saponification of the glyceride, is added.—A. S.

"Oleine-vaseline" and "vaseline-grease" for lubrication obtained by extracting the mucilaginous principle from a mixture of sea-weeds. C. de la Guéronnière. Fr. Pat. 402,095, Apr. 16, 1909.

A MIXTURE of the chief mucilaginous seaweeds (*Fucus crispus*, 75; *pearl fucus*, 20; and agar-agar, 5 per cent.), previously freed separately from ligneous tissue and boiled with hot water containing 10 per cent. of sodium chloride and 5 per cent. of potassium carbonate, is gently boiled with a 10 per cent. solution of sodium chloride until solution occurs. For "oleo-vaseline" from 700 grms. to one kilo. of the mixture is used with 100 litres of aqueous solution, whilst for "vaseline-grease" twice that proportion of seaweed is required. The solution is filtered hot, and preserved by the addition of turpentine oil, alcohol, sulphurous acid, or phenol, etc.—C. A. M.

Soaps containing solvents for fats; Preparation of—A. Welier. Fr. Pat. 402,172, Apr. 17, 1909.

TO obtain soaps containing at least 3 per cent. of a fat solvent (e.g., turpentine oil, or ethylene perchloride) it is necessary to use as the base soaps containing not more than 30 per cent. of fatty acids (or 55 per cent. in the case of castor oil soaps). The proportion of fatty acids in commercial soaps may be reduced to the necessary extent by the addition of water; or a solution of free fatty acids in the required solvent may be saponified with a potash lye and incorporated during the process with water. Only in the case of soaps prepared from castor oil fatty acids can caustic soda or ammonia by themselves be used for the saponification. It is essential during the saponification to exclude as far as possible the usual additions of alkali salts, such as potassium or sodium carbonates, chlorides, sulphates, etc. In this way it is possible to obtain soaps containing (partially in a state of solution) 20 to 25 per cent. of ether, acetone, carbon tetrachloride, etc., and yet soluble in water.—C. A. M.

Soaps containing mercury compounds; Production of—Farbenfabriken vorm. Bayer and Co. Fr. Pat., 402,740, May 5, 1909. Under Int. Conv., May 19, 1908.

ORDINARY soaps are incorporated with alkali salts of complex mercuric substitution compounds of carboxylic acids of the aliphatic or aromatic series, such as, e.g., the sodium salt of oxymercuri-acetic acid, $\text{OH.Hg.CH}_2\text{COONa}$, or of oxymercuri-salicylic acid, $\text{HO.Hg.C}_6\text{H}_4(\text{ONa}).\text{COONa}$.—C. Oil of turpentine; Composition of —. E. Darmais.
Comptes rend., 1909, 149, 730—733.

Not only the dextro-rotatory (this J., 1908, 866) but also the levo-rotatory turpentine oils consist of a mixture of a compound of high and a compound of low, dispersive power. The latter is in all cases levo-rotatory, and is the same substance whether the oil as a whole be dextro- or levo-rotatory. Its specific rotatory power is $[\alpha]_D = -21.7^\circ$. It probably forms about 38 per cent. of oil of turpentine, the remainder being one or other of the forms of pinene.

Japan lac; Main constituent of —. II. Oxidation of the dimethyl ether of urushiol with ozone. R. Majima.
Ber., 1909, 42, 3664—3673.

In previous investigations (this J., 1907, 1245; 1909, 532) it was concluded that urushiol had the composition, $C_{20}H_{30}O_2$, and the constitution of a divalent phenol with an unsaturated aliphatic side-chain. Further evidence as to the constitution of urushiol and the position of the double linkages in the side chain has been obtained by the ozonisation of its dimethyl ether. When this compound was treated with strong (14 to 18 per cent.) ozone at a low temperature, it yielded a tetra-ozonide, $C_{22}H_{34}O_{12}$, in the form of a light yellow semi-solid mass, which exploded violently when heated even to $60^\circ C$. When boiled with glacial acetic acid it was decomposed, the products of the decomposition including acetaldehyde, oxalic acid, α -naphthol and azelaic acid. It is probable that part of the ozone in this ozonide is in direct combination with the aromatic nucleus of the dimethylurushiol mol. This view is supported by the fact that methyleugenol, which is known to contain only one double linkage in its allyl group, forms a very explosive triozonide on treatment with concentrated ozone. When, however, more dilute (about 6 per cent.) ozone is used, only the side-chain of methyleugenol is attacked, and a mono-ozonide is obtained. In like manner, dimethylurushiol reacts with 6 per cent. ozone to form chiefly a di- or triozonide, according to the duration of the treatment. If, in the triozonide, all three ozone mols. are in the side-chain, the latter must have the composition, $-C_{11}H_{23}$, and the formula of urushiol itself must be $C_{20}H_{28}O_2$. It is not yet possible to come to a definite conclusion on this point. Dimethylurushiol diozonide was a fluid substance, which was much less explosive than the tetra-ozonide. On decomposition with hot water it yielded acetaldehyde, carbon dioxide, α -naphthol, and a substance containing 2 methoxyl groups in its mol., together with slight amounts of azelaic and oxalic acids. In the decomposition with cold water, acetaldehyde and the semi-aldehyde of malonic acid appeared to be the primary products. The triozonide was a light yellow substance which exploded with some violence when heated in a flame. On treatment with water it yielded the same products of decomposition as the diozonide, but with increased yields of azelaic and oxalic acids. In the author's opinion it is possible that dimethylurushiol is not an individual substance, but consists of at least two closely-allied compounds with isomeric side-chains, the relationship being comparable to that of eugenol and iso-eugenol.—C. A. M.

PATENT.

Linoxyn and like products; Process of manufacturing especially intended for utilisation in the manufacture of linoleum and like products. A. Genthe, Goslar, Germany. Eng. Pat. 1990, Jan. 27, 1909. Under Int. Conv., Feb. 26, 1908.

XV.—MANURES, &c.

Soil; Effect of partial sterilisation of — on the production of plant food. E. J. Russell and H. B. Hutchinson. J. Agric. Science, 1909, 3, 111—144.

It has been known for many years that when soil is partially sterilised, either by heat or by volatile antiseptics such as carbon bisulphide, toluene, etc., it becomes more productive and capable of yielding larger crops. Darbishire and Russell (J. Agric. Science, 1908, 2, 305) have shown that the property is a general one, holding for all kinds of soil and for all plants except those of the leguminous order. Moreover not only is a better crop obtained (two, three or even four times as much after heating, and an increase of from 20 to 50 per cent. after treatment with antiseptics), but the plants contain more nitrogen and phosphorus than those grown on untreated soils. The authors have studied exhaustively the effects of heating to 98° C., and of treatment with 4 per cent. of toluene on two different soils, one of which had been unmanured for many years, whilst the other had received occasional dressings of artificial manures since 1902. After treatment, the soils were moistened and kept in bottles stopped with cotton-wool, when it was found that in the partially sterilised soils there was a small immediate production of ammonia, then after a period of little change, a rapid production of ammonia, followed in turn by a period of slow production; in one month about 40 parts of nitrogen per million parts of soil had been converted into ammonia. In untreated soil there was no accumulation of ammonia, whilst when after the treatment with toluene, the latter was allowed to remain in the soil, there was only a slow production of ammonia. The production of ammonia is mainly due to the work of micro-organisms, the presence of moisture is essential, and in soil which has been completely sterilised by heating to 125° C., after the initial formation of ammonia due to the effect of heat, no further quantity is produced. The production of unstable nitrogen compounds (those decomposed by boiling with water and magnesia) is also accelerated by partial sterilisation, but that of humus is hardly affected. Nitrifying organisms are destroyed by the treatment, but if they are subsequently introduced, nitrification at once begins in the soils which have been treated with toluene, but not in those which have been heated. The amount of total nitrogen in the soil is not greatly affected by the treatment, the most significant effects of which are the increased production of ammonia, and the cessation of the nitrifying process. Bacteriological investigation showed that after the partially sterilised soils are moistened, bacteria multiply more rapidly and become much more numerous than in untreated soils, and this increase of bacteria proceeds *pari passu* with the increased production of ammonia. On adding a filtered extract containing bacteria from an untreated soil to a partially sterilised soil, there was an increase in the rate of production of ammonia and in the

number of bacteria, but no such increase was observed on adding the untreated soil itself to the partially sterilised soil, or on adding an extract of the treated soil to the untreated soil. The conclusion is drawn therefore that the untreated soil contains a factor, not bacterial, limiting the development of bacteria, this factor being rendered non-effective by heating and by treatment with toluene. It was found that large organisms—*protozoa*, etc.—are present in the untreated, but not in the partially sterilised soils; some of them are known to destroy bacteria, whilst all of them, by reason of their large size, must be severe competitors. It is these large organisms, which, in the opinion of the authors, limit the bacterial activity, and hence the fertility of untreated soils, a condition of equilibrium being established between the large organisms and the bacteria, beyond which the latter cannot multiply. On partial sterilisation the large organisms are killed, but the bacterial spores are not, and subsequently, in presence of moisture, the spores germinate, and the resulting bacteria multiply with great rapidity, not being subject to competition or to the attacks of their enemies. The new species of bacteria appear to be somewhat less active than the old races, but owing to their enormously greater numbers, there is a largely increased amount of ammonia produced.—A. S.

Calcium carbonate in soils; Determination of —. F. S. Marr. J. Agric. Science, 1909, 3, 155—160.

WHEN the amount of calcium carbonate in soils is determined by means of the amount of carbon dioxide evolved on boiling with dilute (1:1) sulphuric acid, abnormal results are obtained in the case of soils containing a high proportion of humus and having an acid reaction towards litmus. Experiments showed that this is due to the evolution of carbon dioxide from the organic matter of the soil by the action of boiling acid. Where the proportion of calcium carbonate is relatively high, the error introduced in this way is not very considerable, but the reverse is the case with soils, especially acid soils, containing less than 1 per cent. of calcium carbonate. The error can be reduced considerably by using weaker acid, for example 5 c.c. of strong hydrochloric acid (2 c.c. in the case of acid soils or those poor in calcium carbonate) to 100 c.c. of water; whilst by boiling under diminished pressure—for 20 minutes at about 50° C.—the calcium carbonate can be readily decomposed, with practically no evolution of carbon dioxide from the organic matter.—R. C. P.

Ammonium salts; Direct assimilation of —, by plants. H. B. Hutchinson and N. H. J. Miller. J. Agric. Science, 1909, 3, 179—194.

ADDITIONAL evidence of direct assimilation of ammonium salts by plants seems desirable, the question possessing a further interest in the case of leguminous plants, since whilst non-leguminous crops (whether able to assimilate ammonia or not) undoubtedly take up, under normal conditions, most of their nitrogen in the form of nitrates, there is no conclusive evidence as to the form of nitrogen appropriated by leguminous plants from their root nodules. The experiments described by the authors comprise sterilisation of seeds; observations of wheat grown in sand and water cultures; peas growing in water culture; and determination of percentage of nitrogen in the mixed herbage of the Rothamsted grass plots. Sterilisation was found to be best effected by treating the seeds in a warm mercuric chloride solution after removal of air-bubbles by means of a vacuum pump, and washing in sterilised water. The sterilised seeds were transferred to Petri dishes and a sterilised solution of agar was poured in; on solidification, the plates were inverted and placed in an incubator at 20° C. The plants having germinated and attained roots from 1 to 1½ inches length, in 3 or 4 days, were transferred to sterile wide test-tubes containing distilled water over which a plug of cotton wool had been placed. On this cotton wool the seedlings were allowed to grow until the shoot was approximately 3 inches long; and they were carried over to the culture bottles at the end of 7—8 days. The culture bottles used were three-necked Woulff's bottles provided with means of aerating the contents or introducing more water as required, while

maintaining sterile conditions. A series of Woullf's bottles were filled with a solution of non-nitrogenous salts, and nitrogen was added in the form of ammonium sulphate or sodium nitrate to the contents of some of the bottles. The contents of other bottles, again, were inoculated with nitrifying organisms. At the end of each experiment the dry matter of the plants, the total nitrogen in the crop and the nitrogen in the dry matter were tabulated for each bottle. From the results obtained, the authors deduce the following conclusions:—Agricultural plants of various kinds can produce normal growth when supplied with nitrogen in the form of ammonium salts under conditions which exclude the possibility of nitrification. Some plants grow equally well with ammonium salts or nitrate as source of nitrogen. Other plants, while assimilating ammoniacal nitrogen in the absence of nitrates, appear to prefer nitrates. It is less certain whether ammonium salts can ever produce better final results than nitrates, although there are indications that this may be the case. Lehmann (Biedermann's Centrallbl., 1875, 7, 403) found that whilst buckwheat failed to grow well with ammonium salts, maize did far better with this form of nitrogen than with nitrates during the first period of growth. Later on the nitrate plants recovered, and the ammonia plants became unhealthy. Kellner (Landw. Vers.-Stat., 1884, 30, 18) showed that paddy rice also prefers ammonium salts to nitrates to commence with, and that nitrates are better than ammonium salts for later growth. The best results of all were obtained when both forms of nitrogen were employed together. Plants which take up nitrogen exclusively in the form of ammonium salts generally contain very distinctly higher percentages of nitrogen than when supplied with nitrates. The question arises whether the high percentages of nitrogen in leguminous plants may be due to the nitrogen—or most of it—being assimilated in a form more suited to the rapid production of proteids than nitrate.—R. C. P.

Basic slag; Amount of free lime and the composition of the soluble phosphates in —. C. G. T. Morison. J. Agric. Science, 1909, 3, 161—170.

IN four samples of basic slag examined, the amount of lime present both as carbonate and oxide did not exceed $7\frac{1}{2}$ per cent. To determine what influence this amount of free lime had on the action of the solvents employed for determining the soluble phosphoric acid, a solution of carbon dioxide approximately saturated at atmospheric pressure, was first employed. With this solution five successive extractions were made on each of four samples of slag; the quantity of phosphoric acid dissolved in no case amounted to 70 per cent. of the total; and the proportion was very much the same for all the slags. It would appear, therefore, that the easily soluble constituent is the same in each case. Since, the first action of the carbon dioxide would almost certainly be the conversion of the free lime into carbonate, it would be expected that the slag containing the least quantity of free lime should show the highest percentage of phosphoric acid soluble at the first extraction. This is precisely what occurs. Thus owing to the small mass of carbon dioxide entering into the reaction, the extent to which the phosphates are attacked is masked by the presence of varying quantities of free lime. Hence it follows that although the natural solvent in the soil is carbon dioxide, it is not possible to make use of it as a solvent for the determination of soluble phosphoric acid in basic slag. Further determinations were made of the amount of phosphoric acid soluble in a 1 per cent. solution of citric acid. Here in presence of a much larger mass of acid, the small amount of lime has no longer any effect. In three out of the four slags as much as 93—97 per cent. of the total phosphoric acid present was dissolved. In the case of samples which gave the same percentage of total phosphoric acid soluble in carbon dioxide solution, the proportions soluble in citric acid were vastly different. Experiments showed that fine grinding of the slag resulted in a marked effect in the ease of treatment with citric acid, but not with carbon dioxide solution. Thus it would appear that there are at least two sources of phosphoric acid, one of which is very readily soluble in a weak acid like carbon dioxide, and one or

more which are attacked by citric acid to an extent depending on the amount of surface exposed. After discussing the evidence as to the composition of the soluble phosphoric compound in basic slag, the author states that his results, together with those of Stead (Proc. Cleveland Inst. of Engineers, 1895) show that this is not tetra-calcium phosphate, but a body in which the molecular ratio of phosphoric acid to lime is 1:5. This body is probably a substance of the composition $(\text{MO})_5\text{M}_2\text{O}_5\text{SiO}_2\text{I}_2\text{O}_5$, where M is calcium more or less replaced by ferrous iron, and M_2 is ferrous iron. This coincides with the opinion of Kroll (Stahl und Eisen, No. 19, May 6, 1908).—R.C.P.

Nitrates from the atmosphere; Manufacture of — by the electric arc —. Birkeland-Eyde process. S. Eyde. J. Soc. Arts, 1909, 57, 568—574.

THE author gives a description of the present method of carrying out the Birkeland-Eyde process for the utilisation of atmospheric nitrogen at Notodden, Norway (see also this J., 1906, 27, 567; 1907, 175, 290). There are 36 furnaces installed in a furnace-house constructed of masonry and iron; 32 of the furnaces are supplied from the Svalgfos and 4 from the Tinfos power station, the current being transmitted by means of 18 copper wires of 12 mm. diam. These wires pass to oil-cooled current-transformers in the furnace-house, each of which is furnished with an induction coil in order to regulate the supply of power to the furnaces. The furnaces are constructed of cast steel and iron, lined with fire-brick so as to form a circular reaction-chamber, into which the water-cooled electrodes of thick copper tubing project radially. The electrodes need renewal every third or fourth week, and the furnace lining every fourth or sixth month. The temperature of the arc flame is about 3500°C . The reaction-products leave the furnace at a temperature of $800^\circ\text{--}1000^\circ\text{C}$. and are led through two large pipes, 2 m. diam., to four boilers where their heat is utilised in generating steam, which is used among other purposes for evaporating the liquors obtained subsequently, and, in winter, for warming the buildings. The gases then pass through a large number of aluminium tubes, cooled by flowing water, into iron cylinders, lined with acid-proof stone, where the oxidation of the nitric oxide is completed, and next to the absorption towers, packed with quartz. The first set of towers is constructed of granite and fed with water, and the final tower or towers are built of wood and fed with a solution of soda. The passage of the gases from the furnaces through the towers is effected by means of aluminium centrifugal fans. In the granite towers the absorbing liquid is circulated until it contains 35 per cent. of nitric acid by volume, when it is run into granite cisterns, and thence into granite vats containing limestone. The resulting calcium nitrate solution is evaporated in a vacuum apparatus and then either run into thin iron drums, or into shallow iron pans. In the latter case the hard brittle mass obtained is broken, crushed, and packed into paper-lined casks. The sodium nitrite solution from the wooden towers is concentrated and allowed to crystallise.

Trials of the calcium nitrate as a fertiliser have been made in Norway, Sweden, France, Germany, Austria-Hungary, Italy, and the United Kingdom, and it is stated that for a given quantity of nitrogen, it is quite equal to sodium nitrate, and indeed superior on soils deficient in lime.—A. S.

Hydro-electric nitrogen works at Notodden, Norway. Engineering, Nov. 5, 1909.

DURING the first two years after the Birkeland-Eyde process (see preceding abstract) was started in Norway, the production of calcium nitrate amounted to about 2000 tons per annum, the whole of which, with the exception of a few trial lots sent to England, was disposed of in Scandinavia and on the Continent. Since the new factory at Notodden has been in operation the output has amounted to about 20,000 tons per annum. Vast resources in the way of water power have, however, now been acquired, and large works are being constructed where it will be possible to utilise the power of the famous

Rjukanfos, the energy of which is estimated at about 250,000 horse-power. When these works are finished it is expected that the annual output of calcium nitrate will be 100,000 tons, and this amount will probably increase rapidly as time goes on.

Bean cake and bean oil in Darien, Japan. See XII

PATENT.

Nitrophosphate; Manufacture of manure from —. Le Nitrogène (Soc. Anon.). Fr. Pat. 402,688, May 4, 1909. Under Int. Conv., May 13 and June 20, 1908.

CALCIUM nitrophosphate, resulting from the action of nitric acid on tricalcium phosphate, is mixed with sufficient lime or calcium carbonate, to convert all the phosphoric acid present into its tricalcium salt, and the excess of water present is fixed by the addition of the requisite amount of quicklime or anhydrous calcium nitrate.—O. R.

Utilising waste substances in sugar cane plantations. Eng. Pat. 15,093. See XVI.

XVI.—SUGAR, STARCH, GUM, &c.

Sugar in beetroots, beet juices, and sugar-house products; Influence of optically active non-sugar on the polarimetric results in the determination of —. O. E. Kopecky. Z. Zuckerind. Böhm., 1909, 34, 44—57, 99—115. (Compare Neumann, this J., 1906, 858.)

THE author's conclusions, based on observations extending over 6 years, are essentially as follows:—Differences exist between the direct polarisation and the Clerget value of beet juices and all sugar-house products: with beetroots, the amount of difference depends on climatic conditions during cultivation. The differences are caused by dextro-rotatory non-sugars (which do not consist only of raffinose, dextrose, or asparagin). These substances do not appear to be precipitable by basic lead acetate, but are removed or decomposed by barium hydroxide: they do not reduce Fehling's solution and are strongly melassagenic. Since the polarisation differences vary at different stages of manufacture, it may be supposed that the substances responsible for these differences belong to different groups of dextro-rotatory non-sugars, some being removed in the course of manufacture, whilst others pass more or less unchanged into the final products. Amongst the non-sugars which cause the polarisation differences, are compounds which yield mucic acid on oxidation with nitric acid: the nature of these compounds (or compound) has not, however, been determined. These polarisation differences sometimes cause the high polarisations and purities observed in beet juices, and the very high, untraceable loss of sugar which often occurs in sugar-houses. The use of the method of direct polarisation for factory control is not admissible in cases where polarisation differences occur. Hence, the factory products should always be examined for such polarisation differences, or else the Clerget method should be used exclusively: a new method which would be expeditious and trustworthy is much to be desired (compare Herles, this J., 1908, 1168; 1909, 32). Polarisation differences must be regarded as an abnormal phenomenon, unknown, or too small to be noticeable, in earlier years.—L. E.

Sulphurous acid [in sugar juices, etc.]; Conversion of — into sulphuric acid. Saillard and Wehrung. Suppl. à la Circul. hebdom. du Synd. des Fabr. de Sucre de France, 1909, No. 1057; Deutsche Zuckerind., 1909, 34, 843.

THE authors' experiments show that the oxidation of alkali sulphites to sulphates by the passage of a current of air through the solution, is retarded by the presence of various other substances (e.g., sucrose, invert sugar, the non-sugar of sugar-house products). In the case of sugar-house liquors, this oxidation is slowest in molasses. The tendency to oxidation increases with the content of air

in the gas used for sulphitation: trouble from this cause, however, is avoided by keeping the solutions alkaline and in a state of continuous motion, though it is preferable to use liquefied sulphur dioxide for sulphitation.—L. E.

[Cane] Molasses; Observations on —. H. A. Tempany. West Ind. Bull., 1909, 10, 139—142.

The froth fermentation of molasses.—The mode of frothing varies according to the nature of the product. With muscovado molasses, evolution of gas generally begins suddenly, ceasing in two or three days and sometimes in a few hours. With vacuum-pan molasses, evolution of gas generally continues for relatively long periods; it is almost invariably accompanied by the rising of a thick black scum, and always, apparently, by true fermentative changes. The author shows that the conditions giving rise to frothing cannot be communicated by inoculation; hence, frothing is not due to the action of organisms. He confirms the suggestion of Prinsen-Geerligs that frothing is due to decomposition of gummy substances (glucanates) formed by the action of lime on glucose. In vacuum-pan molasses, these gums, in course of time, generally rise to the surface in an impure state (the above-mentioned scum); they contain more ash than the molasses itself. It is suggested that these gums, being insoluble, may adversely affect the recovery of sugar from second massecuites by forming a coating on the small sugar crystals. This can be avoided to some extent by allowing the massecuite to stand undisturbed, when the gums rise to the surface. It is also suggested that the reason why juices from canes grown on certain highly calcareous soils are very liable to give extremely gummy products, is that the excess of lime in the soil increases the amount contained in the juice, and gives rise to additional formation of glucanates. *The souring of molasses.*—Solutions containing sucrose, small quantities of invert sugar and traces of plant food constituents, were inoculated with various kinds of fermenting molasses, and examined after the lapse of 5 weeks. Various organisms were found to develop (*Bacillus pasteurianus*, in two cases) and considerable quantities of reducing sugars were formed. The changes likely to occur in molasses as a result of organic activity are illustrated by examination of fermenting second vacuum-pan molasses. It was found that a decrease in the total sugar-content as well as a conversion of sucrose into reducing sugar, and a decrease in the ash-content occurred: the last is probably to be traced to glucanates being thrown out of solution. The changes in the composition of molasses, due to fermentation, are almost invariably accompanied by undesirable alterations in flavour. Muscovado molasses appears to be less liable to these changes than exhausted vacuum-pan molasses: since, at present, however, muscovado molasses is the most valuable product of the cane sugar industry, any risk of such changes should be carefully guarded against.—L. E.

Lactose; Action of calcium hydroxide on —. H. Kiliani. Ber., 1909, 42, 3903—3904.

CONTRARY to an earlier statement (Ber., 1885, 18, 631), the formation of iso-, meta-, and para-saccharinic acids by the action of calcium hydroxide on lactose, may be accelerated by heating, without any serious decrease in the yield. The modified method is as follows:—One part of lactose, dissolved in 9 parts of water, is treated with 0.2 part of calcium oxide (previously slaked and cooled), the whole being frequently shaken in a closed flask for 2 days. After a further period of 24 hours, the clear solution is poured into another flask, and the latter is immersed, to the level of its contents, in water. The water is heated to boiling as quickly as possible, and kept at this point for 10 hours. A bulky dark precipitate (about 45 grms. from 1 kilo. of lactose, containing uncrystallisable substances and much calcium carbonate) is formed; the dark-red filtrate from this precipitate is concentrated to 3 parts (referred to the lactose), whereupon calcium isosaccharinate, mixed with a little calcium carbonate, separates (1 kilo. of lactose

yielded 199 grms. of calcium isosaccharinate). The mother-liquor is decomposed with the calculated quantity of oxalic acid; the acid solution is evaporated to a thick syrup, the latter being extracted once with 4 volumes of a mixture of absolute alcohol (1 part) and dry ether (4 parts). The residual syrup is dissolved in about 10 parts of water and boiled with barium carbonate for 2 hours in a capacious flask. The solution thus obtained, is concentrated to a weight equal to that of the lactose employed, saturated with alcohol, seeded with barium meta- or para-saccharinate, and left to stand under conditions precluding evaporation. After 4 days, the author thus obtained 141 grms. of a mixture of barium salts from 1 kilo. of lactose. That this mixture consisted of meta- and para-saccharinate was proved by decomposing it with the requisite quantity of sulphuric acid, evaporating the solution to a syrup, whereupon the metasaccharin crystallised out, and converting the residue into the brucine salt of parasaccharinic acid (Ber., 1909, 42, 2609). Since the constitutions of the saccharinic acids are established, the author recommends the following names for them:—*a*-Methylol- α , γ , δ -triolpentane-acid for isosaccharinic acid, α , γ , δ -tetrolhexane-acid for metasaccharinic acid, α -ethyl (ω -ol)- α , β , γ -triolbutane-acid for parasaccharinic acid, and α -methyl-tetrolpentane-acid for Peligot's saccharinic acid.—L. E.

Adsorption of certain bases by soluble starch. A. Reyckler. Bull. Soc. Chim. Belg., 1909, 23, 378—383.

THE author subjects the results of Fouard (this J., 1907, 832; 1908, 238, 635, 1215; 1909, 433, 898) to mathematical analysis and criticism and arrives at the conclusion that, according to Fouard's figures, the reactions between soluble starch and bases take place according to Guldberg and Waage's Law of mass action, and are therefore chemical in nature. He considers it probable that starch forms compounds similar in character to alcoholates.

—E. F.

PATENTS.

Waste substances in sugar cane plantations; Utilisation of — and the manufacture of a manure therefrom. W. P. Thompson, London. From J. F. J. Van der Kolk, Java. Eng. Pat. 15,093, June 28, 1909.

MOLASSES is mixed with the ash of cane bagasse, filter-press mud, and finely ground raw bagasse so as to form a practically dry powder which may be used as a fertiliser for sugar canes.—W. P. S.

Sugar house and distillery; Process for charging the diffusers used in the —. L. A. Lambert. Second Addition, dated Aug. 20, 1908, to Fr. Pat. 396,628, Jan. 31, 1908 (this J., 1909, 617, 898).

CLAIM having been made for the application of the process described in the original patent to a circular battery, that claim is now extended to a line diffusion battery ("batterie en ligne"). The employment of a pump for transferring the mixture of cosettes and juice to the diffuser which is to be charged, is avoided by placing the vessel, in which the mixing is effected, above the battery.—L. E.

Beetroot juice; Process and apparatus for mixing, double extraction, and progressive and continuous exhaustion especially applicable to —. E. Viez. Fr. Pat. 401,759, Jan. 29, 1909.

THE material (e.g., beetroot pulp or cosettes) is mixed with the solvent (e.g., beetroot juice, water, or vinasse), and the whole is pumped through the pipe, *f*, into the lower part of the vessel, *A*. This vessel consists of two juxtaposed vertical columns, *a*, and is provided with a perforated false bottom, *c*. Part of the liquor flows through the false bottom to the outlet, *e*, below; the remainder, with the solid matter, passes upwards, meeting a descending stream of solvent introduced through the pipes, *h*. Extraction is facilitated by the action of stirrers, *b*, with inclined blades, placed in each column; the scrapers, *d*, mounted on the same axes as the stirring blades, scrape the false bottom, *c*. The exhausted material is evacuated through

the outlet, *g*. If desired, the material to be treated may be introduced at the upper part of the vessel and evacuated below, the solvent then being introduced at the lower part and the juice withdrawn above.—L. E.

Sugar syrups; Process and apparatus for direct conversion of — into sugars ready for consumption and of pleasant flavour. C. Grière. Fr. Pat. 402,305, Apr. 22, 1909. Under Int. Conv., Apr. 23, 1908.

A SUGAR solution, preferably of high purity, is rapidly evaporated, at first in a vacuum and then in air, the solution being protected from the air by a stratum of vapour. Evaporation is continued until a temperature of 120°—130° C. is attained. The brief action of a high temperature (about 125° C.) imparts a flavour to beet sugar similar to that of cane sugar; in the case of cane sugar the temperature should not be raised to so high a point. The syrup is now treated with a quantity (amounting to 50 or 100 per cent. of the syrup, or even more) of fine sugar, similar in quality to that of the product desired, in a malaxeur. The pasty crystalline mass thus obtained is transferred to a screw conveyor consisting of a closed vessel through which passes a shaft carrying a helix and stirring arms; the mass is submitted to the action of a current of cold air passing through the conveyor, and leaves the conveyor in the form of a powder which is subsequently sifted. Instead of adding sugar to the evaporated solution, the latter may be further evaporated in a vacuum, or successively in a vacuum and in air; or again, a small quantity of sugar may be added to the evaporated solution, the mixture then being submitted to the action of a partial vacuum.

—L. E.

Milk-sugar [lucose] from whey; Process of extracting — J. A. R. Nilsson and S. A. Hellqvist, Björketorp, Sweden. U.S. Pat. 938,017, Oct. 26, 1909.

AFTER separating the greater part of the albuminous substances by precipitation and filtration, the whey is concentrated to a sp. gr. of about 1.11. The solution is again treated with a precipitant and filtered to remove the remainder of albuminous substances and other impurities, and then concentrated until crystallisation begins, the refined lactose being finally extracted.—L. E.

Starch; Manufacture of soluble — Administration des Mines de Bouxwiller. Fr. Pat. 402,060, April 15, 1909.

SEE Eng. Pat. 9370 of 1909; this J., 1909, 950.—T. F. B.

XVII.—BREWING, WINES, SPIRITS, &c.

Beers; The quantity of sulphurous acid in non-sulphited — Bonn. Ann. des Falsific., 1909, 2, 44—45.

IN view of the fact that, by a decree dated July 28, 1908, the sale of beer containing more than 50 mgrms. of sulphur dioxide is prohibited in France, the author has examined a number of samples of beer to which neither sulphurous acid nor sulphites had been added, in order to ascertain what quantities, if any, of sulphurous acid exist normally in such beers. Fifteen samples were analysed and the amount of sulphur dioxide found varied from 12.8 to 25.6 mgrms. per litre. This sulphur dioxide was evidently derived from the raw materials, and the question is raised whether these figures should not be taken into account in calculating the quantity of the preservative actually added to a beer.—W. P. S.

Wines of Loire-Inferieure; Free tartaric acid in — A. and P. Audonard. Ann. des Falsific., 1909, 2, 267—274.

IN 1906 and 1907 the proportion of free tartaric acid in certain wines from Loire-Inferieure exceeded 1 gm. per litre, and in the wine of Gros-Plant grapes, reached 3 to 4 grms. per litre. Since the same kind of vine produces, in the same year, in different places, grapes containing different amounts of free tartaric acid, it is probable that the degree of maturity of the fruit has some influence upon the acidity, although this factor is not of very great importance. Any correlation between the excess of free tartaric acid and exhaustion of the soil of potassium is excluded by the fact that the soil of Loire-Inferieure is particularly rich in that element. With regard to the possibility of the later ripening of the vine Gros-Plant compared with Muscatel, and the consequent exposure of the fruit to lower temperatures being the cause, it is pointed out that other vines (e.g., Gros-Lot and Cinq-Mars) also ripen later than Muscatel vines, but that their grapes do not contain a larger proportion of free tartaric acid. The chief factor appears to be inherent in the nature of the vine. In any case, the authors' results show the risk of relying upon calculations based upon the excess of free tartaric acid as evidence of the watering of a wine, without knowing more of its origin. In the author's opinion the composition of the principal wines of all the wine-producing districts ought to be determined every year, so as to obtain values upon which commercial transactions might be based.—C. A. M.

Kirsch liqueurs; Nature of the cyanogen compounds contained in — X. Roques and L. Lévy. Ann. des Falsific., 1909, 2, 196—200.

IN order to ascertain in what form hydrocyanic acid exists in Kirsch liqueurs, the authors made a number of comparative distillations of both old and new liqueurs and of a solution of hydrocyanic acid in 50 per cent. alcohol. A litre of each was distilled and nine fractions of 100 c.c. were collected in each case, the hydrocyanic acid in them being then determined by titration with $N/20$

solution of silver nitrate in the presence of potassium iodide and ammonia. The samples were also saponified with sodium hydroxide and then subjected to similar distillation after acidifying with phosphoric acid. On direct distillation, two freshly-prepared samples of Kirsch liqueur yielded quantities of hydrocyanic acid corresponding with 15.95 and 22.0 c.c. of $N/20$ silver nitrate, respectively, whilst samples which were several years old, yielded quantities of hydrocyanic acid requiring from 6.80 to 17.25 c.c. After saponification, the distillates contained slightly more hydrocyanic acid, the increase varying from 0.05 to 2.75, as expressed in c.c. of the silver nitrate solution. The rate of distillation of the hydrocyanic acid, as shown by the quantities of the latter in the fractions, was different, both in the case of old and new liqueurs, from that of the alcoholic hydrocyanic acid solution, but after saponification, the rate was approximately the same in all three. The authors conclude that the hydrocyanic acid is present in the liqueurs partly in the free state and partly combined with fatty substances, as the latter were noticed in some of the distillates. The acid does not appear to be present as an ethyl ester.—W. P. S.

Treatment of plants with arsenic salts and the pure food supply. Porchet. See XVIII.4.

PATENTS.

Beer and other fermented liquors; Manufacture of — G. W. J. Allen, Bristol. Eng. Pat. 11,277, May 12, 1909.

THE beer, or other fermented liquor, is subjected, during fermentation, to the action of an electric current of high voltage (say 120,000) and low ampérage (say 24 or 25 millampères) derived from the secondary of an induction coil, provided with an interrupter or trembler. Fermentation can be stopped in this way at any desired period, and the alcoholic content, flavour, and quality, thus regulated.—L. E.

Alcohol; Process for combined denaturing and carburetting of — A. J. Durnpt. First Addition, dated Aug. 27, 1908, to Fr. Pat. 368,713, Aug. 8, 1906 (this J., 1907, 29).

THE following improved process is claimed:—Alcohol (of 95 per cent. concentration), methylvated to the extent of 2 or 10 per cent., is distilled with dehydrated coal tar oil. Part of the distillate is reserved, the remainder being mixed, in suitable proportions, with benzol (distilling between 81° and 102° C.), petroleum ether, and crude petroleum. A single distillate may be obtained from this mixture, consisting of a carburetted and denatured alcohol which does not congeal and which is suitable for motors. Again, the mixture may be fractionated into an alcohol B (carburetted to the extent of 45 per cent.) distilling below 77°—78° C., and an alcohol A (carburetted to the extent of 20 per cent.) distilling from 77°—78° to 80°—81° C. These two fractions constitute about two-thirds and one-third respectively, of the whole distillate. The freezing point of alcohol B may be lowered by adding to 100 volumes, 25 volumes of the reserved part of the first distillate, in the cold; this operation reduces the degree of carburetting to 36 per cent. The alcohol A may be used for various purposes, such as denaturation, illumination, heating.—L. E.

Musts; Apparatus for continuous desulphitation and concentration of — J. Sicard and F. P. Vidal. Fr. Pat. 402,328, Apr. 23, 1909.

THE must passes from a constant level reservoir to a regenerator, and thence through a pipe from which it is discharged into the centre of a large dish; the exit of this pipe is provided with a cock which is governed by a float, whereby the level of the liquid in the dish is kept constant. The dish is provided with a helicoidal partition and the passage formed by the latter contains a worm with an inlet at the periphery and an outlet at the centre of the dish. Vapour is passed through this worm from a boiler; its return to the boiler is insured by the elevated position of the dish. The must passes

from the centre of the dish through the passage formed by the partition and undergoes desulphitation; if the rate of circulation is slow, the must becomes concentrated. The must is evacuated through a pipe at the periphery of the dish and passes to a cooling worm contained in the above-mentioned regenerator.—L. E.

Alcoholic liquors; Process and apparatus for maturing and purifying —. A. Haack, Jonzac, France. Eng. Pats. 5790, March 10, 1909, Under Int. Conv., March 11, 1908, and 6397, March 17, 1909, Under Int. Conv., March 21, 1908.

XVIII.—FOODS; SANITATION; WATER PURIFICATION, & DISINFECTANTS.

(A.)—FOODS.

Casein in milk; Rapid method of determining —. T. B. Robertson. J. Ind. and Eng. Chem., 1909, 1, 723—725.

THE author has previously shown that the percentage of casein in a solution can be determined by aid of the formula: $c = \frac{n - n_1}{0.00152}$, where c is the percentage of casein,

n is the refractive index of the solution, and n_1 is a constant which depends upon the concentration and nature of the alkaline (or acid) solution used as solvent, being 1.33444 for N/10 sodium hydroxide solution at 20° C. The method may be applied to the determination of casein in milk. 50 c.c. of the sample are diluted to 250 c.c., and 75 c.c. of N/10 acetic acid are added slowly, with continuous stirring. After washing the precipitate by decantation, it is collected on a 15 cm. S. and S. No. 589 "white band" paper, and after draining for 1 hour, the paper and precipitate are macerated in 100 c.c. of N/10 sodium hydroxide until the paper is converted into a fine pulp and the casein completely dissolved. The solution is then filtered, and the refractive index of the filtrate determined at 20° C. with a Pulfrich refractometer. The number of grams of casein in the 50 c.c. of milk is calculated from the formula, $n - 1.33444 - \frac{0.00152}{c}$, where n is the refractive index of the solution.

In order to overcome the slight error due to the water associated with the filter and precipitate, the final solution, before filtration, may be diluted to an accurately measured volume with N/10 sodium hydroxide. If the refractive index be determined at temperatures between 10° and 20° C., 0.00007 must be added to the value of the constant n_1 (1.33444) for every degree by which the temperature is less than 20° C., whilst for temperatures between 20° and 30° C., 0.001 must be subtracted for every degree above 20° C.—A. S.

Milk; Preservatives in —. Times, Nov. 10, 1909. [T.R.]

THE National Pure Food Association recently agreed to a resolution regretting the decision of the Local Government Board to allow an increased amount of boric acid in milk during the summer months. In reply the Local Government Board states that it neither allows nor

encourages the use of any boric acid in milk, and have not come to any such decision as that referred to in the resolution of the Association.

Butter; Quantity of water in — from Northern France. L. Vuallart. Ann. des Falsific., 1909, 2, 41—44.

THE author has determined the quantity of water in 111 samples of butter obtained from farmers and factories in some of the Northern Departments of France. Eighty-six of these samples contained less than 15 per cent. of water; eleven contained from 15 to 16 per cent.; ten from 16 to 18 per cent.; two from 18 to 19 per cent.; and the remaining two samples contained 20.5 and 23.3 per cent., respectively. The two latter samples exhibited a watery appearance when cut, but had not the pasty, emulsified consistence of butters intentionally mixed with an excess of water. The undue proportion of water in the butters was apparently due to careless or negligent working.—W. P. S.

Flour bleaching, its relation to bread production and nutrition. J. A. Wesener and G. L. Teller. J. Ind. and Eng. Chem., 1909, 1, 700—711.

A DISCUSSION of the question of the effect of bleaching on the quality of flour, in which the authors bring forward evidence against the view that bleaching is detrimental (compare Ladd, this J., 1909, 377). Their conclusion is that the effect of bleaching, when properly carried out, is to destroy a small amount of yellow colouring matter, which in itself is of no value as a food material. It is further claimed that bleaching tends to make more pronounced any defects in the flour, and that commercially bleached flours do not contain any substance that, in the minute quantities in which it is present, has in any way an injurious effect on the bread-making qualities of the flour, or is in any way poisonous, or has any toxicological or preservative action, or any action which is prejudicial to digestion or nutrition. (See also this J., 1906, 194; 1908, 136; 1909, 669, 737.)—A. S.

Soya beans; Cultivation and uses of —. E. S. Edie. Liverpool University Inst. of Commercial Research in the Tropics, Bull. No. 1, Vol. 1, 1909.

IN the Southern States of N. America the soya plant is grown for fodder, for it has been found that with an addition thereof to their food, cows give a greater yield of milk of better quality. In Japan a liquid resembling cows' milk is prepared from soya beans, and when condensed *in vacuo*, after the addition of cane sugar and potassium phosphate, gives a product resembling condensed milk. This preparation has considerable nutritive value, but is unsuitable for children. The bean meal is made into biscuits, and in some parts of Europe is now used instead of rye meal for bread. In England it is used in admixture with flour in making brown bread. Experiments carried out at Cirencester showed that the butter from cows fed upon soya bean cake had not quite so good a flavour as that from cows fed upon decorticated cotton cake, but that the yield of butter from the milk and percentage of butter fat were slightly higher. The general conclusion was that for winter feeding soya beans would be the better food. In the East, and especially on sugar plantations in Southern China, the oil cake is used as a fertiliser. As yet, the cultivation of soya beans is restricted to the Far East, and to some of the N. American States. It could probably be successfully grown in most of the British African Colonies. The most favourable soil is a medium one fairly rich in phosphoric acid, potassium and calcium, and on good land the yield may reach 100 bushels of seed and 9 to 12 tons of fresh fodder per acre. Where the beans are the chief object the best method is to grow the plant between rows of maize or other crops. There are over 20 varieties of soya beans (see Bull. No. 98, Bureau Plant Ind., U.S. Dept. Agriculture), but the chief variety known in Europe is yellow and resembles a pea in appearance. Three grades of these beans are imported, which are shipped at: (1), Dalny; (2), Vladivostok; and (3),

Hankow, respectively. Analyses of 5 distinct varieties used as food by the Chinese in Liverpool were made by the author with the following results:—

Sample.	Moisture.	Ash.	Oil.	Albumi- noids.	Carbo- hydrates.	Woody fibre.
	per cent.	per cent.	per cent.	per cent.	per cent.	per cent.
1	11.17	4.36	16.76	39.75	22.30	—
2	9.91	5.31	16.45	40.46	21.45	5.80
3	10.62	4.51	18.11	37.07	24.46	5.23
4	—	—	—	35.42	24.58	—

A sample of the beans grown in W. Africa from seed sent out this year gave the following results:—Moisture, 10.52; ash, 4.62; oil, 17.26; albuminoids, 36.05; carbohydrates, 26.16; and woody fibre, 5.39 per cent. These figures indicate that, in the first season, at all events, the soya bean did not deteriorate in W. Africa. The plants also matured rapidly.—C. A. M.

Alimentary products; The colouring of —. Colours allowed to be used in France. F. Muttetlet. Ann. des Falsific. 1909, 2, 26—38; 243—251.

By a decree issued by the French Minister of the Interior and dated August 4, 1908, certain dyestuffs may be employed for colouring articles of food, beverages, etc. These colours are as follows:—Eosine (tetrabromofluoresceine); Erythrosine (methyl and ethyl derivatives of Eosine); Bengal-phloxine Rose (iodine and bromine derivatives of chlorinated Fluoresceine); Bordeaux-ponceau Reds (prepared by the action of sulphonic derivatives of naphthol on diazoxylenes); Acid Yellow, Golden Yellow (sulphonic derivatives of naphthol); Acid Magenta (free from arsenic and prepared by Couper's process); Lyons Blue, Light Blue, Couper Blue (derivatives of triphenylrosaniline or of diphenylamine); Malachite Green (tetramethyldiaminotriphenylcarbinol hydrochloride); greens made of mixtures of the above-mentioned blues and yellows; Paris Violet (penta- and hexa-methyl-pararosanine hydrochlorides); and Methylaniline Violet. The author considers that other dyestuffs might be admitted as coming under the above nomenclature, and suggests that the list might be enlarged so as to also include:—Rhodamine B (diethylmetaminophenolphthalein); Bordeaux S (naphthionic-azo- β -naphtholdisulphonic acid R); New Cocaine (naphthionic-azo- β -naphtholdisulphonic acid G); Solid Red E (naphthionic-azo- β -naphtholmonosulphonic acid S); Bordeaux G (aminoazotoluenesulpho-azo- β -naphtholmonosulphonic acid S); Ponceau 2R (metaxylidine-azo- β -naphtholdisulphonic acid R); Xylidine Scarlet (xylidine-azo- β -naphtholmonosulphonic acid S); Acid Magenta (magenta-trisulphonic acid); Magenta (rosaniline and para-rosaniline hydrochlorides); Orange I (sulphanilic-azo- α -naphthol); Naphthol Yellow S (dinitro- α -naphtholsulphonic acid); Chrysoine (sulphanilic-azo-resorcinol); Auramine O (diminotetramethyldiaminodiphenylmethane hydrochloride); Acid Green (diethyldibenzylaminotriphenylcarbinoltrisulphonic acid); Patent Blue (meta-hydroxytetra-ethyl-diaminotriphenylcarbinoldisulphonic acid); and Couper's Blacks (sulphonated indolines and nigrosines). The use of Martins Yellow (dinitro- α -naphthol) and a Malachite Green (tetramethyldiaminotriphenylcarbinol picrate) is not permitted.—W. P. S.

Arsenic salts; Treatment of plants with —, and the pure food supply. F. Porchet. Agrik.-Chem. Sektion des Schweiz. Ver. anal. Chem., Sept., 1909. Chem.-Zeit., 1909, 33, 1128—1129.

The use of salts of arsenic in solution as insecticides for fruit trees and vines is widespread, and the question arises whether the quantity of arsenic used is sufficient to harm the health of the consumer of the fruit, etc. Experiments were made on pear trees with and without treatment with lead arsenate, also examinations of fruit juices from plants treated with Schweinfurt green. The analyses were made by the Marsh-Strzyzowski method (Oesterr. Chem.-Zeit., 1904, [4]). It was found that traces

of arsenic are naturally present in the fruits, wines, and especially in the wine-lees, but that these are noticeably increased by treatment of the trees with arsenic compounds. The amounts found were 0.2—0.3 mgrm. per kilo. of fruit, mostly in the juice. In the case of the grape, the must contained only very small traces of arsenic, from nil up to 0.1 mgrm. per litre, whilst the lees contained 3—20 mgrms. of arsenic trioxide per kilo. There is no danger to health therefore in the use of the arsenic treatment process.—J. H. J.

Adulteration of edible oil with mineral oil. Roumet. See XVIII.A.

PATENTS.

Substances, animal and vegetable; Process of preserving — [by means of liquid nitrogen]. E. Cadoret. Fr. Pat. 402,623, Sept. 2, 1908.

ANIMAL or vegetable substances are preserved by treating them, in any suitable way, with liquid nitrogen either concentrated or diluted.—W. P. S.

Alimentary substance consisting chiefly of glutamic acid; Method of manufacturing an —. K. Ikeda and S. Suzuki. Fr. Pat. 402,630, May 1, 1909.

ALBUMINOUS substances, preferably of vegetable origin, are digested with an excess of either hydrochloric acid or sulphuric acid, to which may be added metallic iron or tin, sulphurous acid, etc., in order to increase the hydrolytic action. The acid used is then removed as far as possible, the solution is neutralised by the addition of sodium hydroxide, and evaporated to a syrupy consistence, or to dryness. The neutralised solution may also be subjected to electrolysis, the anode used being made of iron, aluminium, or zinc. A glutamate of these metals is thus obtained which may be afterwards converted into the sodium salt. This treatment is useful in order to remove objectionable odours and foreign substances from the product.—W. P. S.

Wheat flour; Milling and conditioning —. H. Simon, Ltd. Fr. Pat. 402,755, May 6, 1909. Under Int. Conv., May 7, 1908.

SEE Eng. Pat. 9946 of 1908; this J., 1909, 1059.—T. F. B.

(B.)—SANITATION; WATER PURIFICATION.

PATENTS.

Waters; Purification of potable — [neutralisation of acidity]. F. Candy, London. Eng. Pat. 24,430, Nov. 13, 1908.

THE object of the invention is to neutralise the acidity of moorland and upland waters in order to prevent the solvent action of these waters on lead pipes. For this purpose the water is passed through a bed or layer consisting of fragments of magnesium oxide, or a mixture of the latter with ordinary filtering material. It is preferable to filter the water through an ordinary filter-bed before passing it through the magnesium oxide layer. The magnesium oxide is obtained by thoroughly igniting magnesite, and the size of the fragments used and the depth of the layer will depend on the acidity of the water, the rate of flow, and the hardness, if any, that it is desired to impart to the water.—W. P. S.

Water; Purification of —. F. Candy, London. Eng. Pat. 4212, Feb. 20, 1909.

THE free or available chlorine remaining in water that has been treated with chlorine or substances containing available chlorine, is removed by passing the water through a bed or layer of fragments of coke, or other carbonaceous matter, or by agitating the water with powdered coke or other powdered carbonaceous material, and then removing the particles of dechlorinating agent by filtration or deposition.—L. E.

Water; Process of preparing potable — J. T. Harris, New York. U.S. Pat. 937,210, Oct. 19, 1909.

THE water is subjected to electrolysis in the presence of iron and aluminium hydroxides and a compound of copper. The anodes employed consist of iron and aluminium, whilst the cathode is made of copper.—W. P. S.

Water and other liquids; Apparatus for purifying — E. Gobbi. Second Addition, dated April 19, 1909, to Fr. Pat. 359,128, Jan. 11, 1905.

RIDGES or projections are provided on one of the surfaces of the plates employed in the filtering apparatus described in the main patent (see Eng. Pat. 83 of 1906; this J., 1906, 802); interstices of any desired section are thus produced between the plates.—W. P. S.

Trade effluents; Process and apparatus for purifying — by decantation. V. Antoine. First Addition, dated April 2, 1909, to Fr. Pat. 374,040, Jan. 29, 1907 (this J., 1907, 775).

MODIFICATIONS in the apparatus described in the original patent (*loc. cit.*) are given. The stem of the funnel through which the water is introduced increases in diameter as it descends towards the bottom of the conical tank and a pipe, gradually decreasing in diameter, passes down the centre of the stem of the funnel and ends just above the sludge outlet. A short, cone-shaped device may be fitted concentrically at the bottom of the tank in order to aid in the separation of the suspended matters, this object being also facilitated by the shape of the funnel-stem. Other forms of the apparatus are described, in one of which the inlet funnel carrying the aluminium sulphate is placed outside the tank, the stem of the funnel entering the side of the tank towards the bottom of the latter.—W. P. S.

Sewage; trade effluents, etc.; Process for the automatic sterilisation of — F. Duret. Fr. Pat. 402,005, April 14, 1909.

THE sewage or other liquid is conducted into the bottom of a closed chamber where it is subjected to anaerobic fermentation. It then passes from the top of this chamber to the bottom of a second chamber to which air is admitted, and thence to a third chamber containing a siphon and a ball-float which operates an automatic device for the introduction of the sterilising agent. The siphon delivers the treated liquid into a series of mixing chambers, pipes connecting the bottom of one chamber with the top of the next, and so on. Trade effluents need not be subjected to the preliminary anaerobic and aerobic fermentation, and the composition of the sterilising agent may be altered as desired.—W. P. S.

Filters; Process and apparatus for cleansing — A. Endler. Fr. Pat. 402,277, April 21, 1909.

THE process relates to the cleansing of solid filters made of porous porcelain, clay, etc., such as the Berkefeld filter-cylinders, and for this purpose the jacket surrounding the filter-cylinder is partially filled with granular material. The jacket is provided with a double bottom so that compressed air may be admitted to the jacket. This air agitates the granular matter and causes the removal of the solid substances adhering to the sides of the cylinder. Compressed air may also be admitted to the interior of the cylinders. Where several of the filter cylinders are fitted in one outer vessel, each cylinder may be enclosed in a separate jacket which is partially filled with the granular matter, the necessary compressed air pipes being fitted to each.—W. P. S.

Water; Compound for purifying — C. W. Schultze, Assignor to The Clarine Co., Buffalo, N.Y. U.S. Pat. 935,695, Oct. 5, 1909.

See Fr. Pat. 400,525 of 1909; this J., 1909, 1060.—W. P. S.

Water-purifying apparatus. H. Reisert, Cologne, Germany. U.S. Pat. 938,075, Oct. 26, 1909.

SEE Eng. Pat. 18,355 of 1908; this J., 1909, 957.—T. F. B.

Gas-producer for destruction of refuse, etc. Fr. Pat. 401,859. See 11.

(C.)—DISINFECTANTS.

Bordeaux spraying. S. U. Pickering. J. Agric. Science, 1909, 3, 171—178.

THE author has pointed out previously (this J., 1907, 1291) that the fungicidal action of Bordeaux mixture is due to the normal copper sulphate formed by the action of carbon dioxide on the basic sulphate, and hence that the mixture (Woburn Bordeaux) produced by adding only sufficient lime to precipitate all the copper, and containing the substance, $4\text{CuO} \cdot \text{SO}_3$, should be $2\frac{1}{2}$ times as effective as ordinary Bordeaux mixture obtained with equal parts of lime and copper sulphate, and containing the compound, $10\text{CuO} \cdot \text{SO}_3$, with excess of lime. Direct determinations of the copper sulphate recoverable by the action of carbon dioxide prove the existence of secondary reactions, which greatly increase the relative efficacy of the Woburn mixture. With Woburn Bordeaux, 25 per cent. of copper sulphate was produced in two hours, and a total of 40 per cent. was reached in two days. With ordinary Bordeaux, in one experiment 3.7, and in another 2.7 per cent. was produced, and this only after a delay of from 2 to 24 hours. Hence it results that $\frac{1}{4}$ lb. of copper sulphate per 100 gallons, in the form of Woburn Bordeaux, would be as efficient as 16 lb. in the form of the ordinary Bordeaux. Dried Bordeaux, though largely used as a labour-saving substitute, is much inferior to the Woburn Bordeaux; less than 4 per cent. of the copper sulphate being recoverable, or a little more than in the ordinary mixture. In practical spraying, the efficiency of the dried Bordeaux is generally regarded as somewhat less than that of the ordinary mixture. The addition of treacle to Bordeaux mixtures has been advocated as a means of getting part of the copper into solution before use, and also for increasing the adhesion to the leaves. Experiments show an increase in the amount of copper rendered soluble, and a quickening of the action; the author questions whether this acceleration of action would be beneficial. Moreover, with ordinary Bordeaux and treacle, decomposition takes place, with precipitation of cuprous oxide, thus robbing the mixture of its soluble copper. A mixture of copper sulphate and sodium carbonate, known as "Soda Bordeaux," has been suggested as a substitute for ordinary Bordeaux, but it cannot be regarded as an efficient fungicide, and reports as to its action seem generally to be unfavourable.

—R. C. P.

Sulphur in alkali polysulphides; Determination of — C. Dusserre and V. Vuilleumier. Agrik.-chem. Sektion des Schweiz. Ver. anal. Chem., Sept., 1909. Chem.-Zeit., 1909, 33, 1129.

THE use of alkali polysulphides in the treatment of vine disease is extending. Their market value depends upon their content of sulphur as polysulphide, which does not lend itself to easy estimation. The authors have worked out a new method: 10 grms. of the substance are dissolved in 500 c.c. of water and the solution filtered; 5 c.c. of this solution are placed in a flask with 30—40 c.c. of concentrated ammonia and diluted with an equal bulk of water. On gradually heating to boiling and adding $N/10$ silver nitrate drop by drop, a colloidal solution is formed and the liquid remains transparent. On addition of more silver nitrate and stirring the boiling solution, a black precipitate is suddenly formed and the supernatant liquid becomes colourless. The number of c.c. of silver nitrate used multiplied by 1.6 gives the percentage of sulphur as polysulphide in the sample. Figures are quoted showing the close agreement between this process and the more exact but longer cadmium process on polysulphides from various sources.—J. H. J.

Tobacco-juices; Determination of nicotine in concentrated — F. Porehet and F. Régis. Agrik.-chem. Sektion des Schweiz. Ver. anal. Chem., Sept., 1909. Chem.-Zeit., 1909, 33, 1128.

THE methods of Schloesing (ether extraction), Biel (steam extraction), and Toth (absorption of ammonia and

separation by a mixture of ether and petroleum spirit) for the estimation of the nicotine in tobacco-juice were compared as to their suitability for use in the valuation of juices used as insecticides in vineyards. Schloesing's method gave much lower values than the other two, but these also varied slightly according to the nature of the juices. In duplicate analyses of the same samples containing from 4–10 per cent. of nicotine, the greatest difference was 1 per cent. with Bied's method and 0.8 per cent. with Toth's. The latter method is recommended as being quickly carried out and sufficiently accurate for technical purposes.—J. H. J.

Treatment of plants with arsenic salts and the pure food supply. Porchet. See XVIII. A.

PATENTS.

Product for the treatment of cryptogamous diseases of plants and especially of mildew, and process of manufacturing the same. "Cuprosa," Soc. Anon. Suisse pour la Production du Sulfate de Cuivre. First Addition, dated April 22, 1909, to Fr. Pat. 375,849, Mar. 18, 1907 (this J., 1907, 987).

OXYCHLORIDE of copper is intimately mixed with sulphur or inert material, such as powdered talc, plaster, etc., and the mixture, which should contain not less than 5 per cent. of copper, is applied to plants in the dry state by the usual means.—F. SOBX.

Cerium compounds of phenols; Process for preparing —. Chem. Fabr. auf Actien, vorm. E. Schering. Ger. Pat. 214,782, Feb. 21, 1907.

COMPOUNDS of cerium with phenols and their derivatives are produced by the action of cerium salts on the phenols, e.g. in presence of alkali. The preparation of the compounds of phenol, guaiacol, tri-iodo-*m*-cresol, and β -naphthol are described. The products are stated to possess powerful disinfectant properties, and to be less irritating and less poisonous than the phenols themselves.—T. F. B.

XIX.—PAPER, PASTEBOARD, &c.

Viscose; Improvement in the preparation of —. F. Todtenhaupt. Chem.-Zeit., 1909, 33, 1149.

THE author notes that little variation of the originally patented process of making viscose (Eng. Pat. 8700 of 1892) has resulted from later experiences. Steam (Eng. Pat. 7023 of 1903) closely follows the details set forth in the original patent. These conditions are: 100 parts of cellulose are treated with a 17.7 per cent. solution of caustic soda for 24 hours, the excess of soda removed by pressing until the total weight is three times the original, and after keeping in a closed vessel for 48 hours, 75 parts of carbon bisulphide are added, and the mixture stirred for 5 hours. The product thus obtained after the spontaneous evaporation of the excess of carbon bisulphide, is dissolved in water. According to the author, lumps of alkali-cellulose are not acted upon by the carbon bisulphide, owing to the "balling" of the former, and to prevent this, he suggests the use of a non-reacting solvent, e.g., petroleum spirit or carbon tetrachloride, the time of reaction being extended proportionately according to the ratio of carbon bisulphide to the solvent. In this way, it is stated, the coagulation of the cellulose xanthogenate is prevented, and the viscose is obtained as open loose masses from which the excess liquid can easily be recovered by pressing.—W. N. B.

PATENTS.

Alcohol; Process for obtaining — from the waste liquors of the manufacture of wood pulp by soluble sulphites. Stora Kopparbergs Bergslags Aktiebolag. Fr. Pat. 402,331, April 23, 1909. Under Int. Conv., May 9 and Oct. 7, 1908.

THE lime mud (which, besides calcium carbonate, contains organic matters and salts of sodium and magnesium)

obtained as a waste product in the treatment of the waste liquors with sodium sulphate or carbonate, is used to neutralise the waste liquor which contains, in addition to glucose and other organic substances, a small quantity of calcium bisulphite and free sulphurous acid. Not only is neutralisation thus effected, but the liquor is also enriched with nutritive substances necessary for the subsequent fermentation. If necessary, the liquor is rendered neutral, or slightly acid, by addition of acid or alkali, and is then separated from the precipitate. The liquor is then cooled, preferably by being sprayed downwards from the top of a tower and encountering a current of air moving upwards; by this treatment, it is also concentrated and saturated with air. It is then treated with an enzyme preparation or with yeast, and with nutrient yeast extract, the alcohol formed being separated by distillation or otherwise.—L. E.

Celluloid-like substance; Process for the preparation of a — which burns with difficulty. B. G. Buchstab, Ger. Pat. 214,398, July 23, 1908.

AIR or oxygen is blown through a solution of gun-cotton, the evaporated solvent being replaced by methyl alcohol or other suitable solvent. The product thus obtained is then worked up into celluloid with the addition of lactic acid or its salts, or strontium chloride, in place of camphor, and a small proportion of castor oil.—A. S.

Cellulose compounds in shapes; Process for making —. L. Lederer. Fr. Pat. 402,072, April 15, 1909. Under Int. Conv., July 3, 1908.

SEE Eng. Pat. 11,625 of 1909; this J., 1909, 1030.—T. F. B.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENTIAL OILS, & EXTRACTS.

Belladonna berries; Amount of alkaloid in —. J. H. Williams. Pharm. J., 1909, 83, 493.

THE amount of total alkaloids in the fruit of *Atropa belladonna* varies from 0.107 to 0.132 per cent., in both ripe and unripe berries.—J. O. B.

Elaterium; Chemical examination of —, and the characters of elaterin. F. B. Power and C. W. Moore. Pharm. J., 1909, 83, 501–504.

AN examination was made of the best English elaterium. After distilling with steam, the portion insoluble in water was extracted with chloroform and alcohol. The extracts obtained with these solvents were extracted with light petroleum and ether. The ether extract consisted chiefly of a colourless crystalline product, which corresponded in its properties to the "elaterin" of the Pharmacopœias. It melted at 217°–220° C. and had $[\alpha]_D = -16.4^\circ$. By fractional crystallisation this product was found to contain 60 per cent. of a substance, which had practically no purgative action, melted at 230° C., and had $[\alpha]_D = -52.9^\circ$. Smaller fractions were obtained, which together had $[\alpha]_D = +13.9^\circ$, and showed a high degree of physiological activity. Commercial samples of English and German "elaterin" yielded similar results on examination. The purgative action of elaterin appears to depend upon the amount of dextro-rotatory substance present.—F. SHDN.

Clove oil; Alcoholic constituents of —. H. Masson. Comptes rend., 1909, 149, 630–632.

ON examining that fraction of a clove oil which passed over below 125° C. at 10 mm. pressure, the author was able to identify methylamylcarbinol, methylheptylcarbinol, and benzyl alcohol. The presence of methylfurfural in the higher-boiling portion of the fraction was also indicated, but absolute identification was not obtained.—J. A.

Carrot oil. E. Richter. Arch. Pharm., 1909, 247, 401—413.

THE author has found the following substances in carrot oil. It contains 0.01 per cent. of free isobutyric acid, and 0.80 per cent. of free palmitic acid; 7—9 per cent. of esters are present, acetic acid being found in this form; *d*-pinene and *l*-limonene were found to the extent of 14 per cent. After fractionation in a vacuum, a crystalline alcohol, $C_{17}H_{34}O$, styled *dancol*, was obtained, which melts at $115-116^{\circ}C$. A satisfactory method of purifying this alcohol was to convert it into the sodium salt of a xanthogenic acid, and liberate the alcohol from this compound. A large proportion of the oil consists of high-boiling sesquiterpenes, with high densities. When distilled at 24 mm. three fractions were obtained, boiling at $135-146^{\circ}$, $149-153^{\circ}$, and $156-164^{\circ}C$. respectively.

—F. SODN.

Ethyl ether. Part I. Influence of water and alcohol on its boiling-point. J. Wade and H. Finnmere. Chem. Soc. Proc., 1909, 25, 236—237.

ETHER as usually purified is not homogeneous, and is resolvable into two physical constituents by accurate fractionation. The more volatile constituent contains water that has escaped the ordinary drying agents, and under suitable conditions may be isolated as a binary mixture of ether and water, having a constant and minimum boiling-point, 34.15° (corr.), and containing about 1.3 per cent. of water. At the ordinary temperature this binary mixture is practically a saturated solution of water in ether; it has been found incidentally that the solubility of water is approximately constant at 0.013 gram per gram of ether between 20° and 15° , and then decreases to 0.009 gram per gram at 10° , the lowest temperature employed. The less volatile constituent obtained on fractionating ordinary ether is approximately pure ether, b. pt. 34.50° (corr.). In presence of alcohol the boiling point may be appreciably raised, by an amount varying with the proportion of alcohol in the still; the highest observed was 34.73° (corr.). There is no evidence, however, of the formation of a mixture of constant boiling point, for although a very appreciable amount of alcohol passes over with the ether, this may be gradually eliminated by repeated fractionation. Alcohol has a similar influence on the boiling point of the binary aqueous mixture, and when ether containing both water and alcohol is fractionated, indications of a third physical constituent are sometimes obtained. This, however, is not due to the formation of a binary mixture of ether and alcohol, nor to that of a ternary mixture of all three substances, but is probably caused by the elevation in the boiling point of the binary aqueous mixture as the concentration of the alcohol increases. The mutually opposing influences of water and alcohol on the boiling point of ether render constancy of its boiling point as determined in the ordinary manner useless as a criterion of purity.

Ethyl acetate; Preparation of —. J. Habermann and H. Brezina. J. prakt. Chem., 1909, 80, 349—354.

WHEN a mixture of alcohol, acetic acid, and anhydrous copper sulphate is heated for many hours on the water-bath, fractionation of the product, dried with anhydrous magnesium sulphate, is found to give, besides unused alcohol and acetic acid, a liquid boiling at $70^{\circ}-72^{\circ}C$. A small proportion of a similar liquid is obtained by the systematic fractionation of commercial ethyl acetate, and in both cases, after treatment with calcium chloride and redistillation, pure ethyl acetate is obtained. The liquid boiling at $70^{\circ}-72^{\circ}C$. is apparently a compound of ethyl acetate and alcohol in molecular proportions.

—F. SODN.

Formic acid; Determination of —. H. Franzen and G. Greve. J. prakt. Chem., 1909, 80, 368—389.

THE authors have modified the method of determining formic acid by means of mercuric chloride, so as to make it applicable to solutions of widely varying concentration;

at the same time the quantity of mercuric chloride necessary has been reduced and the rapidity of the method considerably increased. Where it is not possible to carry out the determination directly on the solution to be examined, accurate results may be obtained by first distilling the formic acid in a current of steam and in the presence of phosphoric acid, using the neutralised distillate for the estimation. This is carried out as follows:—To the solution, containing 0.2—1 gram. of formic acid, as a soluble salt, in 1 litre, are added 7.5—15 grms. of mercuric chloride, dissolved in 100—200 c.c. of hot water; the liquid is stirred and heated on the water-bath, until the precipitated mercurous chloride has settled, and then sodium hydroxide is added to the hot liquid, until a brownish precipitate of mercuric oxide becomes permanent. The liquid is again heated on the water-bath, and, after the precipitate has completely settled, the neutralising is repeated. The precipitate is once more made to settle by heating on the water-bath, and then 20 c.c. of strong hydrochloric acid are added and the heating continued for an hour. The whole process of reduction takes about 2½ hours. The precipitate is collected in a Gooch crucible, well washed with hot water, dried for 6—8 hours in the steam oven and then for several hours in a vacuum desiccator; its weight multiplied by the factor 0.097726 gives the corresponding weight of formic acid.—F. SODN.

PATENTS.

Organic compounds; Catalytic agent for fixing and liberating hydrogen in —. Chem. Fabr. auf Actien, vorm. E. Schering. Fr. Pat. 401,876, April 8, 1909. Under Int. Conv., April 18 and July 17, 1908.

PURE nickel, obtained by reduction of the nitrate, is inactive for the purpose of converting borneol into camphor; if, however, a small quantity of sodium carbonate be added to the nitrate before reduction, a very active product is obtained; a similar mixture is obtained by adding 0.17 per cent. of pure sodium oxide to the nickel; other bases or salts which are not readily reduced at a red heat may be used in place of sodium oxide. Further, if a small quantity of certain other metals is introduced into the nickel, the mixture will have a very powerful catalytic action. Mixtures of 6.7 per cent. of cobalt or copper with 93.3 per cent. of nickel may be used; they are obtained by the reduction of the mixed nitrates. The process is not confined to the use of nickel; other metals possessing catalytic action can be used with equal effect.—T. F. B.

Mercury derivatives of fatty acids or their anhydrides; Process of preparing salts of —. W. Schoeller and W. Schrauth. Ger. Pat. 213,371, Dec. 6, 1907. Addition to Ger. Pat. 208,634, July 11, 1907 (see this J., 1909, 543).

THE salts of malonic acid or monoalkylmalonic acids are condensed with mercuric oxide or mercuric salts in presence of alkalis, to form the salts of mercuri-fatty acids or their anhydrides described in the principal patent.—T. F. B.

p-Methoxysulcylaldehyde from resorcinolaldehyde; Process for preparing — by methylation with methyl halides or dimethyl sulphate. Kalle und Co. Ger. Pat. 214,153, April 28, 1908.

p-METHOXYSULCYLALDEHYDE is obtained in a state of purity, and in good yields, as a stable substance of m. pt. $41^{\circ}C$. (not $62^{\circ}-63^{\circ}$, as stated previously), and easily soluble in warm water, by methylation of resorcinolaldehyde by means of a methyl halide or methyl sulphate, excess of alkali being avoided.—T. F. B.

Formaldehyde, together with methyl alcohol and formic acid; Process for the preparation of — from methane or gaseous mixtures containing methane by oxidation with air or oxygen. Sauerstoff- und Stickstoff-Ind. Hausmann und Co. Ger. Pat. 214,155, Sept. 26, 1906.

THE claim is for the use of bark, bast, or the like, as contact substance in the production of formaldehyde, methyl

alcohol, and formic acid from methane by oxidation. It is stated that by use of bark, *e.g.*, tan bark, oxidation can be effected at 30°–50° C., whereas with granulated copper, a temperature of about 600° C. is necessary.—A. S.

α-Bromoisovaleric ester of cholesterol; Process for preparing the —. Chem. Werke vorm. Dr. H. Byk. Ger. Pat. 214,157, July 19, 1908.

THE *α*-bromoisovaleric ester of cholesterol is a tasteless substance, of m. pt. 132°–133° C., insoluble in water, sparingly soluble in cold alcohol, and readily soluble in benzene. It is prepared from cholesterol and *α*-bromoisovaleric acid by the usual methods for making esters.

—T. F. B.

Arsenic-albumin compound; Process for the preparation of an —. F. A. V. Klopfer. Ger. Pat. 214,717, July 10, 1908.

THE nuclein-free protein of wheat (glutenin+gliadin) mixed with alcohol, is treated with arsenic trichloride at the ordinary temperature. For example, 10 kilos. of a mixture of gliadin and glutenin are mixed with 10 kilos. of 99 per cent. alcohol, and a mixture of 3 kilos. of arsenic trichloride and 5 kilos. of 99 per cent. alcohol added, with continuous stirring. After shaking in a closed vessel for six hours, the alcohol is distilled off *in vacuo*, and the residue powdered, washed with 99 per cent. alcohol, and dried *in vacuo*. The product, which is of therapeutic value, is a brownish powder soluble in hot water and in sodium hydroxide solution, but insoluble in organic solvents and in dilute acids.—A. S.

Alkyl ethers; Process for preparing aromatic —. A. Gerber. Ger. Pat. 214,783, Aug. 1, 1908.

ALKYL ethers of compounds containing a phenolic hydroxyl group are obtained by the action of normal alkylsulphurous esters on the alkali or alkaline-earth salts of the hydroxy-compounds, in presence of organic solvents, preferably aliphatic alcohols. The process as applied to the preparation of *o*-cresol methyl ether and codeine from *o*-cresol and morphine respectively, is described in detail. The sulphurous esters are readily prepared by the action of sulphur chloride or thionyl chloride on the absolute alcohol.—T. F. B.

Extracts of purgative drugs; Process for the preparation of purified —. Knoll und Co. Ger. Pat. 214,895, Aug. 25, 1908.

THE alcoholic extract of the drug (*Cascara sagrada* bark, senna leaves, aloes, etc.) is concentrated *in vacuo*, treated with ether so long as a precipitate is produced, filtered, evaporated, and mixed with lactose or the like.—A. S.

Thorium; Process for the separation of — from cerite and ytterbia earths. A. Rosenheim, R. J. Meyer, and J. Koppel. Ger. Pat. 214,886, Oct. 25, 1908.

THE process depends upon the fact that from a strongly acid solution, thorium is completely precipitated by the addition of hydrofluosilicic acid or a soluble silicofluoride, whereas the elements of the cerite and ytterbia earths remain almost entirely in solution.—A. S.

Guaiacol-5-monosulphonic acid carbonate and its salts; Process for preparing —. F. Hoffmann-La Roche und Co. Ger. Pat. 215,050, April 12, 1908.

GUAIACOL carbonate is treated, without heating, with concentrated sulphuric acid until the product is soluble in water. On cooling the mixture with ice, guaiacol-5-sulphonic acid carbonate, $(\text{CH}_3\text{O}.\text{C}_6\text{H}_3.\text{SO}_3\text{H})_2.\text{O}_2\text{CO}$, separates out, and may be purified by washing with concentrated hydrochloric acid. It melts at 115°–117° C., with evolution of carbon dioxide, and can be converted into its salts by the usual methods.—T. F. B.

Sodium arylimides; Process for preparing —. Deutsche Gold- und Silber-Scheide-Anstalt vorm. Roessler. Ger. Pat. 215,339, Oct. 8, 1907.

COMPOUNDS of sodium with primary or secondary aromatic amines are readily produced by heating together metallic sodium and the amine, in presence of a heavy metal, oxide, or salt, possessing catalytic properties, *e.g.*, copper, nickel, or cobalt, or their oxides or salts. Heavy metals which tend to form alloys with sodium should not be used. By this process, sodium can be made to combine with aniline in presence of a catalyser at 140° C.—T. F. B.

Pharmaceutical compound [p-aminobenzoic acid isopropyl ester]; Manufacture of a new —. P. A. Newton. From Farbenfabr. vorm. F. Bayer und Co., Elberfeld, Germany. Eng. Pat. 4321, Feb. 22, 1909.

SEE Ger. Pat. 211,801 of 1908; this J., 1909, 854.—T. F. B.

Aminoarylsulfinic acid; Derivatives of —. P. Ehrlich and A. Berthelm, Frankfurt, Assignors to Farbwerke vorm. Meister, Lucius, und Brüning, Höchst on Maine, Germany. U.S. Pat. 937,929, Oct. 26, 1909.

SEE Fr. Pat. 392,857 of 1908; this J., 1909, 107.—T. F. B.

Guaiacol carbonate sulpho-acid derivative. A. Einhorn. Munich, Assignor to C. H. Boehringer Sohn, Nieder Ingelheim, Germany. U.S. Pat. 938,132, Oct. 26, 1909.

SEE Fr. Pat. 391,601 of 1908; this J., 1908, 1176.—T. F. B.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Photographic developers; The developing power of —. Lumière and Seyewetz. Phot. Mitt., 1909, 46, 260. Chem.-Zeit., 1909, 33, Rep., 852.

THE following are results of tests made on rapid plates, using Chapman Jones' scale-photometer:—Increasing the temperature of development has generally little influence on contrast, but quinol and adanol give greater contrasts at lower temperatures. With most developers increase of temperature increases fog very largely, but there is only a slight increase with edinol, *p*-aminophenol, hydramine, and catechol. Dilution generally causes decrease of contrasts without further liability to fog. In the case of edinol, after the diminution caused by the addition of two volumes of water, no further diminution ensues on further dilution. Except with developers where sodium sulphite is used as accelerator, its further addition does not diminish contrasts. Increase of the proportion of alkali in most alkaline developers has no noticeable effect on contrast. Addition of bromide increases contrasts, prolongs development, and prevents fog-formation.—T. F. B.

Dehydroindigo bisulphite and a new process of indigo dyeing [and printing photographs]. Kalb. See V.

PATENTS.

Photographic films; Manufacture of —. E. Brandenberger, Thaon, France. Eng. Pat. 13,328, June 7, 1909.

CELLULOSE films obtained from aqueous solutions, especially from viscose, are submitted to the action of the various solutions or substances necessary for preparing sensitive surfaces; the first treatment must be either with water or with an aqueous solution, in order to cause the film to swell and become suitably absorbent. For example, the film may first be immersed in a solution of an alkali bromide and then in a solution of silver nitrate. The resulting film may be supported on paper, glass, &c.

—T. F. B.

Colour screens or plates for photography; Manufacture of — J. H. Christensen, Holte, Denmark. Eng. Pat. 21,097, Oct. 6, 1908. Addition to Eng. Pat. 20,971, Jan. 25, 1908 (see this J., 1909, 491).

THREE or more viscous solutions of dextrin, resin, etc., are coloured with the colours desired for the screen or plate, and separately emulsified in a viscous solution, for instance of 30 parts of gum dammar in 35 parts of turpentine oil; by this means the dextrin solution is divided into globules of approximately uniform size. When emulsification is complete, the greater portion of the gum dammar is removed, for example by repeated dilution and decantation with turpentine oil, and the coloured globules are transferred by dilution and decantation into a volatile liquid, preferably petroleum spirit. This liquid is poured on to glass or other plates, which may be coated with a thin layer of lac or caoutchouc; the globules will soon settle, and the lowest layer will adhere to the lac or caoutchouc, whilst the remainder are rinsed off by means of petroleum spirit. When the solvent has evaporated, the globules will cover the plate, but the gum dammar which remains will prevent the different coloured globules from intermingling.—T. F. B.

Photographic film. J. Bourdeaux. Fr. Pat. 401,912, April 9, 1909.

PHOTOGRAPHIC films are prepared by applying a sensitive emulsion to gelatin films which have been coated with a suitable protective varnish or collodion. If desired, the gelatin may first be treated with a chromium salt or with formaldehyde.—T. F. B.

Bichromated-gelatin images; Process for developing — L. Jacobsen. Ger. Pat. 213,772, July 19, 1908.

PEPSIN, or other ferments which decompose albumin, will not decompose bichromated gelatin. If pigmented bichromated-gelatin paper which has been exposed behind a negative, is treated with, for example, a 1 per cent. solution of pepsin containing also 1-5 per cent. of hydrochloric acid, for three hours at 25° C., development will be complete. The advantage of the prolonged development is that it produces finer half-tones.—T. F. B.

Photographic anti-halation plates; Preparation of intermediate films for — J. Hauff und Co. Ger. Pat. 213,774, Jan. 19, 1909.

GLASS plates are coated with a solution of 3 grms. of gelatin and 0.5 grm. of copper sulphate in 100 c.c. of water; when this has set, the plates are immersed in a strong solution of hydroferrocyanic acid, washed, dried, and provided with a sensitive emulsion over this anti-halation film. The copper ferrocyanide thus produced is less actinic than uranium or molybdenum ferrocyanide (Ger. Pat. 210,057), hence a thinner layer suffices.—T. F. B.

Developing exposed silver bromide films in daylight; Process for — R. Freund. Ger. Pat. 213,775, Oct. 11, 1908.

EXPOSED silver bromide films are treated with an alkali iodide solution, which converts the bromide into an insensitive silver iodide; the plates, etc., may then be developed in daylight by means of a strongly alkaline developer, the following formula being recommended:—Quinol, 8 grms.; methyl-*p*-aminophenol sulphate, 1 grm.; anhydrous sodium sulphite, 20 grms.; potassium bromide, 40 grms.; potassium hydroxide, 198 grms.; water, 1200 grms.—T. F. B.

XXII.—EXPLOSIVES, MATCHES, &c.

Explosion which occurred in the corning house of the gunpowder factory of the Chilwarth Gunpowder Co., Ltd., at Fernilee, in the County of Derby, on August 12th, 1909; Circumstances attending an — Major A. Cooper-Key, H.M. Chief Inspector of Explosives. [Cd. 4925.] (See also this J., 1906, 828; 1909, 1664.)

ABOUT half a ton of gunpowder exploded and three lives were lost. The conclusion is arrived at that the explosion

was due to some hard foreign body passing between the rolls; nevertheless an examination did not show any marks, of recent date, of a nature to cause an explosion. Major Cooper-Key points out, however, that the crushing of a moderately hard flat article between the rolls would quite possibly give rise to the development of sufficient heat to fire the gunpowder dust, without leaving a mark of any kind. There was no evidence to show whether this foreign body was carried into the building in one of the barrels containing the presscake, whether it fell from the roof, or whether it was a piece of the machinery itself.

—G. W. McD.

Coal dust; Experiments with — in the testing gallery of the Rossiter coal district, Austria. Czaplinski and Jicinsky. Z. ges. Schiess- und Sprengstoffw., 1909, 4, 415-417. (See also this J., 1909, 42, 260, 511, 692, 748, 1024; 1908, 888, 971, 1143; 1905, 939; 1896, 319.)

THE experiments were carried out with coal dust alone, no pit gas being used. The effect of water sprays, and the influence of dry and wet dust-free zones and of dry stone dust zones were also investigated. The explosives were fired in a chamber 1.3 m. wide, 1.7 m. deep, and 1.85 m. high, which communicated with a gallery 293.7 m. long. The coal dust was placed in this gallery on horizontal or inclined shelves. The pressure developed in the gallery after explosion was measured by a manometer with an automatic registering device. The length of the flame produced was determined by means of sulphur matches fixed in wooden blocks and placed at distances of 1 m. along the length of the gallery. Samples of the gas in the gallery, after the explosion, were collected in flasks. Analyses showed the following composition: Carbon dioxide (0.8-6.45 per cent.), carbon monoxide (0.3-3.2 per cent.), and oxygen (10.9-18.8 per cent.). Two explosives were used—gelatin-dynamite No. 1, and black powder. The gelatin-dynamite was fired by means of a 1 grm. detonator whilst freely suspended. The black powder was fired from a mortar with a bore 450 mm. deep and 27 mm. diameter, and the only stemming used was a paper plug 3 mm. thick.

Coal dust.—The natural coal dust from the mines was used and it was not in any way pulverised, as was the case, for instance, at Althof's (*loc. cit.*). The finest sample used left a residue of only 3.8 per cent. on a sieve of 3480 meshes to the sq. cm.; the coarsest a residue of 19.5 per cent. on a sieve of 1160 meshes to the sq. cm. The moisture varied from 0.58-4.5 per cent.; ash from 9-17 per cent. and volatile matter from 19.2-22.8 per cent.

Coal dust explosions with gelatin-dynamite.—300 grms. of dynamite when fired in the explosion chamber (free from coal dust) produced a flame of less than 1 m. in length and a pressure of 1.3 atmospheres. No coal dust explosion was caused when 200-300 grms. of dynamite were fired in the gallery, 47 m. from the chamber, in the presence of 12.5 kilos. of coal dust containing 2 per cent. of moisture; nor was there an explosion when the explosive was fired from the chamber in presence of 6 kilos. of coal dust containing 4.5 per cent. of moisture. On using coal dust containing only 0.74-1.02 per cent. of moisture in the explosion chamber, the following results were obtained: With 7 kilos. of coal dust a flame of 16 m.; with 13 kilos. a flame of 37 m. Spreading 30 kilos. of coal dust in the gallery, and keeping it in agitation produced on explosion a flame 106 m. long.

Coal dust explosions with black powder.—The charge, fired from a mortar, was 300 grms. Coal dust (2½ kilos.) kept in suspension in the explosion chamber, produced a flame 15 m. long, which was increased to 30 m. when 10 kilos. of coal dust were spread 5 m. from the chamber. A flame length of 147 m. was obtained with 30 kilos. of coal dust, placed in the gallery some 88 m. from the explosion chamber, and kept in agitation. Different flame lengths were obtained dependent on whether the mortar was placed with its muzzle facing towards the explosion chamber or down the gallery. The moisture content of the coal dust was found to be a very important factor. Where from 2 to 4.5 per cent. of moisture was present, very short flames resulted, and explosions of only a minor nature took place. Water sprays were found to shorten

the flame length very considerably. Wet zones had a similar effect, whilst in a limited number of experiments the use of stone dust was not found to be efficacious.

—G. W. McD.

PATENT.

High explosive. H. Cottu and J. Teyssen. Fr. Pat. 402,693, Sept. 3, 1908.

CLAIM is made for an explosive consisting of a mixture of trinitrotoluene, barium nitrate (or other nitrate) and gun-cotton in proportions varying according to the use for which the preparation is required. An explosive which is particularly suitable for mines and which can be exploded without the use of a detonator may be obtained by mixing trinitrotoluene (10 per cent. or more) with ordinary black gunpowder, and, if desired, compressing the mixture into compact blocks.—C. A. M.

XXIII.—ANALYTICAL CHEMISTRY.

APPARATUS.

Smoke tintometer. J. Lowdon. Engineering, 1909, 33, 627.

THE instrument, which is intended for determining the relative "density" of smoke, consists of a tube with an eye-piece at one end, and two circular apertures at the other. In front of one of these apertures is a diaphragm which can be rotated and has five circular openings of the same diameter as the aperture in the end of the instrument; four of the openings are fitted with tinted glasses corresponding to, and graduated from, the standard tints of Ringelmann's smoke scale. In using the instrument, the free opening in the diaphragm is made to coincide with one of the apertures in the end of the instrument, and the clear sky is observed through this aperture and the smoke through the other. The diaphragm is then rotated until the illumination through both apertures appears to be identical.—A. S.

PATENTS.

Photometer. H. Chapman, Sheffield. Eng. Pat. 22,748, Oct. 27, 1908.

THE light to be tested falls directly on to, or is reflected on to, a radiometer, or on to a screen (*e.g.*, of opalescent, opal, or ground glass) interposed between the source of light and a radiometer. On the other side of the radiometer, and opposite the screen, is a small aperture, so placed, that when the wings of the radiometer revolve, light is alternately admitted through, and cut off from, the aperture; again, the aperture may be placed in any convenient position, the light being reflected through it by a mirror or the like. A small cut-off shutter, operated by clockwork or other device, is interposed between the radiometer and the aperture, so that the flashes of light may be allowed to pass through the aperture for any given period, the number of flashes, which indicate the candle power of the source of light, being counted. A small ampère-meter and a small volt-meter may be attached to the above apparatus when testing electric lamps, or a gas-meter when testing gas lights. Since the wings of a radiometer revolve at different speeds according to the kind of light falling on them, even when the light is of the same candle power and is placed at the same distance, a compensating device is adopted. This consists of a number of shutters or screens operated by a lever (or levers) moving over a scale. A second compensating device may be provided, consisting of one or more screens (*e.g.*, of opal, opalescent, coloured or ground glass), compensation being effected by the use of different combinations of screens. A schedule or diagram is used for ascertaining the total watts, and watts per candle

power, in the case of electric lights; with a set of diagrams suitably inscribed, the efficiency of any form of light may be ascertained.—L. E.

Gas analysis apparatus; Self-recording —. M. C. Brenot. Fr. Pat. 402,190, April 19, 1909.

THE patent relates to the apparatus described in Fr. Pat. 339,498 (this J., 1908, 1000). The improvements are in the aspirating device, and the control of the three-way cocks and of the recording instrument. The aspirating device is a hollow annular drum with its axis horizontal. The lower part of this drum contains water, and the upper part is divided into two chambers by a radial partition. One of these chambers is always open to the air, and the other is opened alternately to the gas intake and to the measuring vessel by means of a three-way cock. The drum is oscillated about its axis so as alternately to increase and decrease the volume of the gas chamber and thus to pump gas into the measuring vessel. The apparatus is controlled from a continuously rotating shaft. A crank on this shaft carries a flexible plate which engages with a projection on the drum of the aspirating device and rotates the drum in one direction until the plate is turned aside by a fixed cam-surface, the return movement of the drum being effected by a counterweight hanging from a pulley on the spindle of the drum. The three-way cocks are moved to and fro at the required times by two cams on the rotating shaft, by means of rocking levers held against the cams by springs and engaging alternately with a rod connected to the cock. The recording instrument is actuated by an electro-magnet, the circuit being closed at the required time by an arm on the rotating shaft.—A. T. L.

INORGANIC—QUALITATIVE.

Arsenic acid; Detection of — in the presence of arsenious acid by means of magnesia mixture. O. Lutz and R. Swinne. Z. anorg. Chem., 1909, 64, 298–301.

THE authors' experiments lead them to regard magnesia mixture as useless for the detection of arsenate ions in the presence of arsenite ions.—F. SODX.

Reactions of salts in non-aqueous solutions. Naumann. See VII.

INORGANIC—QUANTITATIVE.

Manganese and chromium; [Quantitative] separation of —. F. Falco. Arch. Pharm., 1909, 247, 431–436.

THE ammonium persulphate method of Dittrich and Hassel (this J., 1903, 230) for the separation of manganese and chromium gives good results. Kassner's method (Arch. Pharm., 1894, 232, 229) requires modification. The substance which should not contain more than 0.01 to 0.02 gm. of manganese is dissolved and treated with excess of sodium peroxide. The precipitate is filtered off, washed and dissolved in warm 20 per cent. hydrochloric acid. The solution is now treated with excess of bromine water and the manganese precipitated with ammonia. The precipitate is collected, washed and ignited.—F. SODX.

Cobalt; Rapid electrolytic determination of —. P. Bruylants. Bull. Soc. Chim. Belg., 1909, 23, 383–400.

COBALT can be accurately determined from an ammoniacal solution if a cathodic potential of 1.35 volts is maintained; if the cathodic potential is not regulated, satisfactory results are only obtained with a current density and voltage much less than are ordinarily used for the determination of nickel. If the ordinary rapid method of determining nickel is applied to the determination of cobalt, this metal is always obtained in a spongy and oxidised condition. Electrolytically precipitated cobalt shows a great tendency to oxidise and redissolve, and must therefore be washed without interruption of the current; in this direction its properties, from the standpoint of electrolytic determination, much resemble those of lead and

manganese. Accurate determinations cannot be made under any conditions from an oxalic acid solution. Cobalt and zinc cannot be electrolytically separated by Fischer's method, from an ammoniacal solution containing sodium sulphite; for although cobalt is thus precipitated free from zinc, it absorbs large quantities of sulphur. An approximate separation of the two metals may be effected from an ammoniacal solution with a cathodic potential of 1.35 volts.—E. F.

XXIV.—SCIENTIFIC & TECHNICAL NOTES.

Ozone; Demonstration of the presence of —, in flames. W. Manchot. Ber., 1909, 42, 3948—3951.

SILVER at 240° C., exposed to the tip of a flame, affords a most delicate test for the presence of ozone. In this way

it is easy to demonstrate the presence of ozone in the oxyhydrogen flame, in the coal-gas and air blowpipe flame, and in the carbon monoxide flame—in air with difficulty, in oxygen much more readily. Neither hydrogen peroxide nor nitrogen oxides produce the same black stains as ozone.

The presence of hydrogen peroxide in hot flames can be demonstrated by directing them against the surface of a solution of a titanium salt; in this way it can be shown in the oxyhydrogen flame, and in the carbon monoxide flame fed with oxygen, provided in the latter case the gases are moist. This shows that the production of hydrogen peroxide is a result of the temperature, and not a stage of the reactions occurring in the burning of hydrogen and oxygen.—J. T. D.

PATENT.

Tobacco; Process of renovating, cleansing, and aromatising —. S. B. Heddles, Janesville, Wis. U.S. Pat. 937,801, Oct. 26, 1909.

Tin: tobacco is spread out in a receiving vessel and sprayed with an atomised liquid composition (a liquid containing formaldehyde and water, or formaldehyde, wines, and spirits) which retains moisture and prevents the growth of mould. The tobacco is kept in a moist condition after spraying, until the composition is absorbed and the material is softened and conditioned for handling. The individual leaves are then sprayed a second time with the composition, and the tobacco is kept moist until the composition is again absorbed.—L. E.

Trade Report.

German chemical industries. Oil, Paint, and Drug Rep., Oct. 25, 1909.

At a meeting of the Association for the Protection of the Interests of the German Chemical Industry, held recently at Bonn, it was reported that the German chemical industries showed an increase of only 0.72 per cent. in the number of persons employed in the year 1908, and the total amount of wages paid increased only 2.6 per cent. The exports of German chemical products decreased in the same year by £1,476,000 in value, of which the decrease under the head of coal-tar colours alone amounted to £1,333,000. The decrease in sales brought about an increase in the cost of production, and in the meantime prices had to be cut on account of keener competition. The average profit on the capital invested receded in 1908 from 11.16 per cent. to 9.25 per cent.

The transactions in the tar-colour industries fell off 32.7 per cent. as compared with 1907. In the gunpowder and high-explosives trade the decrease was 22 per cent.; in trades relating to pharmaceutical, photographic, and technical preparations, 9 per cent.; in the alkali salts and acids trades, 7.3 per cent.; and in the artificial fertiliser trade, 2.8 per cent.

Books Received.

HISTORY OF CHEMISTRY. Sir EDWARD THORPE, C.B., LL.D., F.R.S. Vol. I. From the Earliest Times to the Middle of the Nineteenth Century. Watts and Co., 17, Johnson's Court, Fleet Street, E.C. 1909. Price 1s. net.

 26,024. Daniell. Cop tubes.* Nov. 10.
 26,025 to 26,028. Daniell and Hebden. Dyeing yarn or the like.* Nov. 10.
 26,029. Daniell and Hebden. Dyeing apparatus.* Nov. 10.
 26,150. De Ferranti. Treatment of fibrous material. Nov. 11.
 26,253. Oppenheim. Producing damask effects on fabrics by printing. [Ger. Appl., Nov. 12, 1908.]* Nov. 12.
 26,317. British Cotton and Wool Dyers' Assoc., and Robson. Machine for mercerising, dyeing, bleaching, &c., cotton or other vegetable fibre or fabrics. Nov. 13.

COMPLETE SPECIFICATIONS ACCEPTED.

- 23,171 (1908). Corron. Machines for dyeing yarns, &c. Nov. 10.
 25,441 (1908). Corron. Machines for dyeing or otherwise treating yarns. Nov. 17.
 7617 (1909). Friedrich. Production of a dissolved substance for use in making artificial threads, &c. Nov. 17.
 8976 (1909). Moller-Holtkamp. Piece-dyeing heavy and close fabrics with Turkey red. Nov. 10.
 15,341 (1909). Bright and Bros., Ltd., and Oldroyd. Colouring yarns for making carpets, &c. Nov. 10.
 24,404 (1909). Schumacher and Resch. Apparatus for dyeing wound yarn. Nov. 17.

VII.—ACIDS, ALKALIS, AND SALTS.

APPLICATIONS.

- 25,082. Gerrard. Treatment of salt. Nov. 1.
 25,111. Norsk Hydro-Elektrisk Kvaestofaktieselskab. Manufacture of ammonium nitrate. [Norw. Appl., Nov. 4, 1908.]* Nov. 1.
 25,203. Pope. Manufacture of lead oxide. Nov. 2.
 25,459. Jensen (Spitz). Production of pure tin oxide. [Addition to No. 28,565 of 1908.]* Nov. 4.
 25,460. Pettigrew. Saturator for sulphate of ammonia and other salts. Nov. 4.
 26,140. Rollin and Hedworth Barium Co. Manufacture of barium oxide. [Comprised in No. 27,587, Dec. 18, 1908.] Nov. 11.
 26,175. Pope. Manufacture of lead oxide. Nov. 12.
 26,206. Lloyd. Treating nitrate of lime to prevent deliquescence. Nov. 12.
 26,258. Swan and Kendal. Apparatus for making alkali cyanides. Nov. 12.
 26,263. Freeth and Coekesedge. Manufacture of ammonium chloride from ammonium sulphate and common salt. Nov. 12.
 26,264. Ormandy and Kay. Manufacture of borax, soap, soap powder, soda, &c. Nov. 12.

COMPLETE SPECIFICATIONS ACCEPTED.

- 23,889 (1908). Frerichs. Production of ammonia. Nov. 17.
 26,068 (1908). Hodgkinson. Apparatus for evaporating brine or other solutions. Nov. 17.
 26,257 (1908). Eckford. Manufacture of lead oxide. Nov. 10.
 7495 (1909). Chem. Werke vorm. Dr. H. Byk. Manufacture of solid durable perborate preparations. Nov. 10.
 22,034 (1909). Jaubert. Production of oxygen. Nov. 17.

VIII.—GLASS, POTTERY, AND ENAMELS.

APPLICATIONS.

- 25,146. Hewitt. Drying and burning or calcining slip, slurry, chalk, clay, &c. Nov. 1.
 25,692. Fletcher. Enamelling muffles. Nov. 8.
 25,908. Kempton. Regenerative glass furnace.* Nov. 9.
 26,309. West and Lewis. *See under IX.*

COMPLETE SPECIFICATION ACCEPTED.

- 6560 (1909). Weber. Making slip from clays, porcelain, earth, &c. Nov. 10.

IX.—BUILDING MATERIALS. CLAYS, MORTARS, AND CEMENTS.

APPLICATIONS.

- 25,146. Hewitt. *See under VIII.*
 26,309. West and Lewis. Kilns or ovens for firing bricks, tiles, pipes, china, &c. Nov. 13.

COMPLETE SPECIFICATIONS ACCEPTED.

- 26,416 (1908). Wade. Black concrete or stone cement. Nov. 17.
 13,091 (1909). Langenbeck. Vitrified paving brick or block. Nov. 17.
 21,670 (1909). Sinclair. Cement. Nov. 17.

X.—METALS AND METALLURGY.

APPLICATIONS.

- 25,152. Simpson and Oviatt. Production of refined iron and of steel directly from iron ore. Nov. 1.
 25,244. Kjellin. Treatment of ores in blast furnaces.* Nov. 2.
 25,263. Felten und Guillaume Lahmeyerwerke. Converters. [Ger. Appl., Nov. 30, 1908.]* Nov. 2.
 25,809. Swan. Apparatus for separating liquids from finely-divided solids, especially for treating gold ores, slimes, &c. Nov. 9.
 25,847. Mason. Recovery of pure antimony from ores, &c.* Nov. 9.
 25,889. Kuzel. *See under II.*
 25,915. Jensen. Separation of tin or other metals from waste metal, alloys, &c. [Addition to No. 28,551 of 1908.]* Nov. 9.
 25,979. Lindblad and Stalhane. Reduction of zinc. [Swed. Appl., Nov. 11, 1908.]* Nov. 10.
 26,019. Sulman and Picard. Treatment of oxidised ores. Nov. 10.

COMPLETE SPECIFICATIONS ACCEPTED.

- 16,667 (1908). Dick. Treatment of copper and other ores. Nov. 17.
 20,752 (1908). Lyon. Apparatus for washing and separating ores, minerals, &c. Nov. 10.
 23,529 (1908). Sterne (Block). Desiccation of air for metallurgical operations. Nov. 10.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

APPLICATIONS.

- 25,096. Cowper-Coles. Apparatus for electro-deposition of iron. Nov. 1.
 25,118. Imray (Soc. Chem. Ind. in Basle). Continuous electrolysis of aqueous solutions.* Nov. 1.
 25,251. Härdén. Electric furnaces.* Nov. 12.
 25,266. Härdén. Electric furnaces.* Nov. 12.

COMPLETE SPECIFICATIONS ACCEPTED.

- 24,597 (1908). Winkler. Production of transparent, flexible, infusible insulating materials. Nov. 17.
 27,034 (1908). Vollert. Electrolytic cleaning of metal objects to be galvanised or nickelled. Nov. 17.
 4175 (1909). Ruthenburg. Electrodes for electric furnaces. Nov. 17.

XII.—FATTY OILS, FATS, WAXES, AND SOAPS.

APPLICATIONS.

- 25,321. Chambers and Moffatt. *See under V.*
 25,904. Hollands. Soap. Nov. 9.
 26,264. Ormandy and Kay. *See under VII.*

COMPLETE SPECIFICATIONS ACCEPTED.

- 8674 (1909). Grant. Manufacture of soap. Nov. 10.
 8982 (1909). Welter. Manufacture of soaps containing solvents of fat. Nov. 17.

XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, &c.

(A.)—PIGMENTS, PAINTS.

APPLICATIONS.

- 25,203. Pope. *See under VII.*
 26,175. Pope. *See under VII.*

COMPLETE SPECIFICATIONS ACCEPTED.

- 24,627 (1908). Palk, Basset, and Nash. Paint, especially for use as anti-fouling composition for ships. Nov. 17.
 25,216 (1908). Hofmann and Main. *See under I.*

(B.)—RESINS, VARNISHES.

APPLICATION.

- 25,944. Coleman. Heating or treating varnish, &c.* Nov. 10.

COMPLETE SPECIFICATION ACCEPTED.

- 3074 (1909). Sprenger. *See under III.*

(C.)—INDIA-RUBBER.

COMPLETE SPECIFICATIONS ACCEPTED.

- 27,567 (1908). Capelle. Recovery or regeneration of indiarubber and similar products. Nov. 17.
 12,250 (1909). Clark. Apparatus for cleaning and devulcanising rubber. Nov. 10.

XIV.—TANNING, LEATHER, GLUE, SIZE, &c.

APPLICATIONS.

- 25,842. Riches and Nelson. Preparing hides and skins for tanning and dressing. Nov. 9.
 26,040. Nance. Process of tanning. Nov. 10.
 26,231. Lehmann. Manufacture of vegetable glues. Nov. 12.

COMPLETE SPECIFICATIONS ACCEPTED.

- 25,216 (1908). Hofmann and Main. *See under I.*
 19,804 (1909). Deutsche Versuchsanstalt f. Lederindustrie. Decolorising tannin extracts. Nov. 19.

XVI.—SUGAR, STARCH, GUM, &c.

APPLICATION.

- 25,121. Flick. Manufacture of soluble starch.* Nov. 1.

COMPLETE SPECIFICATION ACCEPTED.

- 2219 (1909). Wynberg and Wynberg. Treatment of sugar cane. Nov. 17.

XVII.—BREWING, WINES, SPIRITS, &c.

COMPLETE SPECIFICATION ACCEPTED.

- 4604 (1909). Vallat. Apparatus for distilling or rectifying wines, brandy, fermented worts, alcohols, petrols, essential oils, benzines, &c. Nov. 10.

XVIII.—FOODS; SANITATION, WATER PURIFICATION; AND DISINFECTANTS.

(A.)—FOODS.

APPLICATIONS.

- 25,773. Wülfing. *See under XX.*
 25,956. Martin and others. Curing and ageing tobacco and like vegetable substances. [U.S. Appl., Nov. 30, 1908.]* Nov. 10.
 26,007. Carballé. Fermentation of milk.* Nov. 10.

(B.)—SANITATION; WATER PURIFICATION.

APPLICATIONS.

- 25,587. Schneider. *See under XIX.*
 25,665. Paul. Hardening abnormally soft water.* Nov. 6.

COMPLETE SPECIFICATIONS ACCEPTED.

- 23,651 (1908) and 6492 (1909). Morrison and Warren. Appliances for use in treating sewage effluent and the like. Nov. 10.
 5656 (1909). Schultze. Purification of water. Nov. 17.
 8593 (1909). Antoine. Apparatus for separating foreign substances from water. Nov. 17.

(C.)—DISINFECTANTS.

APPLICATION.

- 25,472. Chem. Fabr. Ladenburg. Disinfecting process. [Ger. Appl., May 24, 1909.]* Nov. 4.

XIX.—PAPER, PASTEBOARD, &c.

APPLICATIONS.

- 25,587. Schneider. Water-purifying apparatus for paper and like factories. Nov. 5.

- 25,771. Geller. Manufacture of paper and cardboard.* Nov. 8.

- 25,875. Pearson and Stoneham. Manufacture of paper. Nov. 9.

COMPLETE SPECIFICATIONS ACCEPTED.

- 16,327 (1908). Milne. Machines for sizing and coating paper. Nov. 10.

- 24,131 (1908). Herz. Treatment of waste paper and fibrous materials in the preparation of paper pulp. Nov. 10.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENTIAL OILS, AND EXTRACTS.

APPLICATIONS.

- 25,138. Chem. Pharm. Laboratorium "Sahir." Producing a dry formaldehyde compound. [Ger. Appl., Dec. 19, 1908.]* Nov. 1.

- 25,470. Einhorn. Manufacture of benzoysalicylic acid. [Ger. Appl., Nov. 13, 1908.]* Nov. 4.

- 25,678. Sefton-Jones (Quade). Preparation of sodium glycerophosphate. Nov. 6.

- 25,773. Wülfing. Preparing salts of lactalbumen. [Addition to No. 6179 of 1908.]* Nov. 8.

COMPLETE SPECIFICATIONS ACCEPTED.

- 26,075 (1908). Belart, and Digit Disinfectant Co. Production of compounds for internal use. Nov. 17.

- 3074 (1909). Sprenger. *See under III.*

- 4604 (1909). Vallat. *See under XVII.*

- 13,912 (1909). Zimmermann (Chem. Fabr. auf Aetien, vorm. E. Schering). Manufacture of cerium phenol compounds. Nov. 10.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

APPLICATION.

- 25,998. Ruth. Colour photography. [Ger. Appl., Nov. 12, 1908.]* Nov. 10.

COMPLETE SPECIFICATIONS ACCEPTED.

- 3601 (1909). Späth. Manufacture of a screen for colour photography. Nov. 10.

- 14,407 (1909). Danzer. Recovering the material of the support of cinematograph films and the metallic silver of the pictures. Nov. 10.

XXII.—EXPLOSIVES, MATCHES, &c.

APPLICATIONS.

TECHNICAL GAS CALORIMETRY.

BY J. H. COSTE, F.I.C.

When a fuel containing unoxidised or partially oxidised carbon and hydrogen, in any form, is burnt under suitable conditions the carbon is burnt to carbon-dioxide and the hydrogen to water; it depends on the conditions under which combustion takes place whether the water vapour formed is condensed or not. If it is condensed the latent heat of vaporisation of the whole of the water formed is included in the heating value of the fuel. When this happens the calorific value thus obtained is called the gross calorific value. It is only in such appliances as geysers that the heat given out from the water vapour in this way is utilised. In most cases the net calorific power, *i.e.*, the heat evolved by combustion when all the water is kept in the form of vapour, is all that can be utilised in heating appliances. The difference between gross and net calorific power is, therefore, a measure of the total amount of hydrogen present in a fuel.

It is obviously convenient to state the calorific power of gases in units of heat per unit volume. On the Continent the cubic metre is usually used in conjunction with the (great) calorie. In this country illuminating gas is bought and sold, under various Acts governing the gas industry, by the cubic foot, and all the results of statutory testings are corrected to a cubic foot at 60° F. and 30 in. barometer. The official testings of illuminating gas in the Metropolis are returned in calories per cubic foot and the only parliamentary standard for calorific power of illuminating gas is expressed in this manner. In all figures given in this paper the calorific power is expressed according to this official usage. The number of calories multiplied by 3.968 gives British Thermal Units.

I.—CALORIMETRY.

Any calorimetric method should give a means of determining, with such accuracy as may be possible, both gross and net calorific power. This object may be attained by either an indirect or a direct method.

A.—*The indirect method of determining calorific power.*—The researches of Julius Thomsen and of Berthelot have placed at our disposal values for the heat of combustion

of hydrocarbons and other combustible gases and vapours which are sufficiently reliable for most purposes. By means of these it is possible, if the composition of a gaseous mixture is known, to calculate its total calorific power.

In the case of coal gas and similar mixtures a difficulty arises in connection with the unsaturated hydrocarbons. It is difficult and in most cases impossible to decide their actual nature, and as the various hydrocarbons which may enter into their constitution have very different calorific values the matter is of importance as will be seen from the following table (calculated from Julius Thomsen's figures) giving the calorific values in great calories per cubic foot of various gases (A) measured at 0° C. and 760 mm., and (B) at 15.5° C. (60° F.) and 762 mm. (=30") the products in each case being cooled to 18° C.

Table I.

	(A.)		(B.)	
	gross.	net.	gross.	net.
Methane	268	240.5	254.3	228.2
Ethane	468	427.0	444.0	405.2
Ethylene	421	394	399.5	373
Propylene	622	581	590.2	551.3
Acetylene	392	378	371.9	358.7
Benzene	1010	969	958.3	919.4
Hydrogen	86.4	72.8	82.0	69.1
Carbon monoxide	85.9	85.9	81.5	81.5

It will be noticed that the difference between gross and net calorific power for each molecule of water formed by the combustion of a molecule of the gas is in (A) 14 calories, and in (B) 13 calories per cubic foot. In other words the difference between gross and net calorific power multiplied by $\frac{1.00}{1.14}$ or by $\frac{1.00}{1.13}$, as the case may be, will give the total percentage of hydrogen in the gas.

A gas, the calorific power of which had been found by direct means to be gross, 150.3 calories, net, 133.2 calories, was found to have the composition indicated below. The unsaturated hydrocarbons were assumed to be (1) ethylene, (2) propylene, (3) butylene.

Table II.

Composition.	Calorific power (calculated).			
	(1) gross.	(2) gross.	(3) gross.	
Carbon dioxide	nil	—	—	—
Oxygen	0.27	—	—	—
Unsaturated hydrocarbons	5.38	21.52	31.74	41.96
Carbon monoxide ..	13.09	10.73	10.73	10.73
Hydrogen	42.45	34.85	34.85	34.85
Methane	27.71	70.43	70.43	70.43
Nitrogen	11.10	—	—	—
	100.00	137.53 cal.	147.75 cal.	157.97 cal.
Per cent. total hydrogen	—	108.63	114.01	119.39
Deduction for latent heat	—	14.10 cal.	14.82 cal.	15.51 cal.
Net calorific power	—	123.43 "	132.95 "	142.40 "

It will be seen that the assumption that the unsaturated hydrocarbon is propylene gives results closely approaching those found experimentally. It is in fact found to be a good working convention for general purposes that the average calorific value of the unsaturated hydrocarbons is equal to that of propylene. The following table serves to illustrate the agreement between results calculated in this way and those obtained directly.

Table III.

Experimental.		Calculated.	
Gross.	Net.	Gross.	Net.
166.6*	149.3	167.4	150.0
150.3	133.2	148.2	132.8
143.0	127.7	143.2	128.2
148.0	130.3	143.5	128.5
143.5	127.0	143.6	128.6
145.7	129.3	143.9	128.8
145.8	131.0	147.3	131.8
143.3	128.3	144.7	129.2
143.1	126.2	140.0	125.6
152.6	134.2	152.3	134.9
143.5*	127.7	142.5	128.5
145.7*	129.3	143.8	128.3
144.5*	129.5	146.3	130.5

* Pure coal gas.

B.—*Direct methods of determining calorific power.*—Various forms of calorimeter have been devised for determining the calorific power of gases. They all depend on a known amount of water being heated to a measured extent by a known volume of gas. Two principal types of calorimeter have been proposed (a) in which a small and usually a fixed amount of gas is allowed to burn out and to heat a small and fixed amount of still water, (b) in which gas burnt at a measured rate is allowed to heat to an observed temperature a constant stream of water, a definite amount of which is collected during the period of observation. In the former class the highest temperature of a rise—a transient equilibrium—is noted, and in the latter the temperature which is reached as the result of a continuous equilibrium. The flow calorimeters are to all intents “geysers” in which special care is taken to insure complete combustion of the gas and complete absorption of the heat evolved. In either case it is obviously desirable that the proportions of gas burnt and water heated should be so adjusted that the rise of temperature may always be sufficiently great to insure reasonable sensitiveness of reading and not high enough to render loss by radiation a serious consideration. This optimum range of rise will vary in different instruments according to the efficiency of the measures taken to prevent radiation.

For the determination of the calorific value of a gas supply of any kind which can be burnt in practically unlimited quantities no doubt the flow type of calorimeter is the better, as the apparatus can be adjusted to remain in a state of thermal equilibrium for a considerable time, during which a relatively large volume of gas can be burnt and measured, and a correspondingly large volume of water heated and measured. Several readings of the temperature of the water at inlet and outlet can be taken and average temperatures computed for both inlet and outlet with a high degree of accuracy. The amount of water condensed in the abstraction of heat from the products of combustion can also be arranged to be sufficiently great to secure a good determination of net calorific power.

On the other hand the classical work of both Thomsen and Berthelot was carried out in calorimeters of the burn-out and fixed water type,* and for technical purposes both Hempel's and Simmance and Abady's portable calorimeters, which are of this type, give, if carefully adjusted and used, results of a fair degree of accuracy. Only the gross calorific power is determined in the two latter instruments.

Calorimeters of the still water type have been devised by Berthelot (bomb), Thomsen, Fischer, Hempel, Simmance and Abady, and of the flow type by Hartley, Junkers, Boys, and others.

It is, perhaps, desirable to summarise the principal features of some of the more important of these instruments

(A) STILL WATER CALORIMETERS.

Hempel's calorimeter.—This instrument which has been fully described in this Journal (1901, p. 880) is adapted for the combustion of small quantities—2 to 3 litres—of gas. The instrument is calibrated by means of pure hydrogen. No correction is made for radiation, and no precautions are taken to guard against loss of heat from this or other causes. No doubt if the calorific power of a gas is not very different from that of hydrogen the results obtained are fairly accurate, but in the case of coal gas the loss of heat by radiation would be greater and with producer gases less than with hydrogen. In an example given the rise of temperature for a reservoir full of hydrogen was 10.838°, which seems to be a rather large rise to measure in an unjacketed vessel. This is essentially a laboratory, not a field apparatus.

Simmance and Abady's portable calorimeter.—In this instrument the gas is collected in a holder capable of containing considerably more gas than is required for the actual determination. The gas is burnt from a small open tube burner like a Bunsen without the side holes. The calorimeter itself has an outer casing of polished metal separated from it by an air space. It consists of (1) two parallel cylindrical chimneys of different diameters communicating by means of a drum-shaped vessel into which their upper ends open and (2) water jackets for each of the chimneys opening into a larger one surrounding the upper drum-shaped vessel. This water vessel is covered and has a neck through which a cork can be inserted either for the purpose of shaking or to carry a thermometer. A suitable stand holds the calorimeter at such a height that the burner can be slid under the broader chimney which serves as a combustion chamber, the narrower one being for the escape of the exit gases after passing up the wide chimney and communicating their heat to the water during their passage across the drum, which has thin metal spirals depending from its inner upper surface. These serve both as baffles and collectors of heat. About 1 litre of water is placed in the vessel, the quantity varying according to the heat capacity of the instrument. The calorimeter is well shaken and the temperature of the water taken. The holder having been filled with gas is arranged to deliver, and the gas is lit as it issues from the burner. When the water confining the gas has risen to a certain mark, indicating that the proper quantity of gas is now in the holder, the burner is slid under the chimney and this quantity—about 0.05 cubic foot—allowed to burn out. The rise in temperature is noted after shaking, and this, with the amount of water and the known constant of the instrument, gives the data necessary for the calculation of the gross calorific power. It is best to calibrate the instrument with gas of known calorific power—preferably approximating to that of the kind of gas for which the instrument is most likely to be used.

(B) FLOW CALORIMETERS.

Flow calorimeters may be considered as of two classes (1) those in which the passage of both water and gas through the apparatus is, by one or many paths, very short and rather of the nature of a parallel arrangement and (II) those in which the water flows through a long tube around which the air slowly passes. The former class includes most of the flow calorimeters, Junkers' being both the best and the best known. Boys' instrument is the only representative of the latter.

Junkers' calorimeter is one of the earliest and best of its kind. A very good description with illustrations is given in this Society's Journal (1895, p. 631) by Hermann Kühne. The calorimeter is portable, fairly convenient and accurate, the height of the instrument and distance apart of the thermometers are the most inconvenient features. An arrangement exists for determination of net calorific power by measuring the condensed water. The calorimeter is sealed and apparently would hardly be worth repairing in case of leakage. The water content of this calorimeter is about 1700 c.c.

The method of using Junker's calorimeter is somewhat similar to that described for Boys' calorimeter. See, below.

* The difficulty of preparing large quantities of pure gases no doubt helped to determine this choice.

Boys' calorimeter was designed by Mr. C. V. Boys, in his capacity as a Metropolitan Gas Referee, for the purpose of official testings in the County of London. It is described in the Proceedings of the Royal Society (A. Vol. 77 1906, p. 122), in the Notification of the Metropolitan Gas Referees and in this Journal (1906, p. 234; 1907, p. 355). The water content of the coil and equalizing box is only 300 c.c. and of the space in the vessel used as a casing and to collect condensed water is only 400 c.c. up to the overflow. Another feature peculiar to this instrument is the free passage of the products of combustion through the apparatus. Mr. Boys is of opinion that "an inversion of the usual plan is essential to secure uniformity in the outlet temperature; that, in fact, the gases should have plenty of space to pass gently through the instrument and that the water should be taken through every channel strictly in series, all alternative parallel flow being prejudicial."

The instrument is convenient to manipulate, and it is not unduly subject to damage. The fact that it can be kept when not in use in an alkaline solution is a great advantage from the point of view of permanency.

It has stood the practical test of daily usage for nearly three years in each of the 19 gas testing places under the control of the London County Council. The most serious defect noticed has been leakage from the coils or unions. This can be tested for by placing the calorimeter in situ allowing it to drain well*, and then allowing water to flow at the usual rate for the same time as that during which the condensed water is collected. An appreciable collection of water indicates a leakage. It appears improbable that any other calorimeter at present in use would stand constant usage as well as this does when fairly treated. Certainly no other calorimeter is so easily taken to pieces for repair or for examination.

The official method of using the Boys calorimeter is described in the Notification of the Gas Referees. It is briefly as follows.—When a thermal balance has been established the temperatures of inlet and outlet water are taken at intervals during the combustion of $\frac{1}{3}$ cubic foot of gas and the water flowing through the instrument during this period is measured. The difference between the average inlet and outlet temperatures $\times 3$ and by the litres of water collected gives the *gross calorific power*. The condensed water is collected with the gas burning at the same rate as during the above experiment for not less than $\frac{1}{2}$ hour, and from its volume and the *gross calorific power* the *net calorific power* is calculated. A correction is made for the gain or loss to the system due to the flow of gases through the apparatus, and based on the difference of temperature between inlet and exit air, the composition of the exit air and the specific heat of its constituents. The above method of working is applicable to the Junkers of other similar apparatus. It is better to allow $\frac{1}{2}$ hour to elapse after starting before collecting condensed water as the surface of the coils is large, and water only runs down quite slowly. It is necessary to place the calorimeter centrally in the outer vessel as otherwise the flow of condensed water is very irregular. It would be an improvement to have three centring studs fixed inside the outer vessel or on the calorimeter casing.

Sources of error affecting the results obtained from flow calorimeters.—The following sources of error for the effects of which due allowance may be made are likely to affect the results of calorimeters of the Junkers or Boys type.

(1) Heat lost or gained in the exit gases according as they are hotter or cooler than the inlet air. (2) Heat lost or gained by condensation or evaporation of water during the passage of air through the calorimeter. (3) Losses by radiation from the body of the calorimeter. (4) Errors due to the assumption that 1 litre of water weighs one kilogramme. The values of these errors and the proper assignment of corrections to gross or net calorific power have been worked out in the case of the Boys' instrument.

(1) The volume of exit gas compared with that of gas

burnt has been determined by analysis of both gases. See table IV.

TABLE IV.

	I.	II.
Rate of burning, feet per hour	4.6	4.6
Carbon dioxide formed on explosion of gas, per cent.	56.0	57.1
Composition of exit gas.		
Carbon dioxide	8.76	8.52
Oxygen	6.17	4.47
Ratio—gas : air	1 : 6.9	1 : 7.2
gas : exit gases	1 : 6.4	1 : 6.7

The heat capacity of the products from 1 cubic foot of gas, on the assumption that 7 feet are obtained is about 0.06 cal. Experiments under varying conditions have led Boys to adopt the empirical correction of $\frac{1}{6}$ cal. for a difference of 1° between inlet and outlet air, indicating that other influences are included in this correction which under any conditions is small.

(2) If the temperature of the exit gases is above the dew point of the atmosphere of the laboratory, the exit gases which are fully saturated—will rob the system of an amount of heat equal to the latent heat of vaporization of the additional water contained in them and further the amount of condensed water will be reduced to a corresponding extent. On the other hand if the exit gases are cooler than the temperature at which dew is deposited in the laboratory the calorimeter will gain an amount of heat and of water corresponding to the reduced water-holding capacity of the air.

The extreme magnitude of this error can be illustrated by an example. Suppose the temperature of the laboratory to be 21°C . and the air fully saturated with aqueous vapour the temperature of the water supply being low, the exit gases having a temperature of only 10°C . If during the burning of 1 cubic foot 7 feet of these gases pass through the instrument corresponding to $7\frac{1}{2}$ feet of air entering the total amount of water vapour entering will be 4.3 grms. (0.5 grms. in gas + 3.8 grms. in air). The total amount of water leaving will be 1.8 grms. and the excess water condensed ($4.3 - 1.8$) = 2.5 grms. The heat of vaporization of 1 gm. of water at 100°C . is 0.536 great calorie, and at 0° is variously given as from 0.589 to 0.606 so that in any case not more than $2.5 \times 0.6 = 1.5$ calorie per foot of gas burnt could be the amount of error due to this cause. The ease of a low dew point and high outlet temperature may also be considered. It is seldom that the humidity of the atmosphere is less than $\frac{1}{3}$ of the maximum and the temperature of exit gases is seldom above 25° . Assuming both of these conditions and an air temperature of 21° the water vapour entering during the burning of 1 cubic foot would be $0.51 + \frac{7.5 \times 0.51}{3} = 1.78$ grms. and that

leaving the apparatus 4.55 grms., so that in this case the total loss would be 2.77 grms. per cubic foot = 1.66 calorie per cubic foot of gas burnt. That is, under quite extreme conditions the *gross* calorific power as determined without correction may be ± 1.6 calories from the truth owing to differences of humidity of the atmosphere. As the water condensed or evaporated gives up or takes away a corresponding amount of heat the *net* calorific power is unaffected.*

* The following table calculated from Regnault's values for water in 1 kilo. of saturated air was used in the above calculations.
Weight of water in 1 c.f. of gas saturated at $^\circ\text{C}$.

t.	Grms. water.	t.	Grms. water.
10	0.26	18	0.43
11	0.28	19	0.45
12	0.30	20	0.48
13	0.32	21	0.51
14	0.35	22	0.54
15	0.36	23	0.57
16	0.38	24	0.61
17	0.40	25	0.65

* It is best to leave it overnight.

(3) It is difficult to conceive that an instrument so well designed as Boys' calorimeter should allow appreciable loss by radiation or conduction. The outer casing is bright nickel, between this and the casing of the coils is an air space. The outer coil has cold water, usually at a lower temperature than the surrounding air circulating through it. A brattice of sheet brass lined with cork dust separates the outer coil from the inner hotter coil and the mixing chamber.

(4) The temperature of exit water varies between, say 24° and 40° C. The following table shows the percentage error caused by the supposition that 1 litre of water measured at various temperatures has a weight equal to 1000 grms.

TABLE V.

Temperature	Percentage amount of error (+)
20°	0.177
25°	0.293
30°	0.433
35°	0.594
40°	0.776

That is, for gas of 150 calories gross calorific power the results, both gross and net would be too high by from 0.26 to 1.16 calories according to the temperature of exit water.

Junkers' and Boys' calorimeters may be considered as the two most in use for practical purposes and it may be well to discuss at some length their respective advantages and disadvantages and the necessity for applying certain corrections to the results obtained with them.

Although both instruments are fairly portable the Junkers certainly has the advantage in this respect: its simplicity and the fixed arrangement for obtaining a proper head of water render it particularly suitable for fitting up in any locality. The flow of water can easily be regulated by means of the quadrant tap and for gases of very varying calorific power the use of a Bunsen flame enables perfect combustion to be attained at any reasonable rate of consumption. The rise of temperature attained by the exit water can be kept constant by altering the amount of water passing through the instrument. The Boys' instrument is easier to read owing to both thermometers being on the same level. It is more sensitive to rough handling.

The temperature of the exit water is more constant in the Boys' than the Junkers instrument as the following examples will show:—

There appears to be no reason to suppose that the average of several readings does not in either case accurately represent the average temperature of outlet water.

The behaviour of both instruments with gas burning at different rates, the water flow being maintained at a constant rate, is satisfactory as shown in the following series of experiments:—

TABLE IX.

Consumption of gas in feet per hour.	Calorific power.

3	146.5	130.4	—	—
2	144.2	128.7	146.8	131.9

It has been suggested that combustion is not perfect in the Boys' instrument owing to the use of flat flames instead of atmospheric burners. To test this point a tube was inserted in one of the holes in the top of the calorimeter and the exit gases slowly aspirated (1) over pumice saturated with caustic potash solution (2) sulphuric acid (3) a weighed soda lime tube (4) a column of about 12 in. of heated copper oxide (5) a weighed sulphuric acid tube (6) a weighed soda-lime tube. 8 litres of carbon-dioxide-free products corresponding to nearly 9 litres of exit gases were collected, tubes (3) and (6) had not altered in weight and tube (5) had gained 0.008 grm. (=0.0009 grm. hydrogen); any unburnt carbon should have been oxidised by the copper oxide and weighed as carbon dioxide in (6). The gas* was burning in the calorimeter at 5.3 feet per hour—above the maximum rate allowed in official testings. The error due to imperfect combustion is therefore negligible.

Both instruments may be expected to give the best results when working under the conditions which should prevail in a physical laboratory and both give very good results under conditions much less satisfactory.

II.—The calorific power of gas considered in relation to methods of manufacture and to illuminating power.

The calorific power of gas depends—as undoubtedly does the illuminating power—on its composition. The relation between calorific power and composition is however much more direct than in the case of illuminating

* Ordinary house gas having a gross calorific power of 147 calories was used for this experiment.

DISCUSSION.

Prof. C. V. BOYS said that when calorimetry as a practical question in relation to official testings first arose, he made a great many tests with the Junkers and other calorimeters. He considered that the spasmodic variation of the thermometer at the outlet was objectionable; there were constant little jumps which would make it tiresome for gas examiners to use it. In making tests day by day it was desirable that as much as possible should be done by the apparatus, and that as little as possible should be left for the daily attention and judgment of the user of the instrument. It seemed essential that the outlet thermometer readings should be as smooth and even as that of the inlet water; so that one would merely have to make readings at definite times, and would not have to judge what the fair mean reading would be. The imperfect mixing of parallel flows of water through alternative channels would almost certainly give rise to jumps which no mixing-chamber, such as was at the top of the Junkers instrument, could possibly overcome. There was an instability of conditions which a small mixing-chamber could not possibly overcome. He felt that the difficulty could be overcome only by arranging that the water should take every part of the instrument in series; and that there should be no place where a pocket of water could accumulate until it got hot enough to force its own way on and overwhelm the other stream. He thought he was justified in that conclusion because his own outlet thermometer was free from these jumps, appearing quite constant sometimes for minutes together almost as if it were stuck; and he had not seen that in any other calorimeter. There seemed to be an idea that the real scientific test of the value of gas was the net test; but he was by no means sure that this was a very scientific test, for this reason: In taking a net test, the heat due to the condensation of most of the steam and the cooling of the resulting condensed water to the outlet temperature, was subtracted from the total observed heat, but this did not represent any actual use of the heating power, as the heat given out by the permanent gases in cooling from the boiling point to the outlet temperature was included in the net value. The figure so obtained was absolutely artificial; it meant nothing. As the Gas Referees had prescribed a net test his position might seem inconsistent, but calorimetry was practised largely, and the gross and net values were in universal use long before there was any question of making official testings of the calorific value of gas, and it was obviously desirable in instituting an official test not to depart from recognised practice. There was no reason for selecting one particular net value, even if it did correctly represent the use of gas; every user of gas should be equally entitled to a special net value to meet his requirements. He thought it right to describe the calorific value by the use of calories rather than by B.T.U. It was more easy to obtain appliances, which should be cheap and accurate, based upon the metric than upon our system, and having so made the measurement it was most natural and direct so to state it. With regard to the centering of the instrument inside the case, there would be no difficulty in providing that the inner casing should not bear up against the condensed water outlet.

Mr. J. W. HELPS agreed with the author as to the impossibility of being able to deduce the calorific power from its illuminating power of a gas, and *vice versa*. He carried out some experiments on that point 10 years ago; and the figures now shown agreed closely with those he had obtained. He did not see the necessity for the two tests; the calorific test would be sufficient; the other was really of no practical use. Whatever burner was used for testing illuminating power, the extent to which a reduction could be made was limited by the heating power of the gas; and as it was possible to vary the conditions under which the gas was produced, so as to increase its calorific power while actually reducing its illuminating power, the infliction of a test for the latter stood in the way of the customer being supplied with the most suitable gas for his various purposes. That was an important question which would have to be considered,

and, in his opinion, it would not be long before they had the calorific standard.

Mr. W. J. DIBBIN said that there could be no question but that Professor Boys had devised a thoroughly trustworthy calorimeter, by means of which the calorific value of coal gas could be readily ascertained. The only way of getting a result with the old form of calorimeter was to take a number of observations, expunge any out-of-the-way ones, and take the average of the rest—which was not a very scientific method. This instrument certainly made a great advance. He looked on the ordinary gas photometer as now used as a thing of comparatively little value. He hoped, with Mr. Helps, that the time was not far distant when the calorific test would be the one reliable test of coal gas, so far as it was in use for lighting. It was unnecessary to enter into any discussion of the merits of water-gas; but it was a question to what temperature an incandescent mantle must be raised to produce sufficient light, and what quantity of gas was required to raise a definite quantity of water to a certain temperature for cooking.

Dr. H. G. COLMAN said that the figures given by Mr. Coste agreed closely with those he had obtained during the past 10 years, but he differed from him with regard to the table showing the relation between the results obtained by direct test with the calorimeter, and those calculated from the analysis of the gas. The calorimeter tests were always made with a wet meter, and the results calculated for moist gas at 60° F. and 30 inches Bar., under which circumstances they contained about 1.5 per cent. of moisture; the calculated results were made on the assumption of a dry gas, and if the moisture had been allowed for the calculated results would have come out about 1.5 per cent. lower* than the observed figures. For ordinary purposes it was sufficient to assume that the unsaturated hydrocarbons consisted of propylene, but in the newer methods of manufacture, especially in vertical retorts, the unsaturated hydrocarbons contained a smaller proportion of benzene and higher proportion of ethylene. He trusted that the day would soon come when a calorific standard would be substituted for one of illuminating power, and hoped that Mr. Coste's paper would help that day forward. He fully agreed with Mr. Helps, however, that the imposition of a double standard was much to be deprecated, and believed that in actual working it would soon be found impracticable. He had made thousands of tests with the Junkers calorimeter and had found it an excellent instrument. There were slight jumps sometimes in the reading of the outlet thermometer, but these jumps were only fractions of a degree, and in the ordinary run of a test there was practical agreement between the two instruments. The chief objection to the Junkers calorimeter was the different level of the two thermometers, which necessitated the jumping up and down of the operator during the test.

Mr. G. C. JONES wished to defend one class of manufacturers against the charge of not being able or willing to state the thermal efficiency of the goods they sold. Reputable gas-engine makers would always guarantee the efficiency of their engines. It was true they preferred to speak of so many feet of gas per H.P. hour, and natural that they showed an increasing preference for Manchester gas as the standard, but, if pressed, they would usually guarantee one H.P. hour for so many calories supplied to their engine in the form of gas. It would nearly always be found, however, that they refused to be debited with more than the so-called "net" calories. The general adoption of this term could be traced to certain discussions concerning the efficiencies of gas producers and gas engines which took place ten or fifteen years ago, when its use led to much confusion and some protests. Its adoption improved the paper efficiency of a gas-engine, but that was hardly a reason for retaining in their vocabulary a word which had been characterised by Prof. Boys as unscientific. If the discussion led to the disuse of that ambiguous term, Mr. Coste's paper would be remembered with gratitude by many of them.

* The actual difference according to The Gas Referees' table would be 1.8 per cent.—J. H. C.

Mr. C. J. D. GAIR said he had found the Simmance-Abady calorimeter gave excellent results. With the Junkers calorimeter there was a tendency for the outlet temperature to jump in working; but, with the Simmance-Abady this did not occur, neither was there the difficulty in the flow of the condensed water which in the Junkers was somewhat irregular, and, unless several cubic feet of gas were burned and the products collected, a proper reading was not ensured. A snap test could not be taken accurately with a Junkers calorimeter, but this was possible with the Simmance-Abady. It seemed an excellent suggestion to take propylene as the most correct hydrocarbon from which to calculate, but undoubtedly the calorific test itself was greatly to be preferred in obtaining the heating value of the gas.

Mr. COSTE, in reply, said he was very pleased to hear Professor Boys appreciated the point about the centering of the instrument. It was not made as a merely academical suggestion; but some little time ago they found that the differences between the "gross" and the "net" calorific power in certain results were such as they knew to be quite impossible, and a careful examination of the instrument showed that by placing the calorimeter eccentrically in the outer casing, similar erroneous results were obtained, while, by carefully centering it, the results at once became normal. There seemed to be such a general agreement that his general results were moderately accurate that he felt he had very little to defend. He noted Dr. Colman's point about moist gas; but the fact remained that the figures as calculated did agree very well for all practical purposes. It was always better, of course, to directly ascertain all figures which were capable of being so determined; but the results of analysis were frequently useful in cases where the direct determination would be impossible; and at other times were useful in confirming an observed result. He had stated in the paper that the Junkers was an excellent instrument; there was no doubt about the jumping which had been referred to, but the average temperatures were accurate.

Meeting held at Nottingham on Wednesday, November 17th, 1909.

MR. S. J. PENTECOST IN THE CHAIR.

THE GROWTH OF MICRO-ORGANISMS ON COTTON.

BY S. R. TROTMAN, M.A., F.I.C.

In a recent communication (this J., Nov. 30, 1909, 1180) S. J. Pentecost has called attention to a pink discolouration sometimes caused in cotton goods by the formation of pseudo-mauveine. I have recently investigated a case of discolouration which, although superficially identical and to the eye indistinguishable from this, was nevertheless due to a totally different cause, namely, the growth of a chromogenic mould. The goods in question were examined and passed when finished, but after being stored for a fortnight, developed a faint pink colour so evenly distributed as to give them the appearance of having been dyed. The absence of aniline colouring matters was proved and microscopic examination showed the presence of mould. Cultures were then made from the material, with the result that pure cultures of a mould were obtained which had a rose-pink colour, and which were capable of reproducing the colour of the damaged cotton when sown on sterilised lace and cotton wool containing nitrogenous food material. The colour was not readily developed on gelatin but grew well on a starch medium, particularly in the presence of a trace of an organic acid; in neutral or alkaline media the growth was very slow. The goods in question had been dressed with starch and a little tartaric acid, and thus the most favourable conditions for the growth of the mould were

reproduced. The colonies consisted of very fine mycelia which were closely attached to the surface of the medium, and which only produced aerial colourless hyphae carrying sporangia after an interval of nearly a fortnight. A second batch of the same goods developed the colour while standing after the soda boil, and it was probable that this was the point of infection. The organism or its spores were capable of withstanding the "chemic" and acid and subsequently developed under the influence of the warmth of the warehouse. As I can find no published reference to such an organism and the results of its growth are so remarkable and so liable to be mistaken, I think it desirable to put its existence on record.

Although pure cellulose is very stable and not readily attacked by micro-organisms, impure cotton is very liable to bacterial damage. It sometimes becomes evident in the form of spots, or colonies, or a diffuse growth; occasionally a chromogenic organism may entirely alter the colour of cotton goods. Bacterial growth often causes tendering of the cotton fibre and always, in the case of finished goods, destruction of the dress, frequently accompanied by the production of a musty odour. Cotton may become infected during bleaching and finishing at almost any stage, and when once infected, especially with a spore-forming organism, the subsequent processes are often not sufficiently drastic to kill the latter, which lie dormant till the goods are stored and then form a fresh growth. Thus, in the case mentioned above, the infection was proved to take place before the goods were bleached, and neither the bleach nor the acid had killed the spores.

The principal causes of infection are:—(1) Impure water for steeping and other processes. (2) Incomplete removal of nitrogenous constituents during soda boil. (3) Allowing goods to lie about in a damp condition between the processes. (4) The use of inferior materials in dressing, such as low grade starch and glue. (5) Careless storing of finished goods. (6) Insufficient cleanliness of plant and buildings.

Impure water.—Where suspicious or polluted surface or subsoil waters are used, mildew frequently results. This is particularly noticeable when polluted waters are used for making up finishing mixtures, since the heat employed is rarely sufficient to kill spores. The rapidity with which dressing mixtures sometimes "sour" is often traceable to this cause.

Incomplete soda boil.—Pentecost and I have previously emphasised the fact that the first and most important rule of successful bleaching is a thorough soda boil. An incomplete boil leaves not only greasy matters, which protect the fibre from the action of the chlorine, but nitrogenous bodies, which may subsequently cause trouble both directly and indirectly, in that they render the cotton more liable to bacterial infection. A great deal of scoured cotton contains as much as 0.3 per cent. of nitrogen, and in practically every case of bacterial infection that I have examined I have found a high nitrogen content in the cotton after removing the dress by fermenting or other means.

Careless handling between processes.—The danger of allowing moist goods to lie about, especially in warm weather, is often not sufficiently realised. It is a common cause of mildew.

The use of low-grade finishing materials.—In many cases price is the only factor which determines the selection of finishing materials, no regard being paid to quality. But in the selection of starches and glues quality should be the chief factor. All starches containing an undue proportion of water are liable to be mouldy when used, and those containing much nitrogen are also unsuitable for many purposes. Further, many thin starches, which are often essentially mixtures of starch and dextrin, contain as much as six per cent. of dextrose or other reducing sugars. This no doubt exercises a selective influence upon aerial organisms. At any rate goods dressed with such starches do not, in my experience, keep well. The following is an example of a thin starch used for goods which afterwards developed mould:—Water, 10-40 per cent.; dextrin, 20-00 per cent.; dextrose, 6-95 per cent.; starch, 62-40 per cent.; mineral matter, 0-25 per cent. Inferior glues, in a similar way, owing to the large amount of soluble nitrogen which they contain and the deliquescent nature

of the peptones, are very liable to become mouldy. It is very rare to find mould where a high grade glue has been employed. I give examples of good and bad glues, both used for cotton goods.

	Good.	Bad.
	per cent.	per cent.
Water	14.23	16.00
Ash	1.33	2.35
Gelatin	78.08	66.25
Peptones, etc.	1.95	11.42
Non-gelatinous bodies	4.41	3.98

Careless storing of finished goods is sometimes responsible for the development of bacterial growth. This is often noticed in those that are made for export to warm and damp climates. All cotton goods, however carefully prepared, contain numerous organisms, and the conditions of storing should always be such as will discourage their growth. Of course cleanliness is also an important factor. Occurrence of mouldiness is not infrequently found to be due to organisms indigenous to the customers premises, and does not recur after the application of sanitary precautions.

A NEW CHROMOGENIC ORGANISM.

BY S. R. TROTMAN, M.A., F.I.C.

I recently had occasion to examine some skivers which had developed a discolouration during drying. This varied from pinkish-brown to a distinct pink. An analysis of the skivers showed a slight excess of lime and a preponderance of soluble extractive matter in the damaged goods. As excess of lime is liable to produce harshness and brownish discolouration, there was some reason for supposing that this might be the cause, but this would not account for the increased extractive matter. This suggested a decomposition possibly resulting from bacterial growth. Cultures made from the pink skin showed the presence of two chromogenic organisms;

one of these proved to be a variety of pink torula which produces a reddish brown growth on gelatin media, but not identical with the ordinary pink torula. The second was a mould which forms a bright scarlet mycelium, and when sown on sound skins produces a colour which is identical with that observed on the damaged ones. On gelatin the colonies start as colourless or faintly pink spots, which gradually become darker till they have a bright red colour. After growing for about a week a number of colourless aerial hyphae are thrown up, the colour being confined to the mycelium, which forms a skin-like growth on the surface of the gelatin and gradually causes its liquefaction. I believe that no instance of such an organism has been hitherto recorded.

Journal and Patent Literature.

PATENT SPECIFICATIONS may be obtained by post by remitting as follows:—

English.—8d. each, to the Comptroller of the Patent Office, W. Temple Franks, Esq., Southampton Buildings, Chancery Lane, London, W.C.

United States.—1s. each, to the Secretary of the Society.

French.—1 fr. 25 c. each, to Belin et Cie., 56, Rue des Francs Bourgeois, Paris (3e.).

German.—1 mark each (with full particulars) to Kaiserlich Patentamt, Berlin, Germany.

I.—PLANT, APPARATUS, AND MACHINERY.

Magnesium chloride; Action of feed water containing — on the walls of steam boilers. A. E. Lange. Z. Ver. deutsch. Zuckerind., 1909, 1011—1019.

AFTER a brief account of earlier work on this subject, including that of Ost (this J., 1902, 1177), and that of Heyn and Bauer (this J., 1908, 569), the author describes experiments on the action of solutions of magnesium chloride at 100° C. alone, and in presence of different quantities of calcium carbonate, on iron. Polished iron plates, of equal areas, were used, and in most of the experiments the plates were wound with 2 turns of 1 mm. copper wire in order to approximate as closely as possible to the conditions which obtain in a boiler (i.e., iron in contact with copper). The plates were weighed, then immersed in the solution (maintained at a temperature of 100° C.) for 3 hours, and subsequently weighed again. In some comparative experiments, the plates were immersed in distilled water and in Berlin tap water. The main conclusions are as follows:—Iron is more strongly attacked by distilled water than by tap water. Magnesium chloride attacks iron in contact with copper more readily than iron alone; if an equivalent quantity of calcium carbonate is added to the magnesium chloride solution, the

extent to which the iron is attacked both in presence and in absence of copper, is reduced by more than 50 per cent. In absence of calcium carbonate, the passage of air through the solution of magnesium chloride, only slightly increases the action on iron; in presence of calcium carbonate (in quantity equivalent to the magnesium chloride), aeration considerably increases the action on iron; these two statements apply both when copper is present and when it is absent. A solution containing 5 grms. of magnesium chloride per litre attacks iron to about the same extent as tap water. The following are some of the figures showing the action of magnesium chloride on iron (copper being present in all cases) and the inhibitive influence of calcium carbonate on this action, the action of distilled water being represented by 100:—

5 grms. MgCl ₂ (per litre)	80.75
" " " + 1 eq. CaCO ₃	27.90

—L. E.

Volatile liquids lost in various industries; Recovery of — by cooling. G. Claude. Comptes rend., 1909, 149, 780—782.

IN order to recover volatile liquids, such as alcohol or ether, from air containing a small proportion of their vapours (such as is produced in the manufacture of Chardonnay silk, smokeless powder, celluloid, etc., the author proceeds as follows:—The air is subjected to a pressure of 4 atmospheres and passed through a water-cooled refrigerator where some water vapour is condensed; it then enters a multitubular condenser where it is gradually cooled until, at the top, the temperature is about -90°C . As the liquid first formed contains mostly water, that produced later is richer in the more volatile liquids, and the operation is so conducted that the liquid formed at any stage is not frozen. The air passing from the top of the apparatus is used again as a cooling medium. By this method it is possible to treat 20 cubic metres of air per horse-power-hour and to recover nine-tenths of the vapours present.—J. C. C.

PATENTS.

Subjecting gases or vapours to the action of liquids; Apparatus for — W. Feld. Hönningen-on-the-Rhine, Germany. Eng. Pat. 15,683, July 23, 1908.

THE claim is for improvements in the apparatus described in Eng. Pat. 11,206 of 1905; (this J., 1906, 838), and consists in providing horizontal or vertical perforated screens which are attached to and rotated by the vertical shaft which carries the spraying devices. The screens may be formed of perforated metal sheets, metallic gauze, or of a series of laths arranged like louvres. The object of the screens, through which both the gas and spray pass, is to facilitate the separation of the latter from the former.—W. H. C.

Pressing and straining animal and vegetable substances or other pulpy matter. S. G. Broadbent, Bradford. Eng. Pat. 22,150, Oct. 20, 1908.

THE claim is for improvements in presses having a cylindrical body, closed by a conical cover, and into which a conical ram is forced from below. The cylinder, cover, and ram-head are all perforated and covered with filter-cloth or other suitable filtering medium. The improvements consist in providing hollow chambers in the cylinder wall, cover, and ram-head into which the expressed liquid flows and from which it is discharged into appropriate receivers. One or more conical partition-plates may be arranged at suitable heights across the cylinder. These are hollow, and are perforated on their upper and lower surfaces and covered with filter-cloth. They serve to increase the ratio of the active filtering surface, the expressed liquid passing into the interior of the plate and being discharged from the edge into the perforations of the cylinder, whence it passes to the hollow chamber behind.—W. H. C.

Separating substances of different specific gravities and apparatus therefor. W. P. Thompson, Liverpool. From Badische Maschinenfabrik und Eisengiesserei vorm. G. Sebold und Sebold und Neff, Durlach, Germany. Eng. Pat. 1151, Jan. 16, 1909.

THE materials to be separated are fed into the drum, A, towards the lower end, by the pipe, H, and are washed by water fed through the pipe, G. The drum, A, is supported on the rollers, C, and by the bracket, E; it is rotated by the pulley, D, and is provided with an interior helical blade, B, which decreases in breadth from the lower to the upper end, as indicated at F, F, so that the turns of

the helix form settling pockets at the lower end of the drum. Provision may also be made for imparting to the drum a continuous or intermittent, vertical, horizontal or transversal shaking motion, this being effected by arranging the rollers which carry the upper end of the drum in a supporting ring resembling a "Cardan joint." The heavier material is carried upwards against the stream of water and is discharged from the upper end of the drum and the lighter portion is washed over the lower end of the helix.—W. H. C.

Filters; Automatic — A. James, London. Eng. Pat. 1315, Jan. 19, 1909.

THE claim is for improvements in the filters described in Eng. Pat. 11,623 of 1906 (this J., 1906, 989) and consists in arranging the rotating filter frames so that they are completely immersed in the pulp tank and that the vacuum is applied to both sides of the frame, with the result that filtration takes place on both faces simultaneously. Further, in order to facilitate the discharge of the cake, each frame is rotated during the introduction of the compressed air, the cake falling off from each filtering surface when it is facing downwards.—W. H. C.

Furnaces. Bell Bros., Ltd., and W. L. Johnson, Middlesbrough. Eng. Pat. 4123, Feb. 19, 1909.

THE fuel is fed by the plunger, s, from the hopper, r, into the upper end of the inclined conical furnace, formed of an outer metal casing, a, lined with refractory material, b, and provided with tapering projections, c, which lift up the fuel and drop it through the fire. The furnace is supported on rollers, a, a, and is rotated by the gear, m, n. The volatile portion of the fuel is burned off in the upper part of the furnace and the coked residue and ashes pass over the circular grate, f, through which any fine ash falls into the combustion chamber, g, where the coke is completely burned on the bars, j, by the aid of forced draught introduced through k. The ashes are removed through the doors, l, and the flame and hot gases pass through the fixed flue, e, into the tubes of the boiler. The furnace is designed to burn shale from coal washing plants and spoil heaps and other low-class fuels containing a high percentage of ash, which cannot be burned on ordinary grates.—W. H. C.

Barrels for oil and the like; Rendering liquid tight — [with waste sulphite pulp liquor]. B. Diamond, Idaweiche, Germany. Eng. Pat. 5206, March 3, 1909.

THE interior of the barrel is treated with waste sulphite pulp liquor resulting from the manufacture of cellulose from wood. The liquor should have a specific gravity of from 25° to 35°B , and is previously mixed with treacle, starch paste or water-glass.—W. H. C.

Evaporating apparatus. S. M. Lillie, Philadelphia, Pa. U.S. Pat. 939,143, Nov. 2, 1909.

THE apparatus consists of a shell divided by a vertical tube-plate into a steam chamber and an evaporating chamber. Horizontal tubes project from the steam chamber into the evaporating chamber, and the liquid to be evaporated is distributed over these tubes and over the vertical tube-plate by means of a perforated horizontal plate arranged above the tubes. The liquid is delivered on to this plate from a pipe running centrally across it, provided with two series of jets facing in opposite directions.—A. T. L.

Kilns. G. E. Snowden, New Cumberland, W. Va., U.S.A. Eng. Pat. 27,551, Dec. 18, 1908.

SEE U.S. Pat. 916,498 of 1909; this J., 1909, 465.—T. F. B.

Organic and inorganic bodies transparent and translucent; Process for rendering —. H. Streller, Leipzig, Germany. Eng. Pat. 8621, April 10, 1909. Under Int. Conv., April 11, 1908.

SEE Fr. Pat. 401 961 of 1909; this J., 1909, 1186.—T. F. B.

II.—FUEL, GAS, AND LIGHT.

Incandescence [electric] lamps; Total and monochromatic radiation of —. C. Féry and C. Chénaveau. Comptes rend., 1909, 149, 777-779.

By applying their experimental observations on the radiation of incandescence lamps with filaments of carbon and tungsten, to a mathematical expression connecting the absolute temperature of the filament with the number of watts expended, the authors find that the temperature (1780° C.) of a carbon filament is lower than that (1875° C.) of a tungsten filament. The specific yield of the tungsten filament is also greater (0.82 candle per watt) than that of a carbon filament (0.29 candle per watt). The latter observation confirms, from theoretical considerations on radiation, what is known in practical electric lighting.—J. C. C.

Development of the coal and iron industries. Greville Jones. See X.

PATENTS.

By-product retort coke-oven. H. Prentice, Bellevue, Pa. U.S. Pat. 939,086, Nov. 2, 1909.

THE walls separating adjacent coking chambers are provided with a series of separate horizontal combustion chambers arranged in pairs at different levels, each chamber having separate gas and air supplies. Between the two series of combustion chambers are arranged horizontal flues forming discharge passages for the burned gases, and alternately with these flues there are air heating flues, so that these latter are exposed at the top and bottom to the discharge flues and at the sides to the heating flues.—A. T. L.

Vertical retorts. R. Dempster and Sons, Ltd., and H. J. Toogood, Elland, Yorks. Eng. Pat. 28,201, Dec. 28, 1908.

VERTICAL retorts arranged in pairs or in rows are provided with a passage, controlled by a valve or seal, connecting the bottom-mouthpieces of two retorts which are charged alternately. The porosity of the charge varies during the process of coking, but by means of the connecting passage, the gas from the one retort can escape by way of the freshly charged retort in which the charge is more porous. The passage is closed by the valve, or seal, during charging. The invention is particularly applicable to retorts charged in the manner described in Eng. Pat. 19,437 of 1908 (this J., 1909, 1116).

—A. T. L.

Gas producer apparatus for the manufacture of gas suitable for heating and illuminating purposes. C. B. Tully, London. Eng. Pat. 22,851, Oct. 27, 1908.

THE patent relates to producers of the type in which a vertical retort for the decomposition of coal, tar, etc., is heated externally by the combustion of gas generated in a lower fuel chamber, there being separate air supplies to the gas generating chamber and to the combustion chamber for heating the retort. According to this invention, the valves controlling the two air supplies, the stack-valve, and a valve controlling the supply of steam to the lower part of the producer are inter-connected so that steam is admitted to the producer when the air valves and the stack-valve are closed, and to the stack-pipe when the air valves and the stack-valve are open.

—A. T. L.

Gas producers. C. B. Tully, London. Eng. Pat. 24,803, Nov. 18, 1908.

THE patent relates to producers of the kind in which liquid hydrocarbon is injected into a mass of incandescent fuel, the spraying nozzle being arranged beneath an arch which serves to keep a space in the neighbourhood of the nozzle free from fuel. In order to remove the carbon which is deposited on the incandescent fuel, a supply of air is admitted during the ordinary blowing of the producer through a louvre-like wall or grate arranged beneath the spraying nozzle and inclined inwards and downwards. The air chamber behind this wall is provided with an inspection-door and with a valved air inlet. A separate main valve controlling the supply to this air inlet may be inter-connected with other valves as described in Eng. Pat. 22,851 of 1908 (see preceding abstract), so that it is open when these other valves are set for blowing the producer to bring the fuel again to incandescence.

—A. T. L.

Peat-gas plant. J. D. Olinvy, Assignor to Peat Gas and Coal Co., Montreal. U.S. Pat. 938,691, Nov. 2, 1909.

THE apparatus comprises a horizontal retort-chamber mounted so as to rotate about its axis. The retort is provided with an axial air-inlet pipe leading from an air reservoir, and with an outlet pipe leading to a water-jacketed casing containing a carburetting chamber. The gas outlet from this casing leads through a series of condensing pipes to a gas-holder, and the casing is provided with a trapped overflow pipe for the tar.—A. T. L.

Peat and similar substances; Process and apparatus for the carbonisation of —. Oberbayerische Kokswerke u. Fabr. chem. Prod., A.-G. Ger. Pat. 213,852, May 6, 1908.

THREE gas-producers are used: the fresh peat is introduced into the first, wherein it is dried, and the steam produced is led into the third producer where it is converted into water-gas by means of the incandescent carbonised peat from the second producer. The second producer, fed with the dried peat from the first, is worked in the normal manner, the tarry and ammoniacal vapours being led away and condensed. A ring-pipe connected with all three producers is provided for collecting and distributing the steam.—A. S.

Gas; Apparatus for manufacturing —. B. Loomis, Hartford, Conn. U.S. Pat. 939,282, Nov. 9, 1909.

THE apparatus, which is designed for the manufacture of gas from moist materials, comprises a gas-producing chamber provided with a horizontal extension at its base. Above this horizontal extension, and opening into it, is a carbonising or distilling chamber, provided in its upper part with a vapour-outlet pipe leading to an air-condenser. The moist fuel is passed through a cutting apparatus and then fed to a "blower-elevator," which is supplied with heated air from the air-condenser. The current of air carries along the moist material, drying it in transit, and delivers it to a feed-hopper situated above the carbonising chamber.—A. S.

Gas-producer. Soc. Anon. des Houillères de Montrambert et de la Bérandière. Fr. Pat. 402,949, Sept. 12, 1908.

THE patent relates to a gas-producer with a rotating water-sealed ash-pit provided with a central vertical tuyère for the air-blast. The body of the producer is supported over the ash-pit on a polygonal framework of girders, two of the girders being extended in both directions so as to rest upon four short masonry columns. This arrangement allows of easy access to the ash-pit at all points. In order to break up the clinker, a number of rods or ploughs are provided, some being fixed to the body of the producer and others to the rotating ash-pit. The connection of the air main with the rotating tuyère is made by a water-sealed joint, excessive evaporation being prevented by heat-insulating packing between the air main and the water-lute.—A. T. L.

Gas-producer for fuels containing moisture and tarry substances. Soc. Genevoise pour la Construction d'Instruments de Physique et de Mécanique. Fr. Pat. 403,003, May 13, 1909. Under Int. Conv., June 4, 1908.

THE producer comprises an upper chamber in which the raw fuel is dried and deprived of its tarry constituents, and a lower gas-producer chamber into which the coked fuel descends. The fuel in the upper chamber is separated into two columns by a vertical partition, which may divide the chamber into two semi-cylindrical parts or into an inner cylinder and an outer annular space. One of these fuel columns is partly supported by a grate, beneath which air is admitted together with distillation products from the upper part of the chamber. This fuel column descends slowly, and is almost wholly burned in the upper part of the producer, thus serving to coke the raw fuel in the other column which can descend freely into the gas-producing chamber. This chamber is so arranged that any distillation products evolved in the upper part of it are mixed with the air-blast and injected into the lower part of the fuel column.—A. T. L.

Gas purifiers. R. J. Milbourn, Newport, Salop. Eng. Pat. 1630, Jan. 22, 1909.

THE patent relates to the valve arrangements of the purifiers described in Eng. Pat. H,356 of 1901 (this J., 1902, 599), the valves being arranged preferably outside the purifiers. The upper part of the purifier is fitted with a bend-pipe leading to a valved gas-outlet chamber and a long narrow opening in the lower part of the purifier is connected by a similarly shaped box or casing to a valved gas-inlet chamber. The gas-outlet and inlet chambers are arranged side by side with an opening in the dividing wall, and the gas outlet and inlet pipes are arranged with their open ends in line with this opening. A valve in each chamber is arranged so that it can be seated either on the opening in the dividing wall or on the end of the gas inlet or outlet pipe respectively.—A. T. L.

Incandescence gas mantles. V. B. Lewes. Fr. Pat. 403,195, May 21, 1909. Under Int. Conv., Jan. 22, 1909.

MANTLES composed of the oxides of aluminium and chromium, together with zirconium or thorium oxide give an agreeable light not so rich in violet and ultra-violet rays as is the ordinary thorium-cerium mantle, but these mantles cannot be used with upright burners on account of shrinkage and volatilisation in the hotter parts of the flame. The patent is for the use of such mantles with an inverted burner, which distributes the heat more evenly, and causes the weight of the mantle to counteract the tendency to shrinkage. A suitable composition is: aluminium oxide, 87 per cent.; zirconium oxide, 4 per cent.; chromium oxide, 9 per cent., but when thorium oxide is used, the composition may vary between the following limits: aluminium oxide, 48 to 60 per cent.; thorium oxide, 42 to 35 per cent.; chromium oxide, 5 to 10 per cent., and part of the thorium oxide may be replaced by zirconium oxide.—A. T. L.

Electric incandescence filaments of refractory metals or their alloys; Manufacture of non-carbon —. W. Heinrich, Charlottenburg, Germany. Eng. Pat. 7092, March 24, 1909.

A BINDING agent free from carbon is made by mixing 50 grms. of dry pure powdered sulphur with 60 grms. of dry amorphous phosphorus and heating the mixture until combination takes place. After cooling, a dark metallic shining liquid remains. 15 grms. of the powdered amorphous metal, for example tungsten are made into a paste with 3 grms. of the binding agent, and filaments formed from this paste are heated *in vacuo* to 400°–500° C., whereby most of the binding agent is expelled and a hard metal phosphide or sulphide compound is produced. The filaments are finally sintered and converted into the pure metal by heating *in vacuo* above 1000° C.—A. T. L.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

Hydrocarbons of the naphthene and benzene series; Oxidation of — by treatment with air in the presence of alkalis. K. W. Charitschkoff. Chem.-Zeit., 1909, 33, 1165. (See also this J., 1909, 302, 974.)

By the oxidation of petroleum hydrocarbons with air, using an alkali as contact substance, the author finds that characteristic acids are produced. These acids differ from the naphthenic acids in their solubility in petroleum spirit and in the characteristics of their esters and salts; they also possess reducing properties, though no evidence of the presence of an aldehyde group could be obtained. The purified acids are very unstable, and readily condense to tarry matters upon warming or by treating with strong alkali. A hydrocarbon ($C_{16}H_{26}$, b. pt. 169°–171° C.), yielded upon oxidation at 150° C. a syrup which, purified to remove the naphthenic acid also produced, gave an acid containing 73.8 per cent. of carbon and 7.73 per cent. of hydrogen. The analytical figures, and molecular weight determinations agree with the empirical formula, $C_{20}H_{25}O_4$. A polymerisation has thus taken place, hence the names "polynaphthenic" or "asphaltogenic," acids chosen for the series. All members contain four atoms of oxygen, two of which are alcoholic, though one of the alcohol groups apparently possesses a pseudo-acid character. The determination of the structure is difficult, as the constitution of the monobasic acid is not quite clear. The method of oxidation may be useful in the examination of naturally occurring hydrocarbons; benzene hydrocarbons yield crystalline monobasic acids, and the fact that it is the side chains which are attacked and oxidised and not oxygen which is absorbed, as in the case of naphthenes and olefines, is difficult to explain by Kekulé's hypothesis. The constitution of the acid derivatives of benzene is probably different, so far as the ring is concerned, from that of the hydrocarbon itself.—F. M.

Durene. R. Willstätter and H. Kubli. Ber., 1909, 42, 4151–4163.

WITH the object of preparing aminodurene the authors have endeavoured to prepare nitrodurene but without success. The action of nitric acid on the hydrocarbon always leads to the formation of the dinitro-derivative. Treatment of iododurene with silver nitrite gave only a very small amount of the mononitro-compound mixed with the iodo-compound, and nitration with the aid of benzoyl nitrate gave ω -nitrodurene, $C_6H_2(CH_3)_3CH_2NO_2$ (Pentamethylbenzene gave a mixture of nitro- and ω -nitro-derivatives and hexamethylbenzene gave, with 1 mol. of benzoyl nitrate, the ether of pentamethylbenzyl alcohol, and with 2 mols., ω -dinitrohexamethylbenzene). Aminodurene was finally obtained by nitrating bromodurene and reducing the bromonitrodurene with zinc dust and acetic and hydriodic acids. Aminodurene, $C_6H_4(CH_3)_3NH_2$, crystallises in prisms melting at 75° C. and boiling at 261°–262° C. It has a weak naphthylamine-

like odour and is oxidised to duroquinone without the formation of any product analogous to Emeraldine or Aniline Black.—J. C. C.

Petroleum deposits in Russian Sakhalin. Board of Trade J., Nov. 25, 1909. [T.R.]

THE three petroliferous areas so far known to exist in Russian Sakhalin are all on the east coast, and may be distinguished as (1) the Okha River oil-field, (2) the Boatasin and Nutovo oil-fields, and (3) the Nabil Bay oil-field.

(1) *Okha River oil-field*.—This area contains a large "petroleum lake" covered with a thick coat of asphaltum. The principal natural outcrops of petroleum in this area, including this large lake and another smaller one, are found in the Allas Valley, through which the Okha flows into Urkt Bay. The "petroleum lake" is close to the junction of this river with the Berakian. There are also many outcrops in lateral valleys known as Malaya and Ivanovskaya. They are in the form of holes full of water, on the top of which floats a deposit of petroleum some three inches thick, of heavy consistency and greenish-black in colour.

(2) *Boatasin and Nutovo River oil-fields*.—This area is the one to which most attention has been paid. In 1898 there were found, some eight miles from the mouth of the Nutovo river, a number of petroleum outcrops resembling those in the Allas Valley, and also five "petroleum lakes" of a similar nature to those on the Okha, the largest being 420 ft. by 1,400 ft. The "lakes" are, in reality, considerable areas covered with petroleum in a decomposed state, in parts liquid and in parts in the form of asphaltum. In 1901, boring operations were commenced on the Boatasin; two petroliferous layers, both in sand-stone, were discovered, the first at a depth of 150 ft. and the other at 237 ft. In 1906 several 14 ft. shafts were sunk in the Nutovo district, in all of which was found a thin crust of asphaltum above a layer of peat some 2 ft. in thickness and soaked with petroleum, which towards the top was continually changing from a greenish-black liquid state to a thick state, and, on the surface, was quite viscous and black. Under the layer of peat was sand strongly impregnated with petroleum, and below this again was sandy clay. The quantity of petroleum collecting in the shafts did not exceed 5 to 6 gallons in 24 hours. Abundant inflammable gases, mainly methane, issued from holes in the peat-lag in the region of the petroleum lakes.

Buildings are now being erected on these fields and systematic boring will commence on the arrival of new plant.

(3) *Nabil Bay oil-field*.—This area consists of (A) deposits on the Noglik River, a tributary of the Imtchin, which runs into the Timi River close to its mouth, and (B) deposits round the south-east corner of Nabil Bay. From a 26-ft. shaft sunk in the Noglik territory 8 to 10 gallons of heavy dark green petroleum were obtained in 24 hours, the specific gravity being 0.9 at 17.5° C.

The level of the petroliferous strata in the Nutovo deposits is probably a deep one in comparison with that of the Japanese oil-fields, the first deposits being at not less than 600 ft. and the second layer at about 2,000 ft. Sakhalin petroleum is rich in kerosene, containing probably 85 per cent. The oil will probably not play in fountains, but will require pumping.

Asphaltum; Analysis of — E. Bornemann, Chem., Zeit., 1909, 33, 1225—1226.

ASPHALTUM products which, on account of their sticky or tarry nature, cannot be pulverised in the ordinary manner, are moistened in an agate mortar with alcohol and thoroughly ground until reduced to a smooth, more or less stiff paste, alcohol or water being, if necessary, added during the operation. The mortar is then heated with occasional or constant stirring of the contents, until these are left in powder form. Drying is completed at 105°—110° C. The bitumen determination is made as follows:—In a small beaker 2 grms. of finely powdered asphaltum are moistened with 2 c.c. of alcohol and shaken with 10 c.c. of hydrochloric acid (sp. gr. 1.12). After about 10—15 minutes, when the evolution of carbon dioxide has ceased, 50 c.c. of water are added, the separated bitumen allowed to settle, and the supernatant liquor decanted through a filter (4 in. diameter and free from fat) on which about 1 gm. of very finely divided asbestos has been previously deposited from aqueous suspension. The bitumen is rinsed on to this, and the funnel, beaker, and glass rod used in filtering are dried for 1—1½ hours at 105°—110° C. The bitumen is now rinsed from the beaker and rod with about 75 c.c. of chloroform-alcohol mixture (10:2), the first portions running through being returned, if necessary, to the filter. The flask containing the solution is then attached to a Soxhlet apparatus, and the filter extracted in the usual way. If an asbestos filtering-tube be employed instead of filter paper, ½—1 gm. of finely divided asbestos must be added to the mass in the beaker to ensure perfect filtration. Various measures, which may be taken to accelerate the drying of the bitumen, are also mentioned. To obtain accurate results when determining the gypsum in crude asphaltum, the residue left after removal of the bitumen with chloroform must be exhausted with warm water and the extract added to the acid solution first obtained. In the determination of silica, etc., the asphaltum should be first incinerated until carbon is entirely removed, in order that pure and white silicic acid be subsequently obtained.—J. L. H.

Asphaltic material; Chemical examination of — S. W. Parr, B. Mears, and D. L. Weatherhead. J. Ind. Eng. Chem., 1909, 1, 751—754.

THE principle of the following method lies in obtaining as complete a solution as possible of the bitumen, and separating successive precipitates from this solution by the addition of other solvents:—0.5 gm. of the powdered sample (e.g., gilsonite) is dissolved in 5 c.c. of carbon bisulphide, and the solution treated with 100 c.c. of hexane (sp. gr. 0.6516). The precipitate (No. 1), which corresponds to the "asphaltene" of the usual methods, is filtered off into a Gooch crucible, after standing for 2 hours, and dried at 105° C. until constant in weight. The filtrate is evaporated to dryness on the water-bath, the residue taken up with 10 c.c. of hexane, and the solution poured, with continual stirring, into 300 c.c. of methyl alcohol. The resulting precipitate (No. 2) is collected and dried at 105° C. as before. The filtrate from the second precipitate is evaporated to dryness, and the residue (No. 3) dried and weighed. The following average results were thus obtained in the analysis of typical asphaltum products:—

Material.	Precipitate No. 1.	Precipitate No. 2.	Precipitate No. 3.	Total.
	per cent.	per cent.	per cent.	per cent.
I. Gilsonite, 4 samples	47.16	43.07	10.10	99.99
II. "Sarco petroleum," 8 samples	6.85	75.15	10.71	99.92
III. Mixture of I. and II. in equal parts (6)	28.71	33.38	17.97	100.06
IV. Mixture of I. and II. (1:3), 7 samples	18.28	64.61	17.22	99.96
V. Light cementing pitch (3)	18.82	40.20	22.19	81.22
VI. Mixture of I., II. and V. in equal parts	26.13	48.76	21.30	96.19
VII. Trinidad Lake asphaltum cement (5 samples)	18.43	33.39	22.20	100.10
				(including 27 per cent. insoluble in CS ₂ .)
VIII. Pure coal-tar pitch (2)	21.0	none	49.77	—

The precipitates (No. 1) were all solid at 105° C., with the exception of those from the coal-tar, which were viscous at the ordinary temperature, and fluid at 105° C. Precipitate No. 2 was sticky and soft at 105° C. in the case of gilsonite, and liquid in the other cases at that temperature, whilst precipitate No. 3 resembled machine oil except that it was more viscous. The mixtures showed the same general agreement in the divisions of the hydrocarbons as their components, and in the case of mixtures containing hard bitumen and tempering oil, the proportions of the latter could be approximately determined, provided that their percentage composition by this method of analysis were known. Loss of volatile substances in the melting process, however, would probably cause some discrepancy between the theoretical and actual results. The proportion of precipitate, No. 1, was found to stand in direct relationship to the sp. gr. of the precipitating solvent, and the preference was given to hexane as being more nearly constant in composition than the heavier petroleum distillates.—C. A. M.

PATENTS.

Tar; Treating — to recover certain light constituents, and to facilitate subsequent distillation. A. Gutensohn, London. Eng. Pat. 21,800, Oct. 15, 1908.

ONE hundred parts of an acid solution obtained by dissolving 1 part of chromic acid in 2 parts of water and adding 2 per cent. of concentrated sulphuric acid, are placed in a suitable closed vessel provided with an agitator and connected to a condenser. Two-thirds of the weight of gas-tar are added and the heat evolved is said to be sufficient to vaporise the lighter constituents of the tar, which pass into the condenser and are recovered. The solution is then drawn off and the heavier oils distilled off from the residue in the usual manner, but it is claimed that this can be effected at a lower temperature than that which is necessary with untreated tar and that no trouble from boiling over is to be anticipated. In order to obtain pitch of the right quality, the distillation is stopped when yellow fumes make their appearance. It is claimed that the pitch obtained from treated tar is more valuable than that from untreated tar and that it is more elastic.—W. H. C.

Liquids [tar]; Process for the evaporation of —. Apparatebau-Ges. "Köln." Ger. Pat. 215,005, Oct. 8, 1908.

In this process, which is specially suitable for the distillation of tar, the vapours evolved are passed through a superheater and then again brought in contact with the tar which is being distilled. The apparatus used is shown in the accompanying diagram. The tar is forced by the pump, A, through the coil, B, disposed in the cooler part of the furnace. The hot tar flows from the upper end of the coil, B, into the vessel, C, and overflows as shown. The vapours, or a portion of them, pass through the superheater, D, and then enter the lower part of the wide pipe, H, up which they rise, meeting the descending hot tar. The vapours pass away finally through the pipe, E, to the condensing apparatus.—A. S.

Ammoniacal liquor; Extraction of ammonia from —. M. Herry. Fr. Pat. 403,956, May 14, 1909.

THE liquor, separated from tar, is treated with a current of carbon dioxide in order to convert ammonium sulphides into carbonate. Sodium carbonate is then added in order to decompose cyanides, thiocyanates, etc., and the liquor is concentrated. The concentrated liquor can be used for the production of ammonium carbonate crystals, or the ammoniacal vapours can be mixed with the crude gas from the retorts in order to form ammonium sulphide, carbonate, thiocyanate, etc., which can be removed by washing, thus purifying the gas without the use of iron oxide.—A. T. L.

IV.—COLOURING MATTERS AND DYESTUFFS.

Indian indigo crop. Chem. Trade J., Nov. 13, 1909. [T.R.]

THE First General Memorandum on the indigo crop of the season 1909-10, issued by the Commercial Intelligence Department of India, says that the average area under the crop in the last five years was 487,200 acres; but in 1908-9 the total acreage was only 237,600 acres (revised figures). The area now reported for 1909-10 amounts to 214,600 acres. The figures in brackets following the name of each province, indicate what percentage of the total indigo area of British India is ordinarily cultivated in that province.

Bengal (37.1 per cent.).—The area sown this year is estimated at 107,700 acres as compared with 135,300 acres last year. The season has been unfavourable. The average outturn for the province as a whole is estimated at 70 per cent. of the normal as compared with 73 per cent. last year. [Normal=20 lb. per acre.]

Madras (33.7 per cent.) reports the total area sown in *raiayatwari* villages up to the end of August to be 41,900 acres, which is 24 per cent. more than the area sown in the corresponding period of last year. The increase is mainly attributed to timely rains. The area reported from villages other than *raiayatwari* is 1,300 acres as compared with 1,700 acres last year. The condition of the crop fair to good.

United provinces (16.7 per cent.).—The total area sown is at present estimated at 31,500 acres compared with 30,700 acres last year. Germination was good. For the province as a whole the yield is estimated at 80 per cent. of the normal compared with 85 per cent. last year. [Normal=18 lb. per acre.]

Panjab (10.8 per cent.) estimates the area sown to be 32,200 acres as against 36,200 acres last year. The decrease is confined to Multan, and is due to a short supply of water in the canals at sowing time and to the presence of locusts.

Indigo; Action of primary amines on —. (Addendum to Part I.) E. Grandmougin. Ber., 1909, 42, 4218. (Compare this J., 1909, 1189.)

7:7'-Dimethylindigo can be characterised by its spectroscopic behaviour. It dissolves in xylene with a violet blue colour: the dilute solution shows an absorption band at $\lambda=603.8$, whilst the corresponding band in the case of indigo is at $\lambda=591.4$. In glacial acetic acid the bands are: Indigo, $\lambda=615.9$, and dimethylindigo, $\lambda=617.7$.—J. C. C.

Indigo; Mechanism of formation of — from anthranilic acid and polyhydroxy-compounds. A new synthesis of indigo. Preliminary communication. I. Ostromisslenski and A. Pamfilow. J. Russ. Phys.-Chem. Ges., 1909, 41, 784-789. Chem. Zentr., 1909, 2, 1749-1750.

STARTING from the fact that hydroxy-derivatives of hydrocarbons are converted into carboxylic derivatives when fused with alkalis at high temperatures, the authors represent the formation of indigo on heating anthranilic acid with potassium hydroxide and glycerol or other polyhydroxy-compounds by the following scheme:—

Aniline Black.	Formula.	Base.	Salts.	Base with sulphur dioxide.	Solution in sulphuric acid.
Triquinonoid	$C_{48}H_{36}N_8$	dark blue	green	becomes bright green	reddish violet
Tetraquinonoid	$C_{48}H_{34}N_8$	blue black	dark green	very dark green	
Hydrolysed triquinonoid	$C_{48}H_{36}ON_7$	bluish dull black	greenish black	greenish black	bluer shade of violet
Hydrolysed tetraquinonoid	$C_{48}H_{34}ON_7$	dull black	dull black	remains black	

If aldehydes are used in place of glycerol, the reaction follows a similar course, except that Schiff's bases are first formed:—

The production of indigo in a similar manner on heating a mixture of o-naminobenzylalcohol, glycerol, and potassium hydroxide to 200°-300° C. is well suited for a lecture experiment.—A. S.

Dimethylaniline-isatines; Oxidation of —. N. Danaila. Comptes rend., 1909, 149, 793-795.

DIMETHYLANILINEISATINE and its substituted derivatives of the general formula,

where X = Cl, Br, NO₂, and X₂ = Cl₂, Br₂, when oxidised with lead peroxide in presence of acetic acid, yield dyestuffs analogous to Malachite Green. The author considers that these dyestuffs are most probably represented by the formula,

Aniline Black. R. Willstätter and S. Dorogi. Ber., 1909, 42, 4118-4135. (Compare this J., 1909, 695).

THE authors distinguish the various forms of Aniline Black as follows: (1) Triquinonoid Black (i.e. the formula contains three quinonoid groupings) obtained by the action of bichromate on excess of aniline solution, also by using elderate and persulphate as oxidising agents, has the formula, C₄₈H₃₆N₈. (2) Tetraquinonoid Black obtained by further oxidation of the preceding with hydrogen peroxide, by the action of excess of oxidising agents on aniline, in which process is included that of A. G. Green (oxidation of aniline salt in presence of copper sulphate and a little p-phenylenediamine by air) and also oxidation with chloric acid. Willstätter and Moore's "Polymerisation Black" also consists of this variety. All these different preparations of oxidised Black are almost quantitatively oxidised to p-benzoquinone; they all lose one-eighth of their nitrogen as ammonia (showing that the molecule contains C₄₈); and they combine with 4.5 per cent. of hydrogen chloride, indicating the reacting fourth quinonoid nucleus. When the triquinonoid Black is hydrolysed and then treated with hydrogen peroxide, it yields the same tetraquinonoid oxy-compound as does the tetraquinonoid Black when hydrolysed. The colour reactions of these compounds are as follows:—

The hydrolysed compounds can be more easily obtained by employing an excess of strong oxidising agents. The authors are of the opinion that Emeraldine consists of the triquinonoid Black and suggest that the name be now used to denote the polymeride of phenylquinonedi-imine of the formula,

With regard to the technical production of Aniline Black on the fibre, the steaming and other processes which are necessary to obtain an ungreenable Black, result in the production of the hydrolysed tetraquinonoid Black. —J. C. C.

Quinonedi-imines; Polymerisation of —. R. Willstätter and H. Kubli. Ber., 1909, 42, 4135-4151.

WITH the object of throwing light on the constitution of Willstätter and Moore's Emeraldine, the authors have studied the polymerisation of para-substituted phenylquinone-di-imines, in particular quinonetolyl-di-imine, CH₃·C₆H₄·N:C₆H₄:NH, and the corresponding anisyl compound. Although phenylquinonedi-imine polymerises readily to the dimolecular Emeraldine, the para-substituted derivatives polymerise only with difficulty and then a trimolecular imine is formed which differs considerably from Emeraldine. A corresponding trimolecular imine, can be prepared from phenylquinonedi-imine itself when it is subjected to the same method of condensation, namely, passing hydrogen chloride through the solution of the imine in methyl alcohol. Oxidation experiments lead to the conclusion that the unsubstituted trimolecular polymeride has the constitution,

and the corresponding methyl derivative the constitution,

Willstätter and Moore's "red imine" has probably the constitution, $\text{C}_6\text{H}_3 \cdot \text{N} : \text{C}_6\text{H}_4 \cdot \text{N} \cdot \text{C}_6\text{H}_4 \cdot \text{N} : \text{C}_6\text{H}_4 \cdot \text{O}$. This conclusion is confirmed by the fact that its methyl homologue is obtained by oxidising the leuco-base prepared by oxidising equimolecular proportions of *p*-hydroxydiphenylamine and *p*-aminophenyl-*p*-tolylamine with hydrogen peroxide. It forms brick red crystals melting at 205°–206°C. A corresponding red imine containing the methoxy-group, $\text{CH}_3 \cdot \text{O} \cdot \text{C}_6\text{H}_3 \cdot \text{N} : \text{C}_6\text{H}_4 \cdot \text{N} : \text{C}_6\text{H}_4 \cdot \text{O}$, was also prepared in an analogous manner.—J. C. C.

Flaveosine. E. Grandmougin and A. Lang. Ber., 1909, 42, 4014–4019.

THE authors have prepared Flaveosine as follows:—diethyl-*m*-phenylenediamine is acetylated by heating the base (10 grms.) with glacial acetic acid (12 grms.) and a few drops of acetic anhydride for 7 hours. The mono-acetyl derivative thus produced (9.1 parts), is heated with phthalic anhydride (3.3 parts), and acetic anhydride (2.25 parts) for 5 hours at 150°C., whereby diacetyl-diaminodiethylanilinephthalein,

is obtained. When this is boiled with 20 parts of 20 per cent. hydrochloric acid, Flaveosine is obtained in orange yellow needles, m.pt. 333°C. Its constitution is therefore proved to be represented by the formula,

Flaveosine dissolves readily in methyl and ethyl alcohols, in acetic acid and acetone; the solutions exhibit a green fluorescence. It is less soluble in benzene, ethyl acetate, chloroform or carbon tetrachloride and insoluble in ether and light petroleum. The solution in sulphuric acid is bright yellow with a blue-green fluorescence; on dilution, a deep red solution with a faint brown fluorescence is obtained which, on further dilution, becomes yellowish orange with a green fluorescence. The ethyl ester, on bromination, gives a red tetrabromo-derivative. The corresponding dyestuff containing methyl groups instead of the ethyl groups of Flaveosine, was prepared in an analogous manner; it dyes silk yellow with a green fluorescence, and yields a tetrabromo-derivative.—J. C. C.

Fastness to light of some coal tar colour lakes, and their behaviour as printing colours. E. Valenta. Chem.-Zeit., 1909, 33, 1165–1167.

THE belief that all the artificial dyestuffs are much more fugitive to light than the natural ones is quite without foundation, and arose through the manufacturers being led by the brilliance of the shades to use the dyestuffs for purposes for which they were unsuited. At first some of the Alizarin colours alone combined brilliancy with a high degree of fastness, but now there are many products which, for colour lakes, will fulfil all requirements in these respects, for example, the Azophor colours, the Azarines, Lithol Red, Permanent Red, Pigment Scarlet, etc.; also within the last few years many new dyestuffs have been produced of such properties that no complaint as to want of fastness can be substantiated. In comparative trials, the author employed as standard the alumina-oil lake of Alizarin (Turkey Red), and found that lakes prepared with some of the newer dyestuffs show a much greater degree of fastness even than this. He reports upon the

fastness of some 43 colour lakes (15 red, 10 yellow and orange, 4 green, and 14 blue and violet), giving the class to which each dyestuff belongs, the method of preparation of the lake and the printing paste, the method of exposure, and the results thereof, and certain other interesting data. Among the red colouring matters the lakes of Helio Fast Red RL and Helio Fast Pink RL (By.) are of much superior fastness to Alizarin, and Alizarin Red 1 B Paste Extra, Pigment Fast Red HL and Alizarin Red RX Paste (M.L.B.) are quite equal to it. Helio Fast Yellows 6 GL and GL (By.) are of much greater fastness than the standard, and with the highly resistant and brilliant Helio Fast Blue B (By.) must give very fast shades of green. Helio Fast Violet (By.), Alizarin Direct Violet (M.L.B.) and the Orthocyanines (Berlin) are also exceedingly fast. Very interesting is the behaviour of the Ethyl Green lake. This lake is prepared by precipitation (fixation) of Brilliant Green (a fugitive colour) with "green earth;" and was found, as a printing colour, to be much faster than many of the other greens tested.—F. M.

Capillary rise of dyestuffs. L. Pelet-Jolivet. Z. Chem. Ind. Kolloide, 1909, 5, 238–243.

THE author reported recently (this J., 1909, 85) on the capillary rise of dyestuffs in filter-paper. The present results were obtained with strips of linen, wool, and silk. As in former cases, the rise was found to be small when the affinity of the dyestuff for the material of the strip was small. The colour-bases show a medium rise, which is generally smaller than that of the colour-acids. The Rhodamines show an intermediate behaviour. The difference between colour-bases containing the amino-group and those containing a disubstituted amino-group is similar to that observed on cellulose fibre (*loc. cit.*). In general, dyestuffs of colloidal character ascend a shorter distance than the more crystalline dyestuffs of similar composition. The influence of electrolytes was investigated and was of the same kind as when cellulose was used. Increase of temperature appears to lessen the capillary rise. Solutions in alcohol and acetone showed considerable rise, but no separation of dyestuff and solvent, pointing to very weak adsorption. Other things being equal, the addition of an electrolyte causes a tendency to diminution of the charge on a phase boundary, coagulation of a colloid, increased adsorption in dyeing processes, and diminution of capillary rise.—E. F.

PATENTS.

Colouring matters [dyestuffs] of the pyrazolone group; Manufacture of —. J. Y. Johnson, London. From Badische Anilin und Soda Fabrik, Ludwigshafen, Germany. Eng. Pat. 1244, Jan. 18, 1909.

GREENISH yellow dyestuffs fast to light are obtained (1) by combining two molecular proportions of the hydrazine of 3-chloro-2-amino-1-methylbenzene-5-sulphonic acid with dihydroxytartaric acid; (2) by combining one molecular proportion of the above hydrazine with oxalyl-acetic ester to form a pyrazolone, saponifying, and acting on the resulting product with one molecular proportion of the diazo derivative of the first-mentioned sulphonic acid. —J. L. H.

Hexabromindigo; Manufacture of greenish-blue —. O. Imay, London. From Farbwerke vorm. Meister, Lucius und Brüning, Hoechst a/M., Germany. Eng. Pat. 2609, Feb. 3, 1909.

ALTHOUGH the statement has been made that by the direct bromination of indigo or of dibromo-indigo, no higher derivative than tetrabromo-indigo can be obtained, it is now found that penta- and even hexa-bromo-indigo is obtained when suitable conditions are chosen. Such conditions consist in the use of excess of bromine, raised temperature, a longer period of treatment, or more highly concentrated sulphuric acid. Several examples of the method of working are given. The hexa-bromo-indigo produced, dyes in the vat clear greenish-blue tints, and differs in constitution and properties from the hexahaloindigo produced by the bromination of *p,p*-dichloro-indigo.—F. M.

[Azo] dyestuffs which can be developed; Process for preparing —. Farbwerke vorm. Meister, Lucius, und Brüning. Ger. Pat. 214,798, April 3, 1908. Addition to Ger. Pat. 208,968, March 29, 1908 (see this J., 1909, 517).

DIAZOTISED mononitrobenzoylated diamines are combined with nitroarylacidyl-2,5,7-aminonaphtholsulphonic acids, and the dinitro-azo dyestuffs reduced to the corresponding diamino-compounds. The dyestuffs dye unmordanted cotton red shades, which are rendered fast to washing and "bleeding" by diazotisation and development with β -naphthol. An example is given in which diazotised *p*-nitrobenzoyl-*p*-phenylenediamine is combined with *m*-nitrobenzoyl-2,5,7-aminonaphtholsulphonic acid.

—T. F. B.

1-Aminonaphthalene-4,7-disulphonic acid and 1-aminonaphthalene-2,4,7-trisulphonic acid from 1,8-dinitronaphthalene; Process for preparing —. Farbwerke vorm. Meister, Lucius, und Brüning. Ger. Pat. 215,338, Oct. 7, 1908.

1,8-DINITRONAPHTHALENE is treated with solutions of sulphites (e.g., about 40 per cent. strength), at 70°–90° C., for 6 to 8 hours, using about 6 mols. of sulphite to each molecule of dinitronaphthalene; in this way 3 mols. of free alkali hydroxide are formed, which must be neutralised or otherwise removed, or formation of yellow products will result; this can be accomplished by addition of mineral or organic acids, or by passing carbon dioxide through the liquid, or by addition of a bisulphite or bicarbonate, to keep the solution neutral or very slightly alkaline; or, if desired, ammonium salts may be added to the sulphite. When the solution is clear, it is cooled, and the crystals of 1-naphthylsulphamine-4,7-disulphonic acid separated, and converted by dilute mineral acid into 1-naphthylamine-4,7-disulphonic acid. The mother liquor is treated with mineral acid, and the mixture of naphthylamine-di- and trisulphonic acids separated by fractional crystallisation.

—T. F. B.

Dyestuffs for animal fibres and processes for obtaining them. H. R. Vidal. First Addition, dated Aug. 29, 1908, to Fr. Pat. 391,465, Aug. 29, 1907.

The dyestuffs described in the main patent (see this J., 1908, 1150) may be obtained by effecting the oxidation in an alkaline instead of in a neutral solution. In presence of alkali, the reactions proceed more smoothly. The dyeings may be rendered faster by after-treatment with formaldehyde. The dyestuffs may also be used for the preparation of sulphide dyestuffs.—A. S.

Cellulose threads, ribbons, films and the like; Production of —. P. Friedrich, Berlin. Eng. Pat. 11,700, May 18, 1909.

INSTEAD of precipitating the euprammonium cellulose solution with acids, alkalis, or alkalis and solutions of chlorides of the alkalis or alkaline earths, it is proposed to employ solutions of certain chlorides (calcium, magnesium, aluminium). The bath should be maintained in a slightly acid condition and organic substances such as alcohols and carbohydrates may be added to it with advantage. The threads obtained are said to be highly elastic and transparent, and possessed of good strength immediately after coagulation.—F. M.

Hygroscopic wadding; Process of manufacture of —. E. Nowicki. Fr. Pat. 402,196, Apr. 19, 1909.

THE use of fibres of flax and hemp is claimed for the manufacture of absorbent wadding. These fibres are brought into a suitable condition by steeping for one day in a 1 per cent. solution of sulphuric acid, or for a shorter time in the heated acid. The usual treatment with alkalis is also specified for the purpose of dissolving the incrusting matters and separating the bundles of fibres into their ultimate units.—J. F. B.

Silk-finish and other similar effects on textile goods; Process for preserving the —. F. A. Bernhardt, Zittau, Germany. Eng. Pat. 20,728, Sept. 10, 1909. Under Int. Conv., July 17, 1909.

SILK or Schreiner finishes are said to be made permanent and fast to water by spraying on the finished fabrics a solution of caoutchouc or resin and paraffin wax in benzene or similar volatile solvent, e.g., 30 grms. of caoutchouc and 7 grms. of paraffin wax in 1 litre of benzene. The solution may be applied once, or (better) several times, in such a manner that a thin layer protecting the convex upper parts of the ribs is formed, without filling-up of the depressions between the ribs. The treated material is dried, or dried and steamed, after each application.—J. L. H.

Vat dyeings; Production of fast grey prints and —. O. Inray, London. From Society of Chem. Ind., Basle, Switzerland. Eng. Pat. 20,312, Sept. 4, 1909.

VAT dyestuffs which dye animal and vegetable fibres in violet to blue shades are obtained by treating the dyestuff of the constitution,

with halogens. Dyeings obtained with the mono-halogen derivatives are blue in colour and are converted into grey shades (very fast to washing, light, and chlorine), by treating with hot water, with or without the addition of soap, alkali, acid, salts or bichromate.—F. M.

Impregnating fabrics and other materials; Apparatus for —. E. W. Strohn. Buffalo, N.Y. U.S. Pat. 937,889. Oct. 26, 1909.

THE impregnating chamber is provided with front and rear doors, and with a tank for the impregnating liquid which may be removed from the chamber through the front door. A delivery drum containing the material to be impregnated is arranged in the tank, and a receiving drum for the material is placed in the upper portion of the chamber, this drum being removable through the rear door. Two pairs of pressure rolls are mounted in the chamber between the delivery and receiving drums for acting upon the material, and means are provided for raising and lowering the pressure rolls. The first rolls, after lowering, dip into and apply the liquid to the fabric, whilst the others squeeze the impregnated fabric.

—B. N.

Hank dyeing; Continuous process of —. J. and L. Regordosa Planas. Fr. Pat. 401,988, April 13, 1909.

IN the type of continuous machine where the hanks are suspended on carriers supported at either end by driven chains, the hanks are subjected to a rapid to and fro motion at the surface of the bath and an up and down motion in the bath, the object being to secure better penetration. The to and fro motion is effected by two horizontal rollers or rods placed respectively in front of and behind the descending rows of hanks and connected to the same supports, which latter are driven rapidly backwards and forwards. The motion in the bath is obtained by passing the rows of hanks as they come round over a horizontal roller which is driven rapidly up and down.

—H. P. P.

Impregnation of vegetable fibres; Process for the rapid —. P. Hoffmann and E. Decoster. Fr. Pat. 402,041, April 15, 1909.

To obviate the processes of boiling or degumming fibres before bleaching or dyeing, there are added to the dye-bath or to an impregnating bath before bleaching, from 5 to 10 grms. of an aromatic phenol, for instance, the rectified carboic acid obtained from coal-tar. The phenol or mixture of phenols is used preferably in the form of the monosulphonic derivatives or their alkali salts. On account of the penetrating odour attending their use, it is preferable to close in the vessels in which the treatment is effected. The odour disappears completely from the fibres, however, on drying. It is claimed that the above addition insures an immediate impregnation even in the cold.—H. P. P.

Washing linen and the like; Method of —. J. Mehne, Leipzig-Plagwitz, Germany. Eng. Pat. 7619, March 30, 1909.

SEE Fr. Pat. 401,211 of 1909; this J., 1909, 1084.—T. F. B.

VII.—ACIDS, ALKALIS, SALTS, AND NON-METALLIC ELEMENTS.

Sulphurous acid in the gas from sulphur furnaces; Determination of —. H. Pellet. Bull. Assoc. Chim. Sucr. et Dist., 1909, 27, 294-302.

SAILLARD and Wehrung (supplement to the "Circulaire du Syndicat des Fabricants de Sucre de France, Sept. 26, 1909), have described a method for determining sulphurous and sulphuric acids in sulphur burner gases which is essentially as follows:—A conical flask of known capacity is filled with the gases, at a temperature of 15° C., and a known volume of a standard solution of sodium hydroxide is then introduced to absorb the sulphur dioxide and trioxide. When absorption is complete, two aliquot portions of the solution are removed; one is used for determining the residual alkalinity, whilst the other is rendered almost neutral and then titrated with N/10 iodine solution. From the results, the percentages of sulphur dioxide and trioxide can be calculated. A Bunte burette may be used for collecting the sample of gas instead of a conical flask, but the latter is preferable.

—L. E.

Boric acid; Solubility and hydrates of —. R. Nasini and I. Ageno. Z. physikal. Chem., 1909, 69, 482-485.

IN view of the conflicting statements as to the solubility of loric acid, the authors have carried out a new series of determinations at different temperatures between 0° and 120°C. The results obtained were as follows, the figures representing grams of loric acid (H_3BO_3) in 100 grms. of solution: 0°C., 2.59; 12.5°, 3.69; 21°, 4.90; 31°, 6.44; 40°, 8.02; 50°, 10.35; 60°, 12.90; 69.5°, 15.58; 80°, 19.11; 90°, 23.30; 99.5°, 28.10; 108°, 36.7; 115°, 45.0; and 120°C., 52.4. At higher temperatures the loric acid had a considerable action on glass, and concordant results could not be obtained.

A dilatometric study of the transformations of loric acid proved the existence of transformation points at 107°—108° C. and 138°—140° C., corresponding to the formation of metaboric acid and pyroboric acid respectively. No indication was obtained of the existence of other hydrates than these.—A. S.

The German Potash Syndicate. U.S. Cons. Repts., Nov., 1909.

OWING to the extensive area of the potash fields, new mining companies are established every year. When the competition of these companies becomes acute they are admitted into the syndicate. At recent meetings of the syndicate a number of new companies were admitted. Then arose a dissension as to the allowance to be made to each of the old companies, some of which had concluded contracts with American customers (this J., 1909, 833). There are two groups of these mines, one the Schmidtman group, consisting of the Aschersleben and of the Sollstedt Mining Works, representing what is called the North Trust and also the International Agricultural Co. in the United States, and the Einigkeit Mining Works, with those of Westeregeln and Salzdetfurth, representing what is called the South Trust in the same country. On Sept. 30, the proposition of the Schmidtman group for the syndicate to take over certain contracts with American companies for the delivery of 54,000 tons of pure potassium salts at half the prevailing price was rejected and the syndicate broke up. The Schmidtman group and the Einigkeit Mining Works withdrew. Westeregeln and Salzdetfurth mines, which had hitherto acted in concert with Einigkeit, remained with the other mines, numbering about 50. These

resolved to form themselves into a new syndicate. At first, an attempt was made to coerce the recalcitrant members of the syndicate by the threat of an export duty on potassium salts. These responded that the American government would retaliate and that such a duty would only injure the syndicate by driving away the best customers it had. As this policy failed, it is now intended to bring the dissenting mines into subjection by under-selling.

The Schmidtmann group has made contracts with the North Trust and with the International Agricultural Co. for two years for the delivery of 54,000 tons of salts at half the present syndicate prices. As these prices are fixed on, this group expects to hold its own, even if the fighting syndicate should reduce the price of one double centner (220.46 lb.) of potassium chloride to 5 marks. On the other hand, the trusts are bound by their contracts for at least two years at the price fixed, and are exposed to the competition of outside parties, who purchase from the syndicate at lower prices. American dealers do not sell potassium salts, but mixed fertilisers, and it is upon this market that the battle must be fought out. It is a question whether the fighting syndicate will be able to supply sufficient mixed fertilisers to the market so as to attract the trade. Since the two mines, Westeregeln and Salzdetfurth, have broken off relations with the Einigkeit mine, it is claimed that the South Trust will not be able to supply its demand without the help of the syndicate. There are also the former customers of the Sollstedt mine, whose contracts were taken over by the old syndicate. The plan has been proposed to supply these parties with salts at very reduced prices, which the clauses of their contracts admit, and then give the contracts back to the Sollstedt mine, which, under their original contract with the syndicate, it would now be compelled to carry out.

The German Kali Works, the American representatives of the German Potash Syndicate, has now been incorporated under the Laws of the State of New York with a capital of \$100,000 fully paid, and will deal direct with the fertiliser factories outside of the three corporations controlling a large portion of the American trade.

Gypsum in Nova Scotia. Oil, Paint, and Drug Rep., Nov. 1909. [T.R.]

CONSUL JOHN E. KEHL furnishes the following information concerning the new deposits of gypsum which are said to exist near Sydney, Nova Scotia:—

A local railway company has acquired considerable land at East Bay, about 15 miles from Sydney, which is said to contain inexhaustible deposits of gypsum. The whole extent of the company's present holdings and a large section round about appear to abound with the material. The deposit is being thoroughly exploited by the present owners, with the assistance of government experts. A calyx drill was used to ascertain the depth of the plaster; the drill was operated at the base of the face of a hill, and driven down about 80 ft.; no break was found in the deposit. The analysis, straight through, shows nearly 99 per cent. of purity. Some 20 tests have been made, and it is claimed that in every instance the pure gypsum has been found at an average of 10 to 12 ft. beneath the surface. Tide water with excellent shipping accommodations is less than three miles distant, and a Bill is now before the Nova Scotia legislature for the construction of a line of railway from East Bay to Sydney.

Nitrites; Analysis of — A. Sanin. J. Russ. Phys.-Chem. Ges., 1909, 41, 791-795. Chem. Zentr., 1909, 2, 1773.

THE method proposed depends upon the interaction of nitrites with hydroxylamine hydrochloride, in accordance with the equation:

About 5 grms. of the nitrite are dissolved in 1 litre of water, and 20 c.c. of the solution are warmed for 5-8 minutes with 20 c.c. of a standardised solution of hydroxylamine hydrochloride (about 10 grms. per litre) until

evolution of gas ceases. Then, after cooling, the excess of hydroxylamine hydrochloride is titrated with $\text{N}/20$ sodium hydroxide solution, using phenolphthalein as indicator.—A. S.

Water-glass solution; Influence of calcium carbonate on — O. Kallauner. Chem.-Zeit., 1909, 33, 1174-1175.

THE hardening of mixtures of calcium carbonate and water-glass on exposure to the air is found to be accompanied by absorption of atmospheric carbon dioxide and considerable loss of water; very little calcium silicate is formed. Hardening commences at the surface of the material, and the interior tends to remain soft; its principal cause is considered to be the separation of gelatinous silica, due to the influence of carbon dioxide and loss of water, the carbonate being practically inert. Strontium and barium carbonates behave like the calcium compound.—F. SODN.

Calcium cyanamide; Formation of — F. Foerster and H. Jacoby. Z. Elektrochem., 1909, 15, 820-834.

PREVIOUS work on the influence of calcium chloride and calcium fluoride on the formation of cyanamide from calcium carbide (this J., 1907, 423) has been extended. Rudolf's view that the efficacy of added salts is greatest at temperatures just above their melting points (this J., 1907, 822) is not confirmed. Although the addition of calcium fluoride affects the speed of the reaction, it does not alter the state of final equilibrium, which, for a given temperature, reaches the same point, whatever the amount of fluoride added. Under otherwise uniform conditions, the rate at which carbide, mixed with calcium fluoride, is transformed into cyanamide is proportional to the pressure of the free nitrogen. Larger quantities of material being used than in former experiments, it has been established that with carbide alone or with mixtures of carbide and calcium chloride, the temperature of the mass rises very considerably during the reaction, though further heating is necessary to make the absorption of nitrogen at all complete. With calcium fluoride, on the other hand, a much more uniform rate of reaction may be maintained at a lower temperature, and the total time required for complete absorption is no greater than when calcium chloride is used. Similar results have been obtained on the large scale by F. Carlsoo, who finds that with an addition of 10 per cent. of calcium chloride the temperature of the mass in the retort rises to 1000°C ., although, in the presence of the chloride, 800°C . would be a sufficiently high temperature for the rapid absorption of nitrogen; calcium fluoride, however, reduces the temperature at which absorption of nitrogen can take place and also keeps down the temperature of reaction by at least 100°C . The heat produced is not sufficient, even with carbide alone, to carry the reaction through a mass of cold material, when started at one point. Experiments at temperatures between 920° and 1100°C . show that addition of calcium fluoride does not appreciably affect the small proportion of cyanide formed during the production of cyanamide. The reaction, $\text{R}_2\text{N}_2\text{C} + \text{C} \rightleftharpoons 2 \text{RNC}$, tends towards the right, if R be potassium or sodium, and, the higher the temperature, the more cyanide is formed, but if R_2 stand for 1 atom of calcium, the reaction tends towards the left; thus, less than 4 per cent. of the used nitrogen is converted into cyanide by melting 0.69 gm. of calcium cyanamide with 12.5 grms. of calcium chloride, but 0.46 gm., melted with 6.0 grms. of sodium chloride, causes 69.9 per cent. of the nitrogen to be so transformed.

—F. SODN.

Radium, barium, strontium, and calcium bromides; Volatility of — A. Stock and H. Heynemann. Ber., 1909, 42, 4088-4093.

THE relative volatility of the bromides of calcium, strontium, and barium was estimated by heating the salts in a narrow quartz tube in a small electric furnace in the vacuum of a mercury pump, and noting the temperature at which a deposit of sublimed salt began to appear in the cool portion of the tube projecting from the furnace.

These temperatures are respectively for calcium bromide, 720° C.; strontium bromide, 770° C.; barium bromide, 820° C. No pure radium bromide being available, the corresponding estimation for that salt could not be made; but fractional sublimations of three samples of radio-active barium bromide ($\text{I}_{100}^{\text{Ba}}$, $\text{I}_{100}^{\text{Ba}}$, $\text{I}_{100}^{\text{Ba}}$, of radium salt) showed that the sublimed portion always contained a lower proportion of radium than the residue, the difference between the two being less as the sublimed portion formed a greater proportion of the whole. Possibly fractional sublimation may in certain circumstances be a convenient method for the concentration of radium compounds. —J. T. D.

Iodine; Oxidation of —, by means of ozone. F. Fichter and F. Rohner, Ber., 1909, 42, 4093-4100.

THE authors have re-investigated the product described by Ogier (Comptes rend., 1877, 85, 597, and 1878, 86, 722) and formulated by him as I_2O_5 . By using a solution of iodine in chloroform instead of iodine powder or vapour, and oxygen much richer in ozone than was obtainable in 1877, they have prepared larger quantities of the substance, and have shown that its composition agrees most nearly with the formula I_4O_9 . They regard it as the iodate of trivalent iodine, $\text{I}(\text{O}_3)_3$. Its most striking character is the avidity with which it absorbs moisture from the atmosphere, the yellow powder sinking down into a brown liquid, which consists of iodine and iodic acid— $5\text{I}_4\text{O}_9 + 9\text{H}_2\text{O} = 18\text{HIO}_3 + \text{I}_2$. —J. T. D.

Arsenic; Phosphorescence and oxidation of —. L. Bloch, Comptes rend., 1909, 149, 775-777.

THE author finds that when arsenic is oxidised by either air or pure oxygen, arsenic anhydride is always produced whether the phenomenon is accompanied by phosphorescence or by flame. The lower the temperature at which oxidation takes place, the greater is the proportion of arsenic anhydride obtained. In the most favourable experiment 1/30th part of the arsenic was converted into the anhydride. The latter is formed directly in this reaction and is not due to further oxidation of arsenious anhydride, as this was not oxidised when heated in a current of air at 250°-450° C. —J. C. C.

Alumina; Manufacture of —. G. McCulloch, East St. Louis, Ill., Assignor to Aluminum Co. of America, Niagara Falls, N.Y. U.S. Pat. 938,269, Oct. 26, 1909.

IN the preparation of alumina from bauxite, after precipitating alumina from sodium aluminate solution by means of carbon dioxide, caustic alkali is added to the precipitate with the object of dissolving the silica precipitated with the alumina. The liquor containing the re-dissolved silica and alumina is withdrawn, and used for the treatment of further quantities of bauxite. —O. R.

Soda; Recovery of — in the manufacture of alumina. H. C. Peffer, East St. Louis, Ill., Assignor to Aluminum Co. of America, Pittsburg, Pa. U.S. Pat. 938,270, Oct. 26, 1909.

THE residual red mud, left in the manufacture of alumina from bauxite by the alkaline process, is heated with lime, or digested with lime and water under pressure, thereby rendering the soda soluble, after which the solution is filtered and the soda recovered. —O. R.

Alumina; Removal of silica in the manufacture of —. H. C. Peffer, East St. Louis, Ill., Assignor to Aluminum Co. of America, Pittsburg, Pa. U.S. Pat. 938,432, Oct. 26, 1909.

IN the process of preparing alumina from bauxite, in which the latter is digested with lime and sodium carbonate,

the sodium aluminate liquor formed is allowed to remain in contact with the residual red mud for about 6 hours to cause the precipitation of the silica. —O. R.

Slags and burnt pyrites containing barium and iron; Process for treating —. R. Alberti, Ger. Pat. 215,020, July 3, 1908.

THE powdered material is mixed with a quantity of hydrochloric acid sufficient to convert the metals into chlorides, and is then treated with superheated steam at a temperature of about 300° C., but not exceeding this. The sulphides present are decomposed and free sulphur distils over, together with hydrochloric acid resulting from the decomposition of iron and manganous chlorides; the reaction is complete when the issuing steam no longer has an acid reaction. By extracting the residue with water, a solution is obtained containing barium, zinc, and copper chlorides, and free from iron. —A. S.

Perborate preparations; Manufacture of solid, durable —. Chem. Werke vorm. Dr. H. Byk, Charlottenburg, Germany. Eng. Pat. 7495, March 29, 1909. Under Int. Conv., April 14, 1908.

VIII.—GLASS, POTTERY, AND ENAMELS.

Mosaic glass; Production of —. O. Parkert, Sprechaal, 1909, 42, 671.

MOSAIC glass is made by printing the mosaic design on to well-annealed flint glass by means of a transfer. The transfer is made by pouring a mixture of 20 parts of a solution of size, 10 parts of glucose, and 5 parts of glycerin, into plaster moulds cut to the required pattern, and soaked with paraffin. When the mixture has set, it is carefully removed and placed on a wooden plate dusted with resin. In the process of printing from the transfer, a thick syrup of gelatin solution and finely-powdered borax is used as medium, applied to the transfer by a fine hair-pencil. Ground lead-glass is now blown on to the ware, and whatever does not adhere is shaken off. The ware is then burnt again in a muffle-kiln. The firing must be carefully conducted, as many colours develop at a comparatively low temperature. The kiln is fitted with a press-roll to smooth out inequalities of the mosaic surfaces. Mosaic decoration on hollow glass ware is attended with greater difficulty. Gum-transfers are used, and a protecting composition is applied where the design is not wanted. —H. H. S.

PATENTS.

Glass annealing furnaces or ovens and the like. L. Rembaux, Maubrier s/Sambre, Belgium. Eng. Pat. 25,797, Nov. 30, 1908.

A CONTINUOUS annealing plant is described consisting of a series of ovens through which the charge of glass, supported on a suitable table or truck, is consecutively passed, each oven having a lower temperature than that from which it receives the glass. The ovens are separated by movable partitions, and the truck or table is heated in the first oven, and then moved along rails into the second oven, where it receives the sheet of cast glass. The first oven is heated by gas, and the waste gases are drawn from it down through refractory chequer-work below part of the floor of the second oven, passing up through openings in the floor, and then down through a second block of chequer-work, and on to the next oven. The

ovens are provided with flues for drawing off the heating gases in order to regulate the temperature as required. Hoists with the necessary accessories are provided at each end of the series of ovens, so that a tile which has passed through all the ovens can be returned to the preliminary heating oven. A series of annealing ovens may be arranged on each side of the casting house.—W. C. H.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

Colloids in clays. Rohland. *Sprechsaal*, 1909, 42, 655—657.

ACCORDING to the author the characteristic properties of clays, especially their plastic properties, are due to colloidal ingredients, especially to colloidal hydroxides of silicon, aluminium and iron, formed during the weathering of the granitic rocks from which clays are originally formed. Colloidal organic substances are also present and play a part in rendering the clay plastic. Pure kaolin only shows plastic properties to a small degree and in some cases not at all, as the active colloids have been removed in the process of sedimentation. Aluminium silicate itself is quite devoid of plastic properties, and very plastic clays, rich in zinc, are known which contain only 1 per cent. of aluminium silicate, but in contact with water, form colloidal zinc and silicon hydroxides. The author finds that strongly plastic clays adsorb colloids, dyestuffs of complicated composition, CO_3 -ions from carbonates, HCO_3 -ions from bicarbonates, B_4O_7 -ions from borates, and PO_4 -ions partially from phosphates. When digested with a mixture of water and an aromatic hydrocarbon, a certain quantity of the water is absorbed and the clay becomes absolutely impervious to the hydrocarbon, though water diffuses through it. Fuller's earth apparently also absorbs alcohol, acetone and other substances containing oxygen.—E. F.

Colloids in clays; Quantitative determination of —. K. Endell. *Z. Chem. Ind. Kolloide*, 1909, 5, 244—245.

THE dry, powdered clay is boiled with Canada-balsam, and after cooling, a section is prepared by polishing. This is then dyed for 12 hours in a cold, concentrated solution of Magenta and washed. The colloidal portions of the specimen become dyed and show a bright red colour, the other portion being yellow. A microphotograph of 280 diameters magnification is then prepared. The proportion of colloidal material can be estimated by cutting out the dark (colloidal) portions of the photograph and weighing, the whole photograph being also weighed.—E. F.

Cements; Solution and decomposition of —. Maynard. *Tonind.-Zeit.*, 1909, 33, 1462—1463.

THE author analysed specimens of Portland cement that had been exposed to the action of fresh water and of sea water for periods ranging from one day to 2½ years. He concludes that: (1), Even distilled water attacks cement in the course of time, lime entering into solution and diffusing to the surface of the cement; (2), cement combines with a considerable quantity of water in the course of time, and consequently; (3), the absolute volume of its constituents increases. (4), Silica does not appear to enter into solution within the range of time occupied by the experiments; (5), the amount of free lime increases for the space of one year, after which it decreases again; (6), sodium chloride is especially active in causing the decomposition of cement, calcium silicates being dissolved with the formation of a compound, the composition of which is still undetermined.—O. R.

Hydraulic binding materials; Behaviour of — in sea-water. M. Gary and C. Schneider. *Mitt. Königl. Materialprüfungsamt*, 1909, 27, 239—317.

A COMPREHENSIVE and detailed account of experiments still in progress on the behaviour in fresh water and sea

water of cement-mortars and cement-concretes prepared with and without addition of trass. The experimental results so far obtained are given in a large number of tables and curve-diagrams.—A. S.

Iron Portland cement [slag cement] in comparison with Portland cement; Examination of —. M. Gary and H. Burchartz. *Mitt. Königl. Materialprüfungsamt*, 1909, 27, 338—372.

AN account is given of a comprehensive series of comparative experiments with cement mortars prepared with iron Portland cement and Portland cement respectively, by a commission appointed in 1902 by the Prussian Minister of Public Works. After consideration of the results obtained, the commission reported on June 5, 1908, that iron Portland cement and Portland cement may be considered of equal value. If in air-hardening tests under standard conditions, iron Portland cement gives satisfactory results, there is no objection to be raised against its use in public buildings. Similar considerations are said to apply to the addition of suitable slags to ordinary Portland cement.—A. S.

Influence of calcium carbonate on waterglass solution. Kallauner. *See VII.*

PATENTS.

[Brick] kilns. E. Boyone, Novi Ligure, Italy. Eng. Pat. 27,000, Dec. 12, 1908.

IN kilns of the Hoffmann type, in order to prevent the unequal burning of the bricks, some of the rows of bricks in the lower tiers are arranged on a slide which passes transversely across the sole of the kiln. The bricks stacked on the slide are arranged so as to be independent of the others, and are free to be moved without disturbing the remainder. When it is judged that the lower rows are sufficiently burned, the slide is moved transversely by means of a crank and rod, fastened to it and which passes up through the wall of the kiln. In this way the passage of the gas through the lower horizontal rows of bricks is obstructed and it rises upwards and heats the upper rows only.—W. H. C.

Paving brick; Vitrified —. K. Langenbeck, Boston, Mass. U.S. Pat. 937,822, Oct. 26, 1909.

THE brick consists essentially of sifted coal ashes, "possessing the capability of felting," and of a bond of clay, which is more fusible than the ashes, the proportion of the clay used being insufficient to prevent the "felting" of the ashes.—O. R.

Wood; Process of preserving —, and a composition therefor. F. Hasselmann, Munich-Nymphenburg, Germany. Eng. Pat. 12,587, May 27, 1909. Under Int. Conv., May 27, 1908.

WOOD is treated with a solution, which is heated to a temperature of approximately 100° C., and is continuously agitated. The wood is left in the solution while it cools, and is then dried. The solution contains approximately 1.5 per cent. of ferric chloride, 2 per cent. of ammonia-alum, or schoenite, and 1.5 to 2 per cent. of magnesium chloride.—W. C. H.

Wood; Art of colouring and graining —. W. A. Hall, New York, Assignor to American Mahogany Co. U.S. Pats. 939,014, 939,015, and 939,016, Nov. 2, 1909.

(1), A VARIEGATED coloration is produced in wood, by treating it with a solution containing ingredients of different capillary activities or different penetrating qualities, in a closed vessel, which can either be exhausted, or in which the pressure can be raised. (2), Wood containing tannin is heated in a closed receptacle, from which the air is afterwards exhausted; ammoniacal gas is forced into the wood by pressure, and permeating it throughout, acts chemically on the tannin to colour the wood. The gas is removed from the wood by a second vacuum treatment. (3), Wood is artificially grained and coloured by indenting the surface to imitate grain figures, withdrawing the air from the wood by means of a vacuum, and then

forcing a colouring solution into and throughout the wood by pressure, and diffusing the colouring material by a boiling or steaming process, so that the colouring matter is largely lodged as a pigment deposit in the softer and indented portions, and also diffused throughout the denser portions of the wood. In this way a common wood is made to resemble a rare wood in shade and appearance. (See also U.S. Pats. 933,435—933,437 of 1909; this J., 1909, 1037.)—W. C. H.

Asphalt; Method of rejuvenating — J. A. W. Pine, New York. U.S. Pat. 938,698, Nov. 2, 1909.

THE method is applicable to asphalt which has partly or entirely lost its binding power through chemical action, or through causes other than injury due to wear or abrasion, and consists in heating the material to a temperature of between 300° and 400° F., in such a way that the heat penetrates uniformly throughout the mass, which is mechanically agitated during the heating process.

—W. C. H.

Calcium hydroxide mixtures which can be cast; Process for the preparation of — M. Schumacher. Ger. Pat. 215,161, Nov. 17, 1906.

SLAKED lime is mixed to a stiff paste with water and this is incorporated with a small quantity (2 per cent.) of a carbohydrate, such as gum, dextrin, or sugar, and 0.25 to 1 per cent. of alkali. The mixture becomes more fluid and can be cast in plaster moulds. Filling materials, such as sand, cellulose, peat, &c., may be added.—A. S.

Cement from blast furnace slag; Manufacture of — G. F. Metzger, Manchester. Eng. Pat. 15,164, June 29, 1909.

CEMENT is manufactured from hot blast-furnace slag by the application of water only, which is correctly proportioned to the temperature, flow, and quantity of the slag to cause the necessary reaction and ensure efficient granulation. The process may be carried out in any suitable machine or apparatus, the necessary ingredients being added, or the chemical proportions of the slag being varied inside the blast-furnace, to produce any particular quality of cement required.—W. C. H.

Cement and other products; Process of making — S. Peacock, Chicago, Ill., Assignor to American Cyanamid Co., New York. U.S. Pat. 939,078, Nov. 2, 1909.

By this process free phosphorus pentoxide and Portland cement are made in a single operation from phosphate rock. Silica is added to the rock, if necessary, so that the ratio of the total silica to the total alumina and ferric oxide together may be greater than 2, and less than 4, and enough lime, or its equivalent of calcium carbonate, is added to the rock mixture to combine with all the acidic oxides present. The quantities stated are 100 lb. of phosphate rock, about 8.3 lb. of silica, and 51.6 lb. of calcium carbonate. The mixture is suitably prepared and treated to form Portland cement and drive off phosphorus pentoxide which is then recovered.—W. C. H.

X.—METALS AND METALLURGY.

Coal and iron industries; Development of the — Greville Jones. Cleveland Institute of Engineers, Presidential Address, Nov., 1909.

IN the coal industry extensive developments have been carried out in South Yorkshire within easy distance of the iron and steel works in the Frodingham district, and the result will be, in the author's opinion, that it will be possible to produce in the Lincolnshire district, the cheapest pig-iron in the world, since besides coal, cheap self-fluxing ores are available. At the Barfoed Colliery in South Wales there is an installation of 100 Koppers by-product coke-ovens, and a washer capable of dealing with 120 tons of coal in 12 hours. By the washing process, small coal containing 6 per cent. of ash and 1.1 per cent. of sulphur is obtained from a mixture of "smalls" and dirt containing 20 per cent. of ash and 1.5 per cent. of sulphur. The gas from the coke-ovens is used for power purposes on the spot and is also conveyed to other collieries, some of which are 1½ miles distant. With respect to coke-ovens, in the United Kingdom there are in operation 2505 Coppée ovens without by-product plants and 5111 by-product ovens classified as follows: Simon-Carvès, 1201; Semet-Solvay, 1150; Otto, 1052; Koppers, 638; Simplex, 334; Coppée, 314; Huessener, 260; Collins, 50; Bauer, 12; others, 100.

Iron ore.—Large deposits of ore have, it is said, been found in Kent and Sussex; near Dover, the seam has been proved to a depth of 17 feet, and will, it is estimated, produce 107,000 tons per acre. The calcined ore contains 45 per cent. of iron; ore from the middle of the seam contains 49 per cent. The pisolitic iron ore from the deposit opened up in Carnarvonshire contains about 45 per cent. of iron, 15 of silica, 5.75 of lime, and 1—1.73 of phosphorus. In the author's opinion it would be suitable for use in place of puddler's "tap" in the manufacture of basic pig-iron for the basic steel process.

Iron manufacture.—There is only one dry-air plant (see Gayley, this J., 1904, 1148) at present in operation in the United Kingdom, viz., at Cardiff. The results obtained with hematite ore are shown in the following table, together with the average results obtained at Blaenavon, using ordinary air.

	Output.	Coke consumption.
Cardiff—	tons.	lb.
Average for 50 weeks with ordinary air	2001	2278
Average for 5 weeks with dry blast, operated for increased output	2530	1972
Average for 4 weeks with dry blast, operated for economy ..	2286	1857
Blaenavon—		
Average for 4 years with ordinary air	1238	1981

Dry-air plants are about to be installed at single works in Great Britain, Canada, and Germany, and at seven different works in the United States.

Blast-furnace gas.—At several places plants are in operation for the utilisation of blast-furnace gas for power purposes (see also this J., 1909, 603).

Steel manufacture.—Owing to the tendency of the available iron ores to increase in phosphorus-content, the acid Bessemer process will probably gradually be dispensed with. In the manufacture of basic Bessemer steel, the chief improvements have been the introduction of the Flohr process (see Goerens, this J., 1908, 571) and the Massenez process (see Richards, this J., 1907, 694). The greatest improvements in recent years have been made in the basic open-hearth process. The chief of these are:—(1), the use of molten iron; (2), the adoption of the mixer, whereby a regular supply of metal of uniform quality is insured; (3), the mechanical charging of scrap and ore; (4), furnaces of larger capacity, whereby a greater surface

of the metal is exposed to oxidation, and owing to the larger size of the regenerators, the fuel consumption is reduced. At several works the gas-producers used in connection with the open-hearth furnaces are provided with plants for the recovery of the ammonia, a yield of 95–105 lb. of ammonium sulphate per ton of fuel consumed being obtained; even with a yield of only 90 lb. of ammonium sulphate, the saving would amount to ls. 6d. per ton of steel made. In America, the use of the Blair water-cooled blocks in open-hearth furnaces (see Fr. Pat. 382,135; this J., 1908, 232) has effected considerable economy. *Talbot furnaces* (see this J., 1900, 539). Ten of these furnaces are now in operation in the United Kingdom, and there are 13 in course of construction.

Electric furnaces. (See this J., 1907, 327, 767; 1908, 691, 757, 817; 1909, 208, 1046). The number of electric iron and steel furnaces at present in operation or in course of construction, in different countries is as follows:—Germany, 20; Italy, 12; France, 12; U.S.A., 9; England, 6; Switzerland, 6; Austria, 5; Sweden, 5; Luxemburg, 4; Belgium, 2; Bohemia, 1; Brazil, 1; Spain, 1. Of the English furnaces, three are of the Kjellin type, two of the Frick type, and one of the Héroult type. The results of tests made by Guillet as to the uniformity of steel made in the Héroult electric furnace, are shown in the following table:—

	Soft steel.				Hard steel.					
	Large ingot.			Small ingot.	Large ingot.			Small ingot.		
	Top.	Middle.	Bottom.	Middle.	Top.	Middle.	Bottom.	Top.	Middle.	Bottom.
Carbon	0.084	0.069	0.068	0.070	1.015	1.016	1.022	1.018	1.013	0.22
Silicon	0.036	0.034	0.038	0.030	0.103	0.101	0.103	0.098	0.100	0.101

(See also Harbord, this J., 1909, 867.)—A. S.

Norwegian iron industry; Development of the —.
Chem.-Zeit., 1909, 33, 1199.

A ROYAL Commission has been engaged in Norway with the question of the development of the iron industry with the aid of electric power. The present production of iron ore in Norway is over 100,000 tons per annum, and it is estimated that it will soon reach 1,000,000 tons. The most important deposits of ore occur in North Norway, two types being recognised, viz., the Dunderlands and South Varanger types. At Dunderlands the conditions are unfavourable, but at South Varanger, there is a cheap supply of ore which can be concentrated magnetically with a small expenditure of power; it is anticipated that the production here will soon reach 600,000 tons per annum. In North Norway it is estimated that there are about 350 million tons of crude ore, of which 200 million tons consist of magnetite. In the Trondhjem district the ores contain sulphur, but this will not stand in the way of their use in electrical smelting processes; in this district there are about 20 million tons of ore with a content of 55 per cent. of iron. In Western Norway there are large deposits of titaniferous iron ore suitable for the manufacture of ferro-titanium; it is estimated that about 5 million tons are available. There are also several deposits of iron ore, amounting in all to about 5 million tons, in the southern and eastern parts of Norway.—A. S.

Malleable cast iron. R. Namias. Seventh Int. Congr. Appl. Chem., London, 1909. Engineering, 1909, 88, 669.

In the author's opinion sufficient attention is not paid to the chemical action taking place in the conversion of white cast iron into malleable iron. The composition of the

white cast iron used is of great importance; it should be comparatively low in silicon and manganese, as although up to 0.5 per cent. of silicon is beneficial, in that it facilitates the separation of graphite, an excess renders the product less malleable. As oxidising material, slightly better results were obtained with a mixture of ferric oxide and lime than with ferric oxide and quartz sand. In an Italian works the best results have been obtained with a mixture of small iron refuse and forge scale. The malleable iron prepared with this mixture from a silicious cast iron had the following composition at the surface and at a depth of 1–2 cm. respectively:—sulphur, 0.133, 0.148; phosphorus, 0.100, 0.103; manganese, 0.62, 0.61; silicon, 0.062, 1.59; (1) carbon, 0.28; (2), combined carbon, 0.35; graphitic carbon, 1.36 per cent. The author has made experiments with an oxidising mixture composed of carbon dioxide in presence of ferric oxide and a basic substance; the best results were obtained with a mixture of 1000 parts of ferric oxide, 50 of graphite and 150 of magnesia, carbon dioxide being evolved gradually and continuously. The carbon monoxide produced by the action of the carbon dioxide on the carbon of the cast iron, was re-oxidised to carbon dioxide by the ferric oxide. This mixture yielded results similar to those obtained with the mixture of iron refuse and forge-scale, and was cheaper and easier to prepare.—A. S.

Etching [iron and steel] with cuprammonium chloride.
M. Widemann. Stahl u. Eisen, 1909, 29, 1823–1824.

THE author has repeatedly tried to use cuprammonium chloride for etching steels for microscopic examination, but has found that the precipitated copper has greatly interfered with the method. In order to overcome this difficulty, the polished specimen is moved about rapidly in a large dish containing the etching solution, the polished surface being uppermost. As soon as sufficient action has taken place, the piece of metal is rinsed in running water, and while still wet, immersed in a 30 per cent. solution of potassium cyanide heated to 50° C. After 1–10 minutes the whole of the copper has dissolved; the specimen is now washed with water and dried in the usual manner. This method has been used with very great success on a great variety of steels.—A. H. C.

Titanic acid in ilmenite; Determination of —. E. Röer.
Chem.-Zeit., 1909, 33, 1225.

THE finely powdered ilmenite (0.5 gm.) is fused with sodium carbonate (10 grms.) first of all over a Bunsen, then over a blow-pipe flame for half an hour, the melt poured into a platinum dish to cool, then transferred, together with the crucible, to a beaker, covered with 50 c.c. of water and allowed to stand for 12 hours. The insoluble matter, consisting of sodium titanate, iron oxide, lime, and magnesia, is filtered off, washed with cold water and, by piercing the filter, introduced into a litre flask. The beaker and crucible are rinsed with a mixture of hot dilute hydrochloric and sulphuric acids, which is poured over the filter, and the latter then washed with boiling water. Should undissolved sodium titanate or iron oxide remain in the flask, the contents of the latter are boiled with a little dilute sulphuric acid until the liquid becomes clear or only a white precipitate remains. On cooling, the solution is made just alkaline with caustic soda, then faintly

acid with sulphuric acid, and 100 c.c. of saturated sulphurous acid together with boiling water added to make the volume 700 c.c. The whole is now boiled for an hour, and after addition of 20 c.c. of sulphurous acid, allowed to stand until the precipitated titanous acid has settled. It is collected on a thick filter, washed with boiling water until free from chlorine, incinerated and ignited as usual. In this process it is essential that sufficient sulphurous acid be added to completely reduce the iron present.—J. L. H.

Tungsten ores; Occurrence and utilisation of —. Bulletin Imp. Inst., 1909, 7, 285—295.

THE following table gives, as far as possible, the production of tungsten ores for the period 1905—1907:—

	1905.		1906.		1907.

* Tin and wolfram ores.

The price obtainable for tungsten ores is affected in a very disproportionate degree by the percentage of tungstic oxide, WO_3 , present and also by their freedom from certain impurities. It is stated that the phosphorus and sulphur content should not greatly exceed 0.25 and 0.01 per cent. respectively. In Colorado in 1907, the price per unit of tungstic oxide in ores containing from 3 up to 60 per cent. of the oxide ranged from 13s. 5d. to £1 19s. 7d.

Tungsten is a bright grey metal with a hardness between 5.4 and 6, and having a sp. gr. of 19.13. Its melting point, according to a recent determination, is 3080° C. The chief application of tungsten is in the manufacture of steel, the tensile strength and elastic limit of which are raised, within certain limits, in proportion to the amount of tungsten present. The elongation, reduction of area, and resistance to shock diminish proportionately, whilst the hardness increases somewhat rapidly with the percentage of tungsten. Tungsten steels are largely used for the manufacture of high-speed tool-steels as they retain their temper even when worked red hot. A typical steel of this type contains 8.5 per cent. of tungsten, 4 of chromium, and 1.25 of carbon. An important use for tungsten is in the manufacture of filaments for electric glow lamps, which are claimed to have an efficiency of 1 to 1.2 watts per candle-power. The salts of tungsten are used, to a limited extent, in rendering wood and textile fabrics fireproof, as a mordant for silk and wool, and for colouring pottery, etc.—F. R.

Cuprous oxide in copper and its alloys; Determination of —. R. H. Greaves. Chem. News, 1909, 100, 233—235.

THE author has examined the method devised by Coffetti (this J., 1909, 313), which is based on the fact that cuprous

oxide is soluble in ammonia in absence of oxygen, whereas copper is insoluble. In order to shorten the time required, the apparatus was modified so that a greater surface of the copper was in contact with the ammonia solution. For mixtures of pure copper with cuprous oxide, the method was found to give excellent results, but when arsenic is present, the results are too high. Useful results can, however be obtained in the latter case by determining the arsenic dissolved, and making a correction on the basis that it dissolves as copper arsenate. Antimony has an effect similar to that of arsenic. When iron is present in metallic copper containing oxygen, it exists wholly or partly as oxide, and hence the total oxygen and oxygen present as cuprous oxide do not correspond. Serious errors

due to the presence of antimony and iron are not likely to occur with commercial coppers. The method appears to yield useful results with brass and bronze, but in the case of the latter it should be borne in mind that the injurious constituent is mainly stannic oxide.—A. S.

Zinc; Determination of — and the analysis of zinc ores. K. Voigt. Z. angew. Chem., 1909, 22, 2280—2285.

If ammonium phosphate be added to an ammoniacal solution of a zinc salt, and the solution be heated until it gives the amphoteric reaction (i.e., turns red litmus blue, and blue litmus red), the zinc is completely precipitated as the highly crystalline zinc ammonium phosphate. This on filtration, washing with water, and drying at 100° C., and igniting separately from the filter-paper, yields zinc pyrophosphate in which form it may be weighed; for calculating the zinc a factor of 0.4291 is used. The author uses this method for the estimation of zinc in zinc blende. After solution in *aqua regia*, the silica, alumina, iron and manganese are separated and estimated in the usual way. The lime, however, is separated by the use of ammonium carbonate instead of as oxalate, and the magnesium ammonium phosphate is precipitated by a 10 per cent. solution of ammonium phosphate free from sodium salts, the zinc remaining in solution. The zinc ammonium phosphate is now completely precipitated by heating the solution on a water bath, and finally on an asbestos plate until the above amphoteric reaction is obtained.—A. H. C.

Zinc blende; Interaction of carbon and silicon with — at high temperatures. W. Fraenkel. Metallurgie, 1909, 6, 682—688.

REFERENCE is made to previous work on the reduction of zinc blende, and to the possibility of the formation of

volatile sulpho-carbonyl compounds analogous to the metal-carbonyl compounds. Proceeding on the assumption of Percy and others, of the formation of zinc and carbon bisulphide from zinc blende and carbon, a mixture of very pure zinc-blende and sugar charcoal was heated in a quartz boat in a quartz tube in a Heraeus furnace. The temperature was determined by a thermo-junction close to the boat, and a stream of purified nitrogen was passed through the tube, carrying any volatile products against a water-cooled quartz tube at the other end. It was found that a mixture of 90 per cent. of zinc blende and 10 per cent. of carbon could be completely volatilised at a temperature of about 1350° C. without the formation of even traces of carbon bisulphide. A sublimate was formed, however, on the water-cooled tube, of which the analysis closely agreed with the composition, $ZnSSi$. It was a hard brittle substance, with a lustre like that of silicon, and a polished and etched specimen appeared homogeneous under the microscope. It evolved sulphuretted hydrogen when treated with acids, and hydrogen when treated with caustic alkalis. Experiments with a carbon boat showed that the silicon was derived from the quartz tube. A mixture of zinc blende and silicon gave the same volatile product. The author confirms the observation of Lepiarczyk (this J., 1909, 838), that a volatile product of zinc sulphide and carbon is formed in the zinc muffle, and shows that this vapour is able to reduce silica to silicon, producing a volatile substance which appears to be a molecular compound of zinc sulphide and silicon. In the technical production of zinc, owing to the presence of a large amount of silica in the zinc muffle, it is considered that there is a considerable loss of zinc due to the formation of this volatile product.—A. H. C.

Zinc alloys. B. E. Curry. J. Physical Chem., 1909, 13, 589—605.

THE melting-point curve of antimony-zinc alloys was re-determined by means of heating curves in place of cooling curves, in order to avoid errors caused by supercooling. The equilibrium diagram consists of six phases: pure antimony, pure zinc, the compound, $ZnSb$, and three series of solid solutions, α , β , γ . The α - and β -phases are not stable below 437° C. and 405° C. respectively, and the γ -phase is only stable below the solidifying point. Alloys with more than 45 per cent. of zinc are not homogeneous under any condition, and below 405° C. they consist entirely of γ -crystals and zinc. The freezing-point curve of zinc-tin alloys shows the absence of compounds. The two phases in the equilibrium diagram are pure zinc and a solution of zinc in tin. The alloys show a gradation in softness from pure zinc to pure tin, pure zinc being harder and more brittle than any of its alloys with tin. The freezing-point curve for zinc-cadmium alloys is similar to that of the zinc-tin series, the two phases being, in this case, the solid solutions of zinc in cadmium and of cadmium in zinc. The miscibility of zinc and lead and of zinc and bismuth is very slight; at the freezing point, mixtures of lead and zinc separate into two layers consisting practically of the pure metals, and in the latter case the phases separating are pure zinc and a solid solution of zinc in bismuth.—F. R.

Melting point determinations. W. P. White. Amer. J. Science, 1909, 28, 453—473.

THE author discusses the question of the determination of melting points (especially of metals and silicates) from temperature-time curves. As the result of numerous experiments on a number of substances, organic and inorganic, melting at temperatures between 0° and 1400° C., the methods employed in the geophysical laboratory of the Carnegie Institution, Washington, have been so improved, that the agreement of determinations of the melting points of silicates has increased about five-fold. The chief conclusions drawn from the investigation are as follows:—Melting and freezing point (temperature-time) curves of pure substances should consist of two vertical branches joined by a horizontal line corresponding to the melting point. Curves plotted from experimental data are, however, nearly always oblique—that is, they show an

interval within which the temperature continuously rises or falls, instead of a constant temperature. The chief cause of this obliquity is the presence of impurities in the substance under examination. The true melting point corresponds to the upper end of the oblique melting interval. In the case of some very viscous substances, mostly boron and silicon compounds, melting hysteresis ("time-lag") may be a serious cause of obliquity of the curve, e.g., the melting may take place only gradually even at temperatures 100° or more above the true melting point. This phenomenon may be recognised by the variability of the melting temperature with the rate of heating. In making determinations of the melting point of impure substances by the thermal method, more attention should be paid to the supply of heat to the charge; if this varies, the curve is distorted. Commonly the temperature of the furnace is made to rise or fall continuously and uniformly, but as the charge during melting or freezing remains at a practically constant temperature, the rate of supply of heat to the charge under the conditions stated will vary considerably. The freezing point is easier to observe than the melting point, but is inadmissible in the case of substances which show marked undercooling. The melting point curve is liable, where stirring is not practised, to obliquities caused by uneven temperature distribution, due to the difference of temperature between the inside and outside of the charge; also by irregularities in the flow of heat and conduction of heat by the thermo-element—these are less with narrow charges and small thermo-elements, but the error due to the latter cause may be several degrees with enclosed thermo-elements. Errors may also be introduced by electrical conductivity of the melt, when bare thermo-elements are used, contamination of the thermo-elements, and differentiation (melting of portions of charge of varying purity at different temperatures) and diathermaney of the charge. Melting points above 800° C. have been determined with results agreeing to within 0.05°, but in most cases at high temperatures, differences of from 0.5 to 1.5° C. are found, the cause of which has still to be determined.—A. S.

Melting point methods at high temperatures. W. P. White. Amer. J. Science, 1909, 28, 474—489.

FOR the determination of melting points at temperatures up to 1600° C., platinum resistance furnaces of simple construction (see Day and Allen, Phys. Rev., 1904, 19, 177) can be used with good results. Where uniformity of temperature throughout the working chamber is important, this is made higher and narrower, and fitted with four horizontal partitions to ward off the cooling effect of the ends, and a porcelain tube is disposed in the centre of the chamber to receive the crucible containing the substance. It is best to work with small quantities (2.5 grms.) of the substance, and it is advisable to use a second thermo-element to give directly the temperature in the neighbourhood of the charge, besides that giving the temperature of the furnace, since the measurement and regulation of the heat supply from the furnace to the charge is of great importance. Methods of treating and insulating thermo-elements and of avoiding the effects of contamination are described (see also Phys. Zeits., 1907, 8, 332). The melting points of very viscous substances, showing hysteresis or time-lag, can be determined accurately by slow heating, with occasional examination outside the furnace. Latent heats of fusion can be determined approximately from melting-curves by measuring the furnace temperature, but if the error is not to exceed 10 per cent. (about 10 calories in many silicates), special apparatus and methods of procedure are necessary. The smaller latent heats of transformation can usually be determined, within one or two calories, with no other apparatus than the two thermo-elements. For the determination of faint or sluggish thermal effects, rapid rates of heating and great precision in the regulation of the furnace and measurement of temperature are required. In order to accurately determine eutectic points by the thermal method, a means of detecting the presence of small residues of the component in excess is required (see Amer. J. Science, 1909, 27, 11).

—A. S.

Corrosion of metals; Paint and varnish coatings as accelerators in the —. W. H. Walker and W. K. Lewis. J. Ind. Eng. Chem., 1909, 1, 754—758.

It has been found that, in tin cans which have been lacquered inside with copal linseed oil varnish boiled at 140°—150° C., the corrosion has been much more rapid under the action of strongly acid fruits than in the case of untreated cans. This rapid corrosion takes place at the points where the lacquer has been removed in soldering, etc., and is sometimes so pronounced that a leak has resulted in a few weeks. The authors find that the explanation of this action lies in the depolarising influence of the lacquer itself, coupled with the action of the small proportion of air left in the can. The "linoxylin" coating being still unsaturated will absorb hydrogen. The protected surfaces will be thrown into the cathodic state, and the solution of the metal will thus be concentrated at the exposed points, and the corrosive process will continue there until the air has been consumed and the lacquer has become saturated. The remedy in the case of the fruit cans is to find a lacquer impervious to the solution, or, failing that, one that will not act as a hydrogen depolariser. A saturated varnish may be obtained by heating an ordinary varnish for a sufficient length of time, but the authors have not succeeded in discovering a non-porous coating. These results have also an important bearing upon the resistance of metals coated with paint, etc., to corrosive influences. Exposure of such films to the air eventually renders them completely saturated, but does not destroy their porosity, or obviate the possibility of corrosion at any exposed point caused by the depolarising action of the air through the film; and this explains the deterioration or pitting of iron or steel surfaces at places where the paint has peeled off.—C. A. M.

Mineral production of India. Board of Trade J., Nov. 18, 1909. [T.R.]

THE following table shows the production of minerals, metals, &c., in India in 1907 and 1908 (see also this J., 1909, 1132):—

		1907.		1908.	
		Quantity.	Value.	Quantity.	Value.
			£		£
Coal	tons	11,147,339	2,609,726 (a)	12,769,635	3,356,209 (a)
Gold	ozs.	557,686	2,126,756	567,780	2,177,847

Vanadium ore in Peru; Discovery of —. Board of Trade J., Nov. 18, 1909. [T.R.]

DISCOVERIES of vanadium ore have recently been made in the Cerro de Paseo mining district. The exports of vanadium sulphites from Callao were 412 metric tons in 1907 and 1,805 metric tons in 1908. Samples of ore similar to that exported from Cerro de Paseo may be seen at the Commercial Intelligence Branch of the Board of Trade, 73, Basinghall Street, E.C.

Tellurium production of United States. Mineral Resources for 1908. [T.R.]

TELLURIUM is found at Cripple Creek in combination with gold and silver. Smaller quantities occur there in the

oxidised form. The principal mineral, calaverite, contains on an average, Te, 57.7 per cent., Au, 41.16 per cent., Ag, 1.65 per cent. In 1908, 20 tons of gold were produced, giving about 28 tons of tellurium which could be easily saved; but no use is known for it and there is no market.

Action of feed water containing magnesium chloride on walls of steam boilers. Lange. See 1.

PATENTS.

Steel; [Crucibles for] Manufacture of —, and similar metallurgical operations. A. Reynolds, London. Eng. Pat. 14,933, July 14, 1908.

IN metallurgical operations in which crucibles are used, the crucibles are provided with lids of refractory material, similar to the crucible lining, and inert to the charge and impervious to the atmosphere, in order to prevent reactions between the charge and atmosphere or furnace gases. The lids are supported and counterpoised so as to rest lightly or float on the charge.—W. C. H.

Iron; Process for melting and refining—and apparatus therefor. H. Johnson, Saxilby, Lincoln. Eng. Pat. 22,948, Oct. 28, 1908.

THE pig or scrap iron is melted in a cupola furnace which is provided at the bottom with a well capable of holding a considerable quantity of molten metal. A small proportion of the required blast is delivered, with or without the addition of steam, under slight pressure, through tuyères placed at the top of the well, the remainder being forced under high pressure through the body of molten metal. The burning gases from the "blowing" of the iron assist in heating and melting the descending charge.—F. R.

Armour and deck plates; Treatment of —. S. S. Wales, Munhall, Pa., U.S.A. Eng. Pat. 8834, April 14, 1909.

THE ballistic resistance of non-face-hardened armour and deck plates of nickel-chromium steel, containing less than 1 per cent. of vanadium, is increased by (1), heating to

about 700° C. and slowly cooling; (2), re-heating to about 900° C. and quenching in water to 400° C. or lower; (3), again heating to between 450° C. and 700° C. and slowly cooling. The plate is toughened, if desired, by a further heating to 900° C., quenching, and annealing, or rendered more ductile by a repetition of the third step.—F. R.

Manganese steel; Treating [damaged] —. W. S. Potter, New York, Assignor to Manganese Steel Rail Co., Mahwah, N.J., U.S. Pat. 939,163, Nov. 2, 1909.

WHEN the outer portion of an ingot has become injured by overheating, the ingot is rapidly heated to above 1200° C. and the surface worked, without causing elongation, in order that the defective part shall be firmly welded

to the main body. If desired, the outer portion, after heating, is rapidly cooled below 1150° C. previous to working it.—F. R.

Copper; Extraction of — from raw unroasted ores and other products. G. Schneider, Freideburg, Assignor to E. Abresch, Neustadt-on-the-Hardt, Germany. U.S. Pat. 937,965, Oct. 26, 1909.

ORES containing copper in the form of sulphide are subjected to the action of chlorine by being mixed with manganese dioxide and treated with a solution of hydrochloric acid, with or without the addition of sulphuric acid.—F. R.

Pulverising, desulphurising, oxidising metallic and other ores; Apparatus for —. R. Luckenbach, Colwyn, Pa., Assignor to Borindum Extraction Co. U.S. Pat. 938,005, Oct. 26, 1909.

THE pulveriser consists of an outer shell having a feed hopper and a discharge shoot and containing a conical grinding drum controlled by springs and mounted on a rotatable shaft, the ore being ground between the drum and the containing shell. A roller situated within the grinding cone and geared to the central shaft has a tension bearing on the inner surface of the cone.—F. R.

Chloridising ores; Method of —. C. A. Diehl, Cleveland, Ohio. U.S. Pat. 938,044, Oct. 26, 1909.

SULPHIDE ores are chloridised by subjecting them to the action of a gaseous mixture consisting of about four molecular parts of hydrochloric acid to one molecular part of sulphur dioxide.—F. R.

Furnace; Open-hearth —. L. L. Knox, Ben Ayon, and M. Murray, Wilkesburg, Pa., Assignors to Keystone Furnace Construction Co., Pittsburg, Pa. U.S. Pat. 938,245, Oct. 26, 1909.

IN a regenerative open-hearth furnace the gas and air up-takes are provided at their upper ends with removable chambers which lead through water-cooled ports or tuyères into the furnace.—F. R.

Furnace; Regenerative reversing —. L. L. Knox, Ben Ayon, Pa., Assignor to Keystone Furnace Construction Co., Pittsburg, Pa. U.S. Pat. 938,246, and 938,426, Oct. 26, 1909.

IN a regenerative furnace the gas and air up-takes, which are constructed separately from the furnace, are furnished with removable branched tops forming ports through which the air and gas are led into the furnace, the ends of the ports being water-jacketed, or the upper portion of the up-takes are widened transversely and formed into longitudinally arched ports leading directly into the furnace.—F. R.

Furnaces; Roasting and like —. U. Wedge, Ardmore, Pa. U.S. Pat. 939,880, Nov. 9, 1909.

THE furnace consists of a number of superimposed annular hearths over which the ore is caused to travel successively, by means of mechanical stirrers. The heating gases have access to only a portion of the hearth area, the remainder being arranged as a muffle. Means are provided for collecting the gases produced in the muffle portion.—F. R.

Furnace; Roasting —. U. Wedge, Ardmore, Pa. U.S. Pat. 939,881 and 939,934, Nov. 9, 1909.

THE furnace consists of a fixed, vertical, cylindrical body containing a number of superimposed annular hearths, and a central hollow rotating shaft cased with refractory material and sealed at its lower end to prevent access of air. The upper end of the shaft is closed by an automatic charging device, and means are provided for maintaining sufficient ore above the feed openings to form a lute and render the shaft substantially gas-tight.—F. R.

Furnace; Roasting —. A. R. Willley, Denver, Colo., Assignor to J. Seep, Oil City, Pa. U.S. Pat. 939,936, Nov. 9, 1909.

THE furnace consists of a reverberatory chamber having a hearth inclined longitudinally, down which the ore

is caused to travel in a direction opposed to that of the heating gases. The hearth is cooled at suitable intervals by means of a series of independently cooled water jackets to prevent overheating and consequent fritting of the ore.—F. R.

Alloy. G. Hartmann, Assignor to Hartmann Aluminum Solder Co., New York. U.S. Pat. 938,422, Oct. 26, 1909.

AN alloy prepared from commercially pure metals is made by fusing 170 parts of aluminium with 23 parts of magnesium, then adding 7 parts of nickel to the molten alloy, and finally adding 800 parts of tin. The alloys are well agitated before the addition of the next metal, which is always added in the molten state. The final alloy is cast in heated iron moulds and slowly cooled.—F. R.

Values of metallic ore matter; Concentration by amalgamation of —. R. Luckenbach, Colwyn, Pa., Assignor to Borindum Extraction Co., Arizona. U.S. Pat. 938,676, Nov. 2, 1909.

THE apparatus consists of a cylindrical vessel provided internally with a series of shallow circular pans which are adapted to contain an amalgamating substance and caused to rotate by means of a vertical shaft passing down the centre. At the bottom of each pan, a radial slot with upturned edges extends from the centre to the circumference. An agitator frame is fixed radially over each layer of amalgamating substance, the vertical scrapers being arranged diagonally on the bars, and, compared with those on the adjacent floors, at an opposite inclination. In a similar manner, except as regards the different inclinations, a row of jet tubes is supported radially over each pan opposite the scraper-frame, and through these, liquid is delivered. The ore, mixed if necessary with the requisite amount of liquid, is charged into the apparatus through a hopper at the top.—C. A. W.

Separation process; Roasting —. H. A. Wentworth, Newton, Assignor to Huff Electrostatic Separator Co., Boston, Mass. U.S. Pat. 938,732, Nov. 2, 1909.

THE process is adapted to the separation of zinc sulphide from the sulphides of iron, copper or lead. The mixture is roasted, the intensity of the heat being such as to oxidise the sulphides of the foreign metals at least superficially, but not so great as to materially affect the zinc sulphide. Subsequently the zinc sulphide is separated from the other ingredients by a flotation process.—C. A. W.

Silver; Process of assaying for —. J. C. Hames, Goldfield, Nev. U.S. Pat. 939,413, Nov. 9, 1909.

A QUANTITY of ore pulp is mixed with camphor, iodine, potassium iodide, and a solvent, and sodium cyanide subsequently added. The silver is precipitated on metallic zinc, dissolved in nitric acid and the amount of silver nitrate determined in the usual way with suitable indicators.—F. R.

Aluminium; Solder for —. L. Goppman, Pittsburg, Pa. U.S. Pat. 939,494, Nov. 9, 1909.

THE solder consists substantially of 49.05 per cent. of tin, 3.43 of antimony, 26.06 of lead, 20.31 of zinc and 1.1 of copper.—F. R.

Armour plates or the like; Treatment of —. S. S. Wales, Munhall, Pa., U.S.A. Eng. Pat. 8835, April 14, 1909.

SEE U.S. Pat. 921,924 and 921,925 of 1909; this J., 1909, 660.—T. F. B.

Copper or copper-nickel mattes; Treatment of —. J. T. Carrick, Assignor to B. S. Pattison, Johannesburg. U.S. Pat. 939,947, Nov. 9, 1909.

(A.)—ELECTRO-CHEMISTRY.

Cadmium amalgams and the Weston normal cell. F. E. Smith. Physical Soc., Oct. 22, 1909. Electrician, Nov. 12, 1909, 199.

CADMIUM amalgams may be solid, liquid or a mixture of solid and liquid phases, the percentage composition of the phases depending on the temperature. When a completely liquid amalgam is cooled below the lower transition temperature, the centre of the resulting solid is of high cadmium concentration, and the outer skin of low cadmium concentration. Diffusion tends to produce uniformity, and, in consequence, the E.M.F. of a cell containing the amalgam is unstable for a considerable length of time. When the amalgam is slowly cooled to a temperature a little below the lower transition temperature, the difference of concentration between the inner and outer parts of the amalgam need be only small to enable the outer skin to be a two-phase system. The diffusion process will be slow and the E.M.F. may remain constant for a very long time. Amalgams which were of uniform cadmium concentration throughout were obtained by chilling completely liquid amalgams to a temperature of about -50°C .; although not initially stable, rapid diffusion processes resulted in these amalgams becoming approximately uniform throughout after a few days, and their electromotive properties were markedly different from those of slowly cooled amalgams. If, however, the temperature of such an amalgam is raised until two phases exist, subsequent cooling will not restore the uniform condition, and an unstable amalgam results. The experiments indicate that a 12.5 per cent. amalgam may be safely used at all temperatures between 12°C . and 60°C ., and a 10 per cent. amalgam at all temperatures between 0°C . and 51°C .. Experiments were made on the temperature coefficients of the anode and cathode limbs of the Weston normal cell, and show that if a difference of temperature of 1°C . exists, an error of about three parts in 10,000 is introduced.

Pig-iron; Production of —. in the electric furnace at Domnarfvet (Sweden). B. Neumann. Stahl u. Eisen, 1909, 29, 1801-1814.

From the knowledge gained by the use of several experimental furnaces for the production of pig-iron by electrical reduction, a new form of electric furnace was started in technical operation at the end of 1908. It consists of two chief parts (see fig.), the lower electric smelting region, and an upper shaft similar in shape to the usual blast-furnace by means of which the charge is supplied to the electric hearth. This smelting region comprises a circular hearth of magnesite enclosed in a sheathing of iron bands, and lined with crushed magnesite; it is 3.5 m. (11.5 ft.) in diameter, and 2.4 m. (7.9 ft.) high. It is covered over with an arch which serves for the suitable introduction of the electrodes, and from a central hole in which the shaft rises to a height of 5.2 m. (17 ft.), having a diameter of 1.525 m. (5 ft.) at the widest part. At the top of the shaft is the usual cup and cone, and means for carrying off the waste gases. The whole shaft is increased in iron, and is supported by six pillars. This form of shaft has two advantages, firstly the weight of it is taken by the pillars, and not by the arch, and secondly, it enables repairs to be more easily executed. The particular shape of the boshes, and the size of the opening in the arch enables the charge to be supplied to the hearth as a heap, the sides of which slope at an angle of 56° – 55° , leaving a circular ring of air space around it, into which the waste gases, having passed through a dust chamber, are blown. These cool the smelting area, and warm the charge descending the shaft. Through inspection holes the temperature of the arch may be watched, and the gas circulation accordingly regulated. The electrodes are double in construction and held in a steel frame with a cooling box, a wedge making a good connection with the copper plates of the cable and at the same time fixing them firmly in position. They do not go directly into the charge, but strike through the air space. The furnace only requires four men to work it, with a foreman who can also superintend another furnace, and it is emptied every six hours.

The ore contained 66.34 per cent. of magnetic oxide of iron, and 21.21 per cent. of ferric oxide, i.e. 62.96 per cent. of iron, 0.3 per cent. of manganous oxide, and 2.34 per cent. of phosphoric anhydride. The charge consisted first of 95 parts of ore, 5 of lime, and 20 of coke, then 95 of ore, 2 of lime, and 19 of coke, and finally 100 of ore, 2 of lime and 17 of coke. The coke contained 85 per cent. of carbon, and 0.55 per cent. of sulphur. An average specimen of pig-iron obtained, showed on analysis, 3.2 per cent. of carbon, 0.075 of silicon, 0.39 of manganese, 1.90 of phosphorus, and 0.015 of sulphur. The slag contained 26.54 per cent. of silica, 54.48 of lime, 0.78 of sulphur, and 0.35 of iron. Very full working details of the furnace are given in the paper.—A. H. C.

Silver mirrors; Electrolytic formation of —. R. Lohnstein. *Physik. Zeits.*, 1909, 10, 672–673. *Chem. Zentr.*, 1909, 2, 1533.

IF an E.M.F. of a few volts be applied to silver electrodes dipping into distilled water, a weak current flows, leading to the formation of a solution of silver hydroxide, while finally a glistening film of silver appears on the surface of the liquid, and small silver mirrors are produced on the walls of the containing vessel near the electrodes. Better mirrors are produced if sugar or glycerin, or a small quantity of gelatin, ammonia, potassium hydroxide, or Rochelle salt be added to the water; the best results are obtained with a 2–3 per cent. solution of sugar. The mirrors produced at the cathode are thicker than those formed at the anode, the latter being mostly very thin and transparent. Similar results are obtained when platinum or copper cathodes are used.—A. S.

PATENTS.

Steel; [Electrical] Process of producing and refining —. F. C. Perkins, Buffalo, N.Y. U.S. Pat. 937,855, Oct. 26, 1909.

THE bath of iron is fused and treated by means of an electric current, which traverses a pair of composite electrodes, containing iron and surrounded by a mixture of slag-producing materials. The ends of the electrodes are arranged at the surface of the iron bath. Slag is thus

produced on the surface of the bath, and an arc is produced between the electrodes and the slag.—B. N.

Smelting-furnace; Electric —, and art of electric smelting. E. R. Taylor, Penn Yan, N.Y. U.S. Pats. 938,351 and 938,352, Oct. 26, 1909.

THE electric furnace is formed of a suitably lined metallic shell, stack-like in form, through which horizontal electrodes extend inwardly and enclose the working chamber. An inner structure of brick or the like forms a central flue-shaped coke passage, surrounded by "coarse-ore passages" extending vertically downwards towards the plane of the electrodes, and these in turn are surrounded by "fine-ore passages" within the shell, whereby heat is intercepted and utilised for heating the fine ore. On their way to the heat zone, the coarse and fine ores are gradually mixed, the materials being discharged in common into the working chamber above the electrodes. The top of the furnace is provided with a plate, in communication with the passages by means of feed openings, and supplied with material by means of superposed hoppers, the walls of which are rigidly connected with each other and with the top plate. Dry carbonaceous material is fed through the central column, and the coarse and fine ore columns are also separated by means of carbonaceous material fed between them.—B. N.

Metals, ores, and the like; Method of working —. O. Frick, Salt-jöbaden, Sweden. U.S. Pat. 938,752, Nov. 2, 1909.

IN order to increase the power factor in the treatment of ores and metals, two electric furnaces of the transformer or induction type, differing appreciably in size and capacity, are arranged in communication with one another. The principal portion of the charge having been melted in the smaller furnace, the fused material is conveyed into the larger one, where it is refined or stored in the ordinary manner.—C. A. W.

XII.—FATTY OILS, FATS, WAXES, AND SOAPS.

Fat of beef animals; Composition of — on different planes of nutrition. I. C. R. Moulton and P. F. Trowbridge. *J. Ind. Eng. Chem.*, 1909, 1, 761–768.

FROM the results of determinations described in detail, the authors conclude that there is an intimate connection between the amounts of fat and of moisture and protein in the fatty tissue of animals, a high proportion of fat being associated with a low proportion of moisture and protein. The proportion of fat in the fatty tissue increases with the fatness of the animal, and that of the moisture with the leanness, the condition and not the age being the determining factor. The percentage of fat in the fatty tissue increases from the outside to the inside of the animal, whilst that of moisture decreases. The iodine value of the fat increases with the age and with the fatness of the animal, whilst the m. pt. decreases. A similar increase in the iodine value and decrease in the m. pt. in the fat takes place on proceeding from the outside to the inside of the animal, and there is a relationship between the two values, the one rising as the other falls. The sp. gr. of the fat varies with the iodine value, whilst there appears to be a similar relationship between the m. pt. and the saponification value.—C. A. M.

Castor-oil seed from Fiji. Bull. Imp. Inst., 1909, 7, 272–273.

THREE varieties were examined:—(1) "Fiji castor-oil beans, Mexican variety."—Small, dark-brown and mottled,

yielding 47.4 per cent. of oil; (2) "Fiji castor-oil beans, Mexican variety."—Large white seeds, mottled with dark brown, yielding 49.6 per cent. of oil; (3) "Fiji castor-oil beans, Hawaiian variety."—Medium-sized, dark brown, mottled seeds, similar to No. 1, but larger. Yield of oil, 48.5 per cent. The oil-content of castor-oil seeds usually varies from 46 to 53 per cent. The Fijian seed would probably realise from £9 to £9 10s. per ton in London.

—E. W. L.

Ground [arachis] nuts from Fiji. Bull. Imp. Inst., 1909, 7, 272.

OF the samples examined, some containing two kernels, were from 1.2 to 1.8 inch in length, and others, containing one kernel, from 0.8 to 1.1 inch. The kernels were from 0.6 to 1.0 inch long, and formed 75 per cent. of the total weight of the nuts; they yielded on extraction 49.1 per cent. of oil, a good average yield. The value of the nuts is estimated at approximately £14 to £15 per ton in London.

—E. W. L.

Fat from dadap (Erythrina hypaphorus) seeds. N. H. Cohen. Chem. Weekblad, 1909, 6, 777—784. Chem. Zentr., 1909, 2, 1576.

THE fat contains formic acid, oleic acid, linolic acid (yielding dihydroxystearic acid melting at 132° C. on oxidation with permanganate), palmitic acid, behenic acid (m. pt. 75° C.), sitosterol, and two other cholesterol apparently related to the stigmasterol and brassicasterol of Windaus. The sitosterol, $C_{27}H_{44}O + H_2O$, crystallised from alcohol in leaflets melting at 136.5° C. The anhydrous substance, in chloroform solution (0.596 gm. in 25 c.c.) had the specific optical rotation, $[\alpha]_D^{25} = -34.2$. An acetate, $C_{29}H_{46}O_2$ (needles, m. pt. 130° C.) and a benzoate (leaflets, m. pt. 146.5° C.) were prepared. The benzoate when melted and allowed to cool, exhibited a play of colours, owing to a change from one labile phase to another at 107°—108° C. (see also this J., 1907, 192, 1244).—A. S.

Fat and wax of tubercle bacilli; Chemical nature of the —. A. Fontes. Zentralbl. Bakter. u. Parasitenk., 1909, 1, Abt., 49, 317—321. Chem. Zentr., 1909, 2, 1763—1764.

TUBERCLE bacilli were extracted in succession with xylene, 95 per cent. alcohol, ether, and chloroform. The xylene extract when treated with alcohol yielded a precipitate which was soluble in ordinary fat solvents, and consisted of small, refractive, amorphous particles, which were stained by Zeihl's solution (1 gm. of fuchsin, 5 grms. of phenol, 10 grms. of alcohol, and 100 grms. of water); the coloration was not destroyed by acid. This substance proved to be a wax, the alcoholic constituent of which was different from cholesterol, isocholesterol, and phytosterol. The wax, which had an odour resembling that of tuberculin, melted at 53.5° C. and solidified at 52° C.; the portion soluble in ether melted at 54.5° C., and that soluble in chloroform melted at 193° C. and solidified at 191° C. The xylene-alcohol solution, after precipitation of the wax, was found to contain a fatty acid, probably palmitic acid.—A. S.

Extracted wax. O. G. Gabrilowitsch. Russ. Führer d.d. Fettind., 1909, 56. Chem. Zentr., 1909, 2, 1599—1600.

THE characters of Russian beeswax, as determined by the author, are shown in the following table:—

	Minimum.	Maximum.	Average of 100 analyses.
Sp. gr.	0.95	0.97	0.96
Melting point	60° C.	64° C.	62° C.
Acid value	18	22	20
Saponification value..	88	100	94
Ratio number	3.88	3.55	3.7

In the examination of crude Russian wax, complete saponification is not effected by boiling for 1 hour with alcoholic sodium hydroxide solution. For determining

the ester value, the author boils with alcoholic alkali three times for periods of 2, 3, and 4 hours respectively, and makes two separate determinations. In the case of extracted wax, heating for 4 hours on the sand-bath was necessary in determining the saponification value; the values obtained during the first hour amounted to 64—70, in the second hour 70—80, and in the fourth hour, 80—90. In applying Weinwurm's test for unsaponifiable matter (this J., 1897, 939) to extracted wax, it was necessary to boil for 3 hours with alcoholic potassium hydroxide. The author gives the following average values for extracted wax; sp. gr. 0.955; m. pt. 63.5° C.; acid value, 19; saponification value, 90; ratio number, 3.8. He recommends that the extraction process should be more largely used in Russia, pointing out that with the primitive method of separating the wax at present in vogue, large quantities are burnt in the form of waste.

Saponaceous neutral paste and process for the manufacture thereof. Soc. Nauton Frères et Co Marsac and T. F. Tesse, Paris. Eng. Pat. 9441, Apr. 21, 1909. Under Int. Conv., Mar. 10, 1909.

AN alkali sulphonate of castor oil is incorporated with an ordinary soap containing excess of alkali, to form a neutral paste with strong detergent properties. This paste may also contain an addition of a chlorinated hydrocarbon (preferably a chlorine derivative of ethylene or ethane) which has been rendered soluble or miscible with water by treatment with a sulphonated oil at a temperature near the b.pt. of the chlorinated hydrocarbon.—C. A. M.

Candle-making machinery. D. V. Plumbridge, London. Eng. Pat. 3559, Feb. 13, 1909.

THE melted wax is cooled in two stages, being first left in a plastic condition by passage through cooling tubes surrounded by warm water, and then, after introduction of the wick, passed through a tube cooled with cold water. The resulting solid bar with a central wick is then pressed in moulds to shape the candle ends. Claim is also made for a process of keeping the wax plastic, during the operations, by means of an electric current passed through wired asbestos rings arranged at suitable distances around the candle tube; also for the use of special movable compressors and blocks for moulding the plastic wax.

Paints and the like; Manufacture of vehicles for —
F. H. Walker, Bromley, Kent, and C. E. Sohn, London.
Eng. Pat. 2114, Jan. 28, 1909.

THE invention relates to the manufacture of a stable medium, suitable not only for blending with insoluble pigments but also for incorporating with oil-soluble and water-soluble colours. A mineral oil residuum is treated in the cold with a quantity of sulphuric acid sufficient to precipitate the asphaltic and resinous constituents. The treatment is preferably carried out in a mixer, with rotating and fixed arms. The mixture is allowed to separate, the oil is removed, and the residual tarry mass heated at 50° to 60° C. for a few hours, and then agitated with water and dilute caustic soda solution in small quantities at a time. An excess of fixed alkali must be avoided, and to this end the neutralisation may be completed by means of ammonia. By this means a completely homogeneous mass is obtained, which keeps indefinitely without visible separation of water. The mass mixes readily with oils to form fluid varnishes which can be incorporated with black or other dark pigments, and can be ground between steel rollers without losing their uniformity and smoothness. Such preparations are suitable for coating upon brickwork, wood, metal, textile fabrics, paper or other surfaces.—E. W. L.

(B.)—PIGMENTS, PAINTS.

Dammara viticenis [Agathis viticenis] resin from Fiji.
Bull. Imp. Inst., 1909, 7, 274-275.

THE resin consisted of a large mass of uniformly yellowish-brown material, opaque, with occasional semi-transparent streaks. It had a slight odour of turpentine oil, and contained a few small pieces of reddish bark. The following values were obtained:—ash, 0.06 per cent.; m. pt. (of the powdered resin in a capillary tube), 110°–115°C.; acid value, 157. The resin was partially soluble in turpentine oil and in benzene, completely soluble in a mixture of turpentine oil and alcohol, almost insoluble in ether, chloroform and alcohol. The resin therefore somewhat resembles Manila and Macassar copals, and may conveniently be known as Fiji copal. Its commercial value when scraped and cleaned is estimated at 30s. to 35s. per cwt. The masses of resin should be broken up into roughly cubical pieces of 1 in. to 1½ in. side, each piece examined and impurities removed. Outside pieces should either be well scraped or else sorted out from the rest and sold separately. Any "small" or "dust" resin should also be sold separately.—E. W. L.

Oil of turpentine; Analysis of —by bromination, and a method of determining bromine by means of sodium formate. Mansier, Ann. Chim. analyt., 1909, 14, 417-421.

THE method described is intended principally for the detection and determination of petroleum spirit in oil of turpentine. To 1 c.c. of the sample dissolved in 5 c.c. of chloroform and contained in a stoppered vessel are added successive quantities of bromine-water (containing 3 per cent. of bromine); after each addition, the mixture is well shaken and the end point of the titration is taken when a slight yellow colour persists for one minute. Pure oil of turpentine requires 1.69 grms. of bromine, or from 50 to 60 c.c. of the bromine-water, according to the strength of the latter; samples containing petroleum spirit require proportionally less. The bromine-water may be standardised by titration against a standard solution of sodium formate in the presence of zinc oxide, the latter being necessary to remove the hydrobromic acid formed by the reaction. Two atoms of bromine combine with 1 molecule of sodium formate.—W. P. S.

PATENT.

Lacquering or otherwise coating [metallic] surfaces.
W. W. Vincent, Kenosha, Wis. U.S.A. Eng. Pat. 21,593, Oct. 12, 1908.

THE heat necessary for stoving the lacquer (alcoholic

solution of shellac—English lacquer) applied to metal pieces such as the parts of a bedstead, is generated, according to the invention, in the metal piece itself, by the passage through it of an electric current. The metal piece is mounted in a lathe-like apparatus, the two supports forming the electrode, and a suitable current is passed until the piece is raised to a temperature sufficiently high to evaporate the volatile constituent of the lacquer as it is applied, but not high enough to injure the lacquer. The piece is suitably rotated, and the lacquer is applied. The several coats which it is necessary to apply, when using English lacquer, can be rapidly superimposed without damaging the underlying coats in any way.—E. W. L.

(C.)—INDIA-RUBBER, &c.

Rubbers from Southern Nigeria. Bull. Imp. Inst., 1909, 7, 255-260.

(1) *Funtumia elastica rubber.* Three samples were examined. Sample A consisted of rough sheets, colour from light to dark brown, clean and well prepared, exhibiting good elasticity and tenacity. Sample B was similar to A, but rougher and darker in colour. Sample C was prepared by natives. The analyses and valuations are given in the table.

	Sample A.	Sample B.	Sample C.
	per cent.	per cent.	per cent.

E. W. L.

Caoutchouc and gutta-percha. Condition of the industry in New Guinea. Verhandl. des Kolonial-Wirtschaftl. Komitees [Wirtschaftl. Ausschuss der Deutsch. Kolonialges.], 1909, No. 2, 34–44.

THE principal rubber plant cultivated in all the German

Colonies is *Hevea brasiliensis*, transplanted in the first instance from Ceylon. *Castilloa elastica* is only planted to a limited extent, as it is readily injured in tapping, whilst *Funtumia (Kickxia) elastica* is now only planted when sufficient *Hevea* cannot be obtained. On the other hand, the cultivation of the Ceara caoutchouc plant, *Manihot Glaziovii*, is extending in German East Africa, and the three new *Manihot* species, *M. dichotoma*, *pianhyensis*, and *heptaphylla*, appear to thrive in certain localities. The utilisation of the indigenous plants (*Kickxia*) by the natives is declining, and it is suggested that a system of instructing the natives and of premiums for the best plantations raised from seed might be instituted to check this decline. In the present condition of the market it might be profitable to extract the rubber from the latex of certain wild plants, such as "dead rubber," or *Gutta djeloton*, a member of the *Apocynaceae (Dyera)*, indigenous to the Malay Archipelago, although it only contains 10 per cent. of caoutchouc. In the forests near Alexishafen the yield of gutta-percha varies from 6 to 18 lb. per tree. The cause of the variation could not be determined. An expedition up the River Uaria reported the occurrence of gutta-percha trees in abundance. These were believed to be closely related to *Palaquium supfianum*, from which they differed, however, in having a paler and smoother bark. They also yielded less gutta-percha (5 lb. at most), and this was more resinous than the product of the other tree. The most economical method of tapping the trees was found to be by making a ring-formed incision with a hollow-ground gutta-percha knife. Caoutchouc trees were also plentiful in this district; they belonged to two species, *viz.*, *Parameria* and *Ficus*, the former yielding 0.5 to 0.75 lb. of caoutchouc, and the latter over 1 lb. per tree. The amounts of gutta-percha hitherto exported to Germany from New Guinea have been as follows:—

	Kilos.	Average price per kilo. Marks.
1907	660	2
1908	1510	1.70
1909	1830	2.30

The last consignments contained 30 and 31 per cent. of gutta-percha of the best quality, which was sold at 5.2 marks per kilo.—C. A. M.

Rubber production. Chem. Ind., 1909, 32, 694–695.

THE area planted with rubber trees in East Asia (Malaya, Ceylon, Java, Sumatra, Borneo and New Guinea, India, Burma) amounted to 495,000 acres in 1908 (this J., 1909, 99). By 1916 the production of rubber from this source will, it is estimated, amount to at least 50,000 tons. The total consumption of rubber if it increases at about the same rate as during the past 8 or 9 years will amount to 83,000 tons in 1916, after making allowance for regenerated rubber. The average production of rubber in Brazil during the years 1900–1907 amounted to 33,000 tons per annum, so that even if it does not increase, this supply, together with the 50,000 tons estimated production of East Asia, will cover the total estimated consumption in 1916. But rubber is now produced also in many other parts of Asia and America and in Africa, the total production from these sources being 25,000 tons at the present time. Even if this amount does not increase, the total production in 1916 would be 108,000 tons as compared with a consumption of 83,000 tons.—A. S.

PATENT.

Spongy rubber for tyres for wheels of carriages, motor-cars and cycles; Method of manufacturing —. E. Poizot. Fr. Pat. 401,303, July 17, 1908.

A MIXTURE of rubber (10 kilos.), sulphur (1 kilo.), and an alkali or ammonia solution (2.3 kilos.), with or without 10 kilos. of faktis (vulcanised oil), is heated in an autoclave for 1 hour under a steam pressure of 4 kilos. The proportion of alkali may be varied from 10 to 15 per cent. of the weight of the mixture according to the sponginess required.

—H. BR.

XIV.—TANNING, LEATHER, GLUE, SIZE.

Tanning; Theory of — W. Fahrion. *Z. angew. Chem.*, 1909, 22, 2083—2097, 2135—2144, 2187—2194.

The author considers that tanning depends upon chemical rather than physical processes, and that each tanning material has the chemical characteristic of an acid capable of forming peroxides in contact with air. The author has previously stated that, in every tannage, an oxidation of the hide fibre takes place and that leather should be termed "the salt of the oxidised hide-fibre," but at the same time suggested that further investigation should be made, and this article is the result of such further research. The subject is treated under four heads, *viz.*, chamois, aldehyde, vegetable, and mineral tannages, and the results of several experiments accompany the article.

Chamois tannage. The author defines chamois leather as the salt of the partially oxidised hide-fibre, as the base, with an unsaturated and partially oxidised fatty acid of fish oils. Referring to "Japan leather," which has been stated to owe its peculiar tannage to the action of a bed of almu underneath the river, in which the hides are treated (in Jakagimura, Japan), but which leather has been proved to contain only traces of alumina, and has been described as "leather without any tanning substance," the author states that "Japan leather" is similar to chamois, and that the tanning agent is the rape oil with which the hides are treated after immersion in the river. It might be assumed, that, because of its low iodine value, rape oil would possess very little leather-producing powers, but the author is convinced that it will form leather, and has shown by analysis of a pure rape oil and of an oil extracted from "Japan leather," that oxidation of the oil takes place in the process; he has further analysed the extracted oil, distinguishing several parts according to their solubility in alcohol, ether, and petroleum spirit. Experiments on the impregnation of hide with the fatty acids of various oils, showed that in the cases in which leather had been produced, the iodine value of the fatty acids had decreased and oxygen had been taken up. The author differentiates between fat-tannage and chamois-tannage by stating that in the former, the fat is worked mechanically into the pores of the fibre, whilst in the latter, oxidation of the tanning agent is necessary, and the more double linkages contained in the molecule of the tanning agent, the more intense the tanning. The author attributes the failure of a tanning experiment with turpentine oil to the absence of a carboxyl group and concludes by assuming salt-formation between the peroxy-acid of the fish oil and the hide substance, followed by oxidation of the hide fibre, in the chamois process.

Aldehyde tannage.—The author considers the aldehyde tannage analogous to chamois tannage, inasmuch as the basic group of the hide substance is primarily oxidised (perhaps only to a secondary amino-group) and then fixed.

Vegetable tannage.—The author's theory is that vegetable tanning materials are primarily oxidised to quinone-like substances, the latter being the real tanning agent, whilst the phlobaphenes have a filling and weight-giving effect.

Mineral tannage.—The author considers that the one-bath chrome tannage is neither a chemical process nor a colloidal precipitation process, but that the hide exerts a catalytic influence, whereby water is split off from the basic chromium salt in solution, thus leading to the formation of a slightly soluble anhydride which is precipitated in the hide. After neutralising the acid, the author continues, a chemical reaction takes place between part of the precipitated anhydride and the hide substance.

A good deal of the article is devoted to the criticism of the theories of other investigators, and the author discusses, in order, the physical and chemical properties of animal hides and of tanning materials and agents. He points out that hide has the power to adsorb colloids, without changing their chemical nature, to catalytically decompose water and to convert several oxygen-containing bodies into anhydride derivatives which are deposited upon the hide, immediately after their formation. The

presence of basic groups in hide substance enables it to form salts with acids and to undergo oxidation and condensation processes, similar to other amino-bodies. The author distinguishes between tanning materials and primary and secondary or "real" tanning agents, by stating that the tanning material may contain, besides the primary tanning agent, other matters which serve as "ballast," or influence the tannage in one way or another without being of chief interest. In many cases the primary tanning agent is changed into the secondary, by the oxygen from the air or water, the secondary agent reacting with the hide. The "real" tanning agent cannot be a colloid, as this would only act on the surface of the hide, and not penetrate to the interior. All tanning agents have one common characteristic; they contain oxygen atoms which form water with hydrogen atoms of other bodies. The author defines leather as animal hide which does not become hard and horny but remains soft and pliable after immersion in water and subsequent drying out; which does not putrefy in cold water, and does not form glue when boiled with water. He points out that although true tanning is mainly a chemical process, yet such physical processes as capillary attraction, diffusion, and adsorption are indispensable. In pseudo-tannage, which, though not a purely physical process, does not change the chemical nature of the hide, the hide substance acts as a dehydrating agent, changing the pseudo-tanning agent into amorphous anhydride derivatives, which are precipitated upon the hide. In conclusion the author reviews the methods and materials in use for the manufacture of the four above-mentioned classes of leather.—S. H.

Gelatin; A colour reaction of — R. E. Liesegang. *Z. Chem. Ind. Kolloide*, 1909, 5, 248.

WHEN a 40 per cent. solution of tricalcium phosphate and a 10 per cent. solution of copper chloride are allowed to diffuse through a gelatin film, and meet, a deep violet coloration, without any precipitate, is formed. When gelatin-jelly is added to a liquid containing precipitated copper phosphate, and allowed to stand overnight, the gelatin and the solution become violet, and the precipitate gradually becomes less in amount.—E. F.

Gelatin; Detection of traces of chlorides in — Lüppe-Cramer. *Z. Chem. Ind. Kolloide*, 1909, 5, 249—259.

SMALL amounts of chlorides in gelatin cannot be detected by the ordinary methods. If a 10 per cent. gelatin solution containing chlorides is allowed to solidify on a glass plate and a drop of 10 per cent. silver nitrate solution is then placed on the film, the portion of the film below the drop remains clear, but in the course of some hours an opalescent ring forms round the drop and becomes more and more opaque; it attains a diameter of 1 or 2 cm. In the presence of only 0.001 per cent. of sodium chloride, calculated on the dry gelatin, quite opaque white circles are obtained. If the resulting plate is afterwards exposed to the light, the white rings become greyish blue in colour and the colourless layer under the drop becomes reddish yellow, showing that silver chloride is present in both places, but in a very much more finely-divided form under the drop.—E. F.

PATENTS.

Leather; Dressing of — O. Silberrad. Buckhurst Hill, Essex. Eng. Pat. 22,869, Oct. 27, 1908.

THE leather is first thoroughly dried and then freed from all fatty matters by treatment with solvent-naphtha. It is then immersed in a 10 per cent. solution of rubber in solvent-naphtha for 24 hours. The leather is removed from the rubber solution, and when almost dry, the surface is freed from adhering rubber by rubbing with a cloth moistened with solvent naphtha, or by means of some suitable polishing machine.—H. BR.

Hides, skins, furs, etc.; Process of treating — H. R. Vidal. First Addition, dated Aug. 29, 1908, to Fr. Pat. 391,466, Aug. 29, 1907.

For the recovery of the paraffin wax resist employed

according to the main patent (see this J., 1908, 1150), the employment of carbon tetrachloride and carbon bisulphide as solvents is claimed. It is stated that the treatment with organic solvents imparts considerable suppleness to the hides or skins, whether these have been previously tanned or not.—A. S.

Tanning-drum arranged for suspending skins in a stretched condition. Vulcano Tanning and Machine Co. Fr. Pat. 400,940, March 17, 1909. Under Int. Conv., Nov. 17, 1908.

THE skins are suspended in a stretched condition from laths fixed in the periphery of the drum. The extremities, of the hide, which hang towards the centre of the drum are fastened by means of small hooks which project from the ends of the drum, thus keeping the hide in a stretched and fixed position throughout the tanning.—H. Br.

Hides, skins, and furs; Machine for the dressing and other treatment of —. F. E. Slocumb. Fr. Pat. 401,109, March 22, 1909. Under Int. Conv., Aug. 11, 1908.

THE machine consists of a perpendicular table, over which the hide to be treated is thrown. The table ascends between two brushes wetted with the liquid which it is desired to apply. The hide next meets a series of revolving plates which serve to impregnate the skin with the liquor, and finally a second pair of brushes which remove any surplus liquor.—H. Br.

Glue, its preparation and applications. C. Gillet. Fr. Pat. 400,831, June 26, 1908.

AN elastic glue may be obtained by adding glycerin to ordinary glue, or gelatin. The proportions vary according to the result required. The product can be used for giving flexibility to porous wood and also for gluing together strips of tissue.—H. Br.

XV.—MANURES, &c.

Soil nitrogen of Nebraska prairies; Relation of native leguminous plants to —. F. J. Alway and R. M. Pinckney. J. Ind. Eng. Chem., 1909, 1, 771–772.

DETERMINATIONS of the nitrogen in the air-dried leguminous plants collected from a measured plot of land typical of the virgin upland prairie of Eastern Nebraska gave results corresponding to 8.56 lb. per acre, whilst the nitrogen in the non-leguminous plants corresponded to 28.31 lb. per acre. It was estimated that the after-growth of the leguminous plants and those that had died before the date of collection might have increased the annual production of nitrogen by the aerial parts of the plants to 10 lb. per acre. Data from the growth of alfalfa on Nebraska soil indicated that the nitrogen in the roots was probably equal to that derived from the soil by the entire plant, and on this assumption the amount of nitrogen fixed by symbiotic bacteria would be about twice that added to the soil by rain and snow. The amount fixed by the non-symbiotic bacteria in the non-leguminous plants was estimated at about 8 lb. per acre each year. From a consideration of all these points, it was concluded that the amounts of nitrogen added to the soil by the three agencies—precipitation, symbiotic bacteria, and non-symbiotic bacteria—were probably approximately equal. Determinations of the nitrogen in the soil of this prairie were also made. Samples taken from different places in one field to a depth of six inches contained from 0.25 to 0.317

per cent. (average 0.284 per cent.), whilst from seven inches to six feet in depth, the amounts ranged from 0.240 to 0.042 per cent. In other fields the amounts down to 1 foot in depth varied from 0.153 to 0.465 per cent., whilst the average amount of nitrogen in 29 samples of the black soil deposited by summer floods on the lowland soils was 0.23 per cent. It was estimated that the first two feet of the soil in the upland prairies of eastern Nebraska contained about 10,000 lb. of nitrogen per acre, and the conclusion was drawn that this accumulation of nitrogen might be attributed to any of the three agencies mentioned. In the authors' opinion equilibrium has long been attained, and accumulation of nitrogen is now only to be expected in places where the original amount has been reduced by cultivation or natural erosion.—C. A. M.

Beetroot; Fertilisers containing manganese applied to the cultivation of the —. H. Roussel. Bull. Assoc. Chim. Sucr. et Dist., 1909, 27, 348–353.

MANGANESE is widely distributed in the soil and in plants, and Bertrand has shown that it is present in laccase, the oxydase activity of the enzyme being proportional to its manganese-content. It would appear, therefore, that manganese, in small quantity, must possess fertilising power. According to Grégoire, Hendrick, and Corpianx, addition of manganese sulphate to soil treated with superphosphate, sodium nitrate, and kainite, causes a slight decrease in the yield of beetroots, and a corresponding increase in the sugar-content of the roots, the yield of sugar being unaltered. Garola has investigated the effect of adding manganese chloride or sulphate (3.5 grms. of manganese per sq. metre) to an upland clay soil, on the crop of beetroots: it was found that the chloride and sulphate increased the weight of roots by 46 and 24 per cent. respectively; the former salt decreased the sugar-content of the roots from 8.6 to 7.3 per cent., whilst the latter increased it to 10.6 per cent.; the yields of sugar per sq. metre were increased from 378 grms. (without manganese) to 475 and 586 grms. with the chloride and sulphate respectively. According to Stoklasa, a fertiliser containing manganese increased the yield of sugar by 15–20 per cent. According to Gillin, manganese carbonate was found to have an effect similar to that observed by Grégoire with manganese sulphate; it was noticed also, that the manganese appeared to retard the fertilising effect of the sodium nitrate. It would be premature to prescribe rules for the use of manganese fertilisers, though the experiments made hitherto have yielded satisfactory results on the whole. The various combinations of soil, fertilisers, plants, and climate, must be taken into account. The manganese pre-existent in the soil is in the stable and inactive state of oxide. Manganese fertilisers should be used, as far as possible, in non-acid soils, and without regard to the manganese-content of the latter. Of manganese compounds, the sulphate appears to be most satisfactory though comparative experiments with other fertilisers should be made. Fertilisers containing lime and a small quantity of manganese oxides have been offered for sale; the oxides of manganese are useless as fertilisers. Nagaoka has shown that excess of a manganese fertiliser (more than 25 kilos., calculated as Mn_2O_3 , per hectare) is useless, a great excess being injurious. The manganese fertilisers should be mixed with the ordinary fertilisers in order to insure a uniform distribution on the soil; the materials chosen for admixture must be such that they do not interact with the formation of injurious compounds; a mixture of superphosphate, sodium nitrate, and manganese carbonate, is satisfactory in this respect.—L. E.

Formation of calcium cyanamide. Foerster and Jacoby. See VII.

PATENT.

Artificial manure; Manufacture of — from offal. J. Lehbauer, Connah's Quay, Flint, S. Mear, Longton, Staffs., E. W. Hollinshead and H. E. Moody, Tunstall, Staffs. Eng. Pat. 21,630, Oct. 13, 1908.

THE process consists in digesting offal with steam and acid

(cf. Eng. Pat. 23,045 of 1904; this J., 1905, 979) in tanks from which any solid matter deposited at the bottom can be ejected at intervals by means of a steam blast. The liquid obtained is delivered into the "valley" between two slowly rotating, steam-heated rollers, one of which is mounted in a sliding bearing, and is kept in yielding engagement with the other by means of a weighted bell-crank lever. The dried manure is removed from the surface of the rollers by scrapers having the form of weighted bell-crank levers. To facilitate the clearing of the obstruction when the rollers become clogged with imperfectly digested material, etc., a sliding door is provided in the frame-work of the rollers at one end of the "valley." When a block occurs, the door is opened by means of a screw-spindle, the liquid is discharged, and the lumps can then be withdrawn.—E. W. L.

XVI.—SUGAR, STARCH, GUM, &c.

Juices [Sugar]: Action of lime on crude . . . H. Pellet.
Bull. Soc. Chim. Sier. et Dist., 1909, 27, 354—357.

ACCORDING to Herles, the decrease in the polarisation of crude juice caused by the action of lime is due to alteration in the optical activity of certain substances present in the juice, but according to some chemists, the decrease is due to formation of insoluble calcium sucrate (see this J., 1908, 1168; 1909, 32). The view that this substance is formed by the action of lime at a high temperature, was not, at one time, accepted by the author, on the ground that it is not formed in pure sugar solutions under these conditions, but he now finds that the impurities present in the crude juice facilitate the formation of insoluble calcium sucrate, and that the precipitate formed by the action of lime on the non-sugars, prevents the insoluble sucrate from redissolving. Hence, according to the density and quality of the juice, and to the amount of lime added, a greater or less quantity of sugar is precipitated. Consequently, in studying the action of lime and of carbonation on the polarisation of juices, the procedure adopted should be identical with that which obtains in practice. According to several chemists, there is actually no appreciable decrease in polarisation by the action of lime and carbon dioxide upon diffusion juices under practical conditions, i.e., carbonation does not cause a decrease in the polarisation which can account for certain untraceable losses observed in some sugar-houses. According to Deltour, cold carbonation of the juice does not occasion any decrease in the polarisation, whereas hot carbonation causes a slight decrease, amounting to 0.06—0.09 per 100 c.c. of juices containing 11—13 per cent. of sugar. The author offers the following explanation of this small loss:—A small quantity of sugar is carried away with the escaping vapours during hot carbonation (compare this J., 1906, 437), and the lime does act on certain non-sugars in the hot juice, these substances, which are present in small quantity, yielding a less dextro-rotatory product. Since sucrose is precipitated from crude juice in presence of lime, and in spite of the addition of a considerable quantity of basic lead acetate, it seems advisable to avoid the use of basic lead acetate in the determination of sugar in the muds.—L. E.

Sugars: Decomposition of the —. VI. Electrolytic reduction of dextrose. W. Löb. Biochem. Zeits., 1909, 22, 103—105.

IN the third communication of this series (this J., 1909, 535), the author advanced a scheme according to which, in the electrolysis of dextrose around a lead anode, the decomposition of the dextrose, and the formation of acids by oxidation, are regarded as primary and secondary processes respectively. It might be supposed that the formation of a pentose and formaldehyde is due to oxidation. Theories previously advanced concerning the reversibility of sugar-synthesis (this J., 1909, 1068), and other theories shortly to be published, necessitate experimental proof that the oxidising action at the anode only destroys the equilibrium.

and thus causes an accumulation of pentose and formaldehyde (these products, like the dextrose, becoming oxidised in part). The author has now furnished the proof. Dextrose was electrolysed under conditions similar to those previously described (*loc. cit.*, 535), save that the current was passed in the opposite direction, i.e., the leaden worm was made the cathode. Under these conditions, 0.0027—0.0097 gm. of formaldehyde and 0.15—0.17 gm. of pentose were obtained from 20 grms. of dextrose. The melting point and microscopic appearance of the osazone of the pentose were the same as those of the osazone of the pentose obtained with the lead as anode. Hence, both the hydrogen and the oxygen liberated in electrolysis, destroy the equilibrium above referred to, and cause an accumulation of pentose and formaldehyde.—L. E.

Formaldehyde: Supposed formation of — on boiling solutions of sucrose. C. H. La Wall. Amer. J. Pharm., 1909, 81, 394—396. (Chem. Zentr., 1909, 2, 1736—1737. (Compare Ramsay, this J., 1908, 1218.)

THE author finds that when solutions of sucrose are boiled under ordinary conditions, no formaldehyde is produced. Furfural is formed and this reacts in a similar manner to formaldehyde in Hehner's test (this J., 1895, 772; 1896, 382), but has no influence in Fimini's test (this J., 1898, 697, 1076). The presence of furfural was detected by means of aniline acetate solution (Bull. No. 110, U.S. Dept. Agric.), with which formaldehyde gives no reaction.—A. S.

Maple sugar and syrup: Suggested standards for—.
H. W. Cowles, jun. J. Ind. Eng. Chem., 1909, 1, 773—774.

MAPLE sap when concentrated to a syrup yields an insoluble deposit termed "nitre," which consists in the main, of calcium salts. The syrup separated from this deposit invariably contains over 0.45 per cent. of ash, and when further concentrated to sugar will yield an ash of about 0.65 per cent. calculated on the anhydrous substance. In certain samples prepared during the last season the "nitre" had not been removed, so that it was possible to add cane sugar to these and still have a sugar with an ash in excess of the U.S.A. standard of 0.65 per cent., but which on dilution and filtration would not give a syrup yielding the legal proportion of ash. The following results were obtained in the analysis of samples of pure maple sugar and of syrups prepared from them by the addition of 25 c.c. of water to 50 grms. of sugar, followed by filtration:—

	Moisture, per cent.	Ash.		Alkalinity of ash per 100 grms.	Ash on dry substance, per cent.	Ash on syrup basis 32 per cent. water), per cent.
		Total, per cent.	Insoluble in water, per cent.			
Maple sugar, New York	2.70	1.116	0.724	181.0	1.147	0.80
.. .. SYRUP	11.28	0.455	0.141	79.0	0.775	0.527
Maple sugar, Canadian	6.1	0.861	0.476		0.917	0.624
.. .. SYRUP	39.44	0.476	0.175	75.0	0.786	0.554

The following standards are suggested for these products :—Maple sugar is the solid product from the evaporation of maple sap or maple syrup. It should contain not less than 0.65 per cent. of maple sugar ash, calculated on the anhydrous substance, and yield a clarified solution of maple syrup containing not less than 0.45 per cent. of maple syrup ash. Maple syrup should contain not less than 0.45 per cent. of maple syrup ash, and not more than 34 per cent. of water.—C. A. M.

Potatoes ; Manufacture of starch from sweet — C. C. McDonnell. S. Carolina Agr. Exp. Sta., 1908. Bull. No. 136, 7—50.

THE varieties of the sweet potato (*Ipomoea Batatas*) richest in starch, contain, on the average, about 22 per cent. of this constituent. Of the varieties examined by the author, Providence, Southern Queen, and Triumph appear to be most suitable for the manufacture of starch. The author describes experiments on the extraction of starch from these, and a fourth variety—Red Nansemonde—and on the behaviour of the product towards bleaching agents. All the starch preparations were found to be of a good grade chemically, and the results of practical tests in laundry work, and in the textile industry, were satisfactory in every case. The residual pulp, which still contains a considerable quantity of starch, constitutes a good fodder for stock. The waste water from the settling tank, which contains all the soluble matter of the potato, including some nitrogenous organic matter and salts of phosphoric acid and of potash, could be used for irrigation purposes in many cases. It would no doubt, be more profitable, however, to mix the first wash water, which would contain practically the whole of the sugars, with the pulp, ferment the whole, and recover the alcohol by distillation. Further data will be required in order to settle the question as to whether the manufacture of starch from sweet potatoes can be made a commercial success. The present price of sweet potatoes would not permit it, but in growing the potatoes on the scale necessary to supply one or more starch factories, a number of expenses could be eliminated. The author suggests that the whole crop of potatoes should be taken over from the farmer by the factory. The best and even-sized potatoes should be sold for table use, or canned, whilst the small, over-sized, and ill-shaped potatoes should be worked up in the factory. The author also points out that a successful method has been devised for drying sweet potatoes. The desiccated potatoes will keep indefinitely, and may be sent long distances at comparatively small cost.—L. E.

Cassava starch from Fiji. Bull. Imp. Inst., 1909, 7, 271—272.

THE sample was of high purity, clean and white, and free from visible impurity, taste and smell. It contained starch, 84.8; moisture, 14.9; and ash, 0.2 per cent. Cassava starch appears to be unsuitable for laundry purposes, but quite suitable for glucose manufacture, for which purpose it would be worth not more than £8 per ton on the English market. It could also probably be employed as a substitute for sago, but not for potato-starch in sizing cotton yarns, and as a dressing or finish for fabrics. For general purposes, as a manufacturing starch, it would probably fetch about £14 to £15 per ton if placed on the English market in quantity.—E. W. L.

XVII.—BREWING, WINES, SPIRITS, &c.

Malt ; Influence of various methods of mashing on the amount of extract yielded by — W. Windisch, E. Bieckhoff, and A. Stadel. Woch. f. Brau., 1909, 26, 593—598.

WHEN first selected as the standard method the "Congress"

process of determining the extract yielded by a malt gave values exceeding those obtained on the practical scale, and such values were spoken of as the "theoretical" yield of a malt. In recent years the brewhouse practice has advanced to such an extent that yields exceeding those of the Congress method are commonly obtained, and the latter are now spoken of as "laboratory" yield. Thus the figures obtained for the extract of a malt by the Congress method cannot nowadays be taken as the standard which the brewhouse should strive to emulate, and the authors have sought to devise a series of laboratory processes by which the highest possible extract of a malt can be secured. Eleven malts of various descriptions, ranging from very under-grown to well-modified, have been mashed by each of twelve methods, which include the standard Congress process and proteolytic mashing alone and in combination with 12 hours pre-mashing at ordinary temperature, and with three-quarters of an hour's heating under 2 atmospheres pressure. The results are given in tables and in curves which show that in every case the highest yield has been obtained by a combination of pre-mashing, proteolysis and heating under pressure carried out as follows: the malt is mashed with cold water, allowed to stand for 11—12 hours (overnight), heated and maintained for half an hour at 45° C., raised to 50° C. and, after half an hour, part of the liquid withdrawn; the mash is raised to 70° C. for conversion and afterwards heated for 30 to 35 minutes at 2 atmospheres pressure, and then cooled to 50° C. The wort withdrawn is now returned and the mashing completed according to the Congress method. This method is suggested, tentatively, as a workable substitute for the Congress process, as yielding values by which the brewhouse working could be checked.—R. L. S.

Pentosans ; The behaviour of — in malting and mashing. W. Windisch and G. Van Waveren. Woch. f. Brau., 1909, 26, 581—585.

THE question of the importance, or otherwise, of the pentosans in beer has been recently revived by the discussions that have arisen over the value, to the brewer, of the increased yield of extract obtainable from malt by pre-mashing methods. It has been shown that such methods increase the amount of pentosans extracted from malt, and as certain untoward results obtained with worts prepared by them have been ascribed to the increased content of pentosans, the authors have investigated the subject thoroughly. They find that barley loses during steeping a notable amount of pentosans dissolved from the husk. During malting an increase of the soluble pentosans occurs, so that well grown malt is richer in these substances than a poorly grown malt from the same barley. This difference persists in the worts from the two kinds of malt. Pre-mashing malt leads to the presence of more pentosans in the wort, but the wort prepared by ordinary methods from a well-grown malt contains more of them than does the wort yielded by pre-mashing a short grown malt from the same barley. During fermentation pentosans are not attacked and are recoverable quantitatively from the finished beer; they are flavourless substances, and, in the proportions in which they occur, cannot be regarded as detrimental. The authors conclude that the causes of the loss of character frequently observed when pre-mashing methods have been adopted must be sought elsewhere.—R. L. S.

Fermentation process ; Removal of infection in the continuous — E. Lühder. Z. Spiritusind., 1909, 32, 485—487, 496—497.

THE author has made experiments with the object of ascertaining whether the yeast-infection which occurs from time to time in a distillery working with continuous fermentation can be removed, so that renewal of the yeast may be avoided. Potato-mashes saccharified by malt were employed, and continuity of the fermentation was effected by mixing one-third of a fermenting mash with twice its amount of fresh mash, the remaining one-third of which was run into the already fermenting mash. In the first series of experiments, the normal acidity of the mash was increased by the addition of small proportions of sulphuric acid. The first mash yielded 9.9 per cent. of

alcohol and had a final acidity of 0.73°, whilst the sixth mash gave only 8.2 per cent. of alcohol and exhibited an acidity of 1.6°. An attempt to check the infection causing this increased acidity by adding an augmented proportion of sulphuric acid met with failure, the seventh mash yielding only 7.4 per cent. of alcohol and possessing a final acidity of 1.65°. One-third of this mash was then mixed with sufficient sulphuric acid to raise the total acidity to 2.85° and left for two hours at the ordinary temperature. This treatment resulted in the destruction of nearly all the bacteria present, whilst only 5–10 per cent. of the yeast-cells were killed. The use of the purified yeast in a new mash resulted in a yield of 9.3 per cent. of alcohol and no increase in the acidity. A similar purification of an infected yeast was effected by adding hydrochloric acid so as to bring the total acidity to the value 2.85°. The multiplication of the yeast, which is found to diminish with increase of infection, is about 3:1 under normal conditions, but with the yeasts purified by sulphuric and hydrochloric acids, it reached the values 5.24:1 and 3.87:1 respectively. In the continuous fermentation process, it is important that, after pitching, the mash should contain a large proportion of yeast. Purification of the yeast by means of sulphuric or hydrochloric acid should be undertaken as soon as a mash is found to exhibit an appreciable increase of acidity during the first 24 hours after the commencement of fermentation.—T. H. P.

Fermentation process; Continuous — with mineral acids.
Bücheler. Z. Spiritusind., 1909, 32, 511.

THE author describes a distillery system of continuous fermentation which has been in operation about a month and in which proportions of sulphuric acid are employed sufficient to raise the initial acidity of the mash from zero to 0.2°. The mash is pitched with only one-fifteenth or one-twentieth of the preceding mash, the proportion used by Lühder (see preceding abstract), namely, one-third, being regarded as unnecessarily large.—T. H. P.

Tartaric acid from residues of wine manufacture; Recovery of —. A. Janson. Chem. Ind., 1909, 32, 719–722.

GRAPE musts contain 5–8 per cent. of crude tartar, whilst the wine on an average contains only 2 per cent.; thus the residues from a hectolitre of wine contain about 600 grms. of crude tartar. A portion of this adheres to the sides and bottom of the fermentation and storage tuns as a very hard crust, which may be removed periodically. Some considerable care is necessary to remove this crust without injury to the tuns. Small quantities of tartar are recovered when the tuns are rinsed out, the waters being collected and the heavier tartar separated from the lighter suspended matter by settling. The tartar contains, besides potassium hydrogen tartrate, considerable proportions of calcium tartrate, depending on the origin and treatment (e.g., neutralising or "plastering") of the must. In Germany, the Main and Saale wines are particularly rich in calcium. In recent years the grape mares and yeast have been specially treated for the recovery of tartar. The mares contain 3–5 per cent.; they are richer in the more northern districts. As a rule it does not pay to treat mares which have been pressed out from the sweet musts before fermentation, but red wines are always fermented

with the mares. The recovery of tartar from the mares may be combined advantageously with the distillation of brandy. The hot vinasse may be separated as quickly as possible from the mares and allowed to cool slowly in vats. A higher yield of large crystals is obtained by diluting the liquid with water and boiling for some time, twigs or threads being suspended in the crystallising vats. The mares themselves should then be boiled with water (120 litres per 100 kilos. of mare) and pressed. According to another process the mares and vinasse are allowed to cool together; the clear liquid is run off and the mares are dried, the crystals of tartar being separated by threshing. A similar system may be employed for the liquors themselves, by straining them through cloths and drying the deposit thus collected. A further quantity of tartaric acid may be obtained from the clear mother liquors by neutralising with lime and collecting the precipitate of calcium tartrate. Another process consists in boiling the separated mares with hydrochloric acid, straining, and carefully neutralising the filtrate with lime. This process, however, gives a product highly contaminated with organic matter, and the residual mares are no longer available for fodder. The yeast also may be treated for the recovery of tartaric acid. It is pressed and, in some cases dried, before despatch to the chemical works. Well-pressed yeast contains, on the average, 25 per cent. of tartar, chiefly calcium tartrate. The yeast from sweet-pressed musts contains more than that from red wines. The recovery of tartaric acid from yeast, whether direct or after distillation, is best effected by boiling with acid; 600 grms. of crude hydrochloric acid are sufficient for the extraction of 1 kilo. of tartar. Lead-lined tanks are employed; the neutralisation of the acid filtrate must be effected with the greatest care to avoid either a deficiency or an excess of lime or chalk. The dried precipitate contains about 80 per cent. of calcium tartrate and the residual yeast is available for manure.—J. F. B.

Ethyl alcohol; Electrolytic oxidation of — to acetic acid. P. Askenasy, R. Leiser, and N. Grünstein. Z. Elektrochem., 1909, 15, 846–860.

THE authors have investigated the conditions necessary for obtaining the best yield of acetic acid by the electrolytic oxidation of alcohol, and consider that, with cheap power, using fermented beetroot juice as the source of alcohol, the process might successfully compete with the existing method of manufacturing acetic acid; a table showing details of the probable cost of production (in Germany) is given. Some aldehyde and ethyl acetate are formed during the process of electrolysis, the latter becoming hydrolysed as the alcohol is used up, and towards the end of the oxidation, acetic acid is decomposed with the evolution of carbon dioxide. In the experimental cell employed, no diaphragm was used, the electrodes being placed only 3 mm. apart, and a little sulphuric acid added to the diluted alcohol. The best results were obtained when about 2 grms. of chromium sulphate per litre of electrolyte were added as an oxygen carrier. Sodium acetate, contaminated only with sodium sulphate, was obtained by evaporating the neutralised electrolyte. The results are summarised in the following table:—

	Temperature C.	Current- density, ampères per sq. dm.	Potential, volts.	Current yield, per cent.	Yield of substance, per cent.	Kilowatt-hours per kilo. of acid.

XVIII.—FOODS; SANITATION; WATER PURIFICATION, AND DISINFECTANTS.

(A.)—FOODS.

Creatinine [in meat extracts, etc.]; Jaffé's colorimetric method for the determination of —. A. C. Chapman. Analyst, 1909, 34, 475–482.

The coloration produced when a solution of creatinine is added to a solution of sodium or potassium picrate containing an excess of alkali, is due to the reduction of the picric acid and not to the formation of creatinine picrate. The author shows that the reduction proceeds beyond the formation of aminodinitrophenol (picramic acid) and that the coloration is due to the presence of several reduction products; this applies when the picric acid is present in excess, but when creatinine is in excess, the picric acid is reduced completely to triaminophenol. A number of experiments carried out with the object of ascertaining what influence variations in the proportions of picric acid and alkali have on the determination, yielded results which confirmed the conclusions arrived at by Emmett and Grindley (this J., 1908, 87). The reacting solutions should be maintained at 20° C., or other convenient temperature, as the temperature factor is of considerable importance; up to a certain point, the colour is intensified with an increase of temperature, after which there is a reduction due to the formation of triaminophenol. Slight variations of the time during which the solutions of creatinine and alkaline picrate are allowed to interact have but little influence on the results, the tendency, however, being in the same direction as in the case of the temperature factor. The presence of dextrose is without appreciable effect. As regards the comparison solution used in the determination, the author favours the employment of a fixed standard, such as the bichromate standard. The following details are given for the application of the method to the determination of creatine and creatinine in meat extract: A 10 per cent. solution of the meat extract is prepared; several portions (10 c.c.) of this solution are then placed in small beakers, 10 c.c. of *N*/1 hydrochloric acid are added to each, and the beakers are then heated in an autoclave for 30 minutes at a temperature of 120° C. To the contents of one of the beakers, cooled to 20° C., 30 c.c. of a saturated solution of picric acid and 15 c.c. of a 10 per cent. solution of sodium hydroxide are added, and, after the lapse of 5 minutes, the coloured liquid is diluted to a volume of 500 c.c. This solution is then matched against 8 mm. of the standard bichromate in the cylinders of a Dubose colorimeter. From the reading obtained, a simple calculation will show approximately the volume to which the contents of another of the beakers must be diluted in order to give a reading in the colorimeter between 7 and 10 mm. The quantity of total creatinine is then readily ascertained. The creatinine present as such in the meat extract may be determined by ascertaining the dilution necessary for matching, by means of a preliminary reading, with an aqueous solution purposely made too strong.—W. P. S.

Milk; Decomposition of hydrogen peroxide by —. E. Kohn-Abrest. Ann. Chim. analyt., 1909, 14, 415–417.

RESULTS of experiments are given showing that milk, after having been exposed to the air for about 5 days, ceases to decompose hydrogen peroxide (as shown by the guaiacum test), but is still active at the end of 15 days when kept in a closed vessel. Milk curdled by the addition of lactic acid behaves similarly. The catalase is found in the serum of milk which has been curdled by means of lactic or acetic acids; the curd, after being washed, is practically inactive. Heat, the presence of alcohol or acids, contact with air, or storage under low pressure, all inhibit or interfere with the action of the catalase.—W. P. S.

Casein; Volumetric determination of — in milk. L. L. Van Slyke and A. W. Bosworth. J. Ind. Eng. Chem., 1909, 1, 768–771.

THE following method is recommended as being simpler and more rapid than that of Matthaïopoulos (Z. anal. Chem., 47, 492) whilst giving as accurate results:—A definite quantity (20 c.c.) of the milk is diluted with 80 c.c. of water, and neutralised with sodium hydroxide solution, using phenolphthalein as indicator. An excess of alkali may be avoided by comparing the tint with that of a colour standard prepared with 20 c.c. of skimmed milk and 80 c.c. of water, and coloured a faint but distinct pink with a dilute carmine ink. This may be preserved with mercuric chloride and kept for future comparisons. As a rule from 3 to 4 c.c. of *N*/10 alkali solution are sufficient to neutralise fresh milks. The neutralised liquid is next treated with *N*/10 acetic acid, added 5 c.c. at a time at a temperature of 18° to 24° C., and the flask is shaken at intervals. The amount of acid (A) required for complete precipitation of the casein is noted, the liquid made up to 200 c.c., and the precipitate filtered off. An aliquot portion (100 c.c.) of the clear filtrate is then titrated with *N*/10 sodium hydroxide solution, and the difference between the result (B) and half the amount of A, multiplied by the factor 1.0964, gives the percentage of casein. The results thus obtained should agree within 0.2 per cent. of those given by the official (Assoc. Official Agric. Chem., U.S.A.) method. Fresh milks preserved with mercuric chloride in the proportion of 1:1000 or 1:1500 give satisfactory results after having been kept for 2 or 3 weeks.—C. A. M.

Flour; Use of coal-tar oil in the examination of —. L. Loviton. Ann. Chim. analyt., 1909, 14, 412–413.

IF any flour be treated in a test-tube with benzol or other colourless coal-tar oil, the starchy portion of the flour is rendered so transparent that it seems to disappear, whilst the bran and other coloured constituents are seen floating in the liquid. This test will be found to be of use in comparing one flour with another, as the comparison is much more readily made than when the two flours are examined side by side without treatment. Five grms. of flour and 10 c.c. of benzol are convenient quantities to employ.—W. P. S.

Saccharin and other artificial sweetening agents; Detection of — in food and beverages. A. Bianchi and E. di Nola. Ann. des Falsific; through Bull. comm., 1909, 37, 479.

THE liquid under examination is freed by evaporation from any alcohol present; acidified with acetic acid, 20 drops for every 100 c.c., and treated with normal lead acetate solution in excess. After standing for 30 minutes, excess of a 1:5 solution of sodium sulphate containing the same amount of sodium phosphate is added, and the precipitated lead salts are removed by filtration. The filtrate is concentrated to a small volume on the water-bath, and acidified with dilute (1:2) sulphuric acid. It is then shaken with a mixture of equal volumes of ether and pure benzene. On evaporating the benzene-ether extract, saccharin and its ammonium compound, dulcitol or sucramine, will leave a sweet residue. If salicylic acid should accompany the saccharin, this

must be eliminated by oxidising the residue with permanganate and sulphuric acid. The oxidation liquid is then again shaken with the benzene-ether solvent. Saccharin, if present, remains unoxidised, and can be detected in the benzene-ether residue.—J. O. B.

Grain; Process and apparatus for the treatment of — [for increasing its suitability for baking purposes]. J. G. E. Dombach, Amsterdam. Eng. Pat. 25,193, Nov. 23, 1908.

A portion of the grain, such as wheat, rye, or oats, is subjected, before being ground, to a swelling process, which is stopped before actual germination commences. This treated portion is then added to the main bulk of the grain. The bulk of the grain is washed, dried and cooled, whilst the small portion, to be subjected to the swelling treatment, is washed in a number of vessels provided with discharge valves and sieves at their lower parts and also with means for supplying air under pressure below the mass of the grain. A number of these vessels are fitted up adjacent to each other so that grain in varying stages of swelling may be under treatment at the same time.—W. P. S.

Seed; Metabolism of —. J. von der Kammer, Washington, D.C., U.S.A. Eng. Pat. 8131, April 5, 1909. Under Int. Conv., June 12, 1908.

THE metabolism of seeds and the growth of plants therefrom may be accomplished without soil, by treating them in an anaerobic chamber (see Eng. Pat. 8130 of 1909) and moistening periodically with an artificial nutriment. An anaerobic gas, preferably nitrogen, is introduced into the chamber to assist the process. Plants so treated and used as stock food for cattle, produce a marked improvement in the quality of the meat.—H. Br.

Cream to be used in the production of butter; Process of improving the flavour of —. H. C. Buer, Cologne-Marienburg, Germany. Eng. Pat. 18,201, Aug. 6, 1909.

FROM 2 to 5 per cent. of lecithin is added to fresh cream and the mixture is kept at a temperature of from 12° to 15° C. for from 20 to 30 hours. The lecithin is reduced by bacterial action with the production of considerable quantities of "butter flavour or aroma."—W. P. S.

Milk; Process of utilising dried —. A. L. Just and B. Stolz, Executors of J. A. Just, Syracuse, N.Y. U.S. Pat. 939,138, Nov. 2, 1909.

A RECONSTITUTED milk may be prepared by dissolving dried milk in water, inoculating the solution with aroma-producing organisms, and keeping the mixture at a suitable temperature until an aroma like that of ordinary milk is developed. The action of the organisms is then arrested and a soluble calcium salt is added.—W. P. S.

Sweet cakes for feeding cattle; Manufacture of —. J. B. E. Fabre, London. Eng. Pat. 18,773, Aug. 14, 1909. Under Int. Conv., Jan. 28, 1909.

ONE or two parts of concentrated molasses or syrup water (95° to 98° Brix) are mixed with one part by weight of dry beetroot slices, malt grains, chopped fodder, or the like. The mixing is carried out in a suitable apparatus provided with a heating jacket, and the mass is then poured into moulds to cool. The foodstuff thus obtained consists approximately of: water, 8 to 10; albuminoids, 4 to 5; non-nitrogenous matter, 70 to 75 (of which 35 to 40 are sugar); cellulose, 8 to 9; mineral matter, 5 to 6; and fatty substances, 0.2 to 0.3 per cent.—W. P. S.

(B.)—SANITATION; WATER PURIFICATION.

Trade effluents; Treatment of —. Local Govt. Officer, Nov. 27, 1909. [T.R.]

THE discharge from the manufactories into the sewers continues to receive a considerable amount of attention by the Manchester Rivers Department, and much good has been done in this direction. In a number of cases manufacturers have been required to stop discharges of dangerous and potentially dangerous effluents, heated liquids, and discharges containing excessive solid matters in suspension. Offenders, in several instances, found compliance with the Committee's requirements very beneficial to themselves, as the precautions taken resulted in the detection of much avoidable waste. A striking case may be quoted of an effluent to which exception was taken by the Committee, and from which there is now recovered by the improved methods adopted nearly 40,000 galls. of oil per annum, which formerly entered the sewer. In achieving this result it has been found possible to reduce the working expenses sufficiently to pay, in a few years' time, for the new filtering arrangements, apart altogether from the value of the oil recovered. Some time ago, owing to the discharge from a chemical works of liquids containing sulphides in solution, a particularly offensive nuisance occurred in the city sewers, when several miles were filled with sulphuretted hydrogen. Upon being informed of its nature, the owners pleaded ignorance, and at once stopped the offending discharge. However, owing to the serious character of the offence, the Committee, in the public interest, had no alternative but to take proceedings, the result being the infliction of a fine.

PATENTS.

Water purifiers. E. C. R. Marks, London. From Oliver-Roche Co., New York. Eng. Pat. 27,270, Dec. 15, 1908.

THE apparatus consists essentially of a settling tank in which is placed a filtering chamber; the latter rests on beams placed across the bottom of the settling tank, and the bottom of the filter chamber is constructed of a galvanised iron screen. The latter supports a layer of granular carbon above which is placed a brass screen on which are spread layers of sand. The water enters the settling tank through a small chamber provided with a sieve which removes suspended matters from the water. It rises in the settling tank, and flows upwards through the screens and filtering materials and is drawn off from the filtering chamber at a point above the upper layer of sand. The iron and brass screens act as electrodes, the water itself being the electrolyte. As the filter becomes clogged, the level of the water rises in the settling tank and the increased pressure thus produced causes the filter to continue working. Several filter chambers may be placed in one settling tank, means being provided so that when one filter becomes clogged, the water is conducted to another unit. Chemical reagents may be added to the water as it enters the settling tank. (See also Eng. Pat. 27,271 of 1908; this J., 1909, 1161).

—W. P. S.

Water; Process of purifying —. J. W. Morrison, Assignor to Steam Appliance Manufacturing Co., Batavia, N.Y. U.S. Pat. 938,779, Nov. 2, 1909.

THE water is heated under pressure to a temperature exceeding 300° F., and the precipitated substances are then removed by filtration while the water is still at a high temperature. The hot, filtered water passes through a chamber where it yields up its heat to cold water which is being conducted to the heating vessel.—W. P. S.

Sewage water; Mechanical filtration of —. E. Geiger, Karlsruhe, Germany. Eng. Pat. 16,837, July 19, 1909.

IN order to separate the solid from the liquid part of sewage, a wheel, which is provided with sieve-like scoops, is fixed in the sewage canal and revolves in the opposite direction to the flow of the sewage. The solid matter is collected on the scoops and is gradually moved to the

centre of the wheel where it is discharged. Any mud which adheres to the sieve is swept off by means of brushes, and is also brought to the discharging device.—H. Br.

XIX.—PAPER, PASTEBOARD, &c.

Cellulose [in lignified materials]; Methods for determination of —. M. Renker, Dissertation, Berlin, 1909, 1—106.

THE author's investigations fall under two heads: the determination of hygroscopic moisture in cellulose, and the determination of cellulose in lignified materials. There is no definite line of demarcation between the expulsion by heat of hygroscopic moisture and the expulsion of moisture owing to decomposition or dehydration of the cellulose itself. The former gradually merges into the latter as the temperature is raised, until visible discoloration takes place at about 150° C. The rate of decomposition varies with the nature of the cellulose and is lowest in the case of cotton. The term, "absolutely dry," is therefore more or less conventional, and is taken to represent the arrival at constant weight in a toluene drying oven at a temperature of 105°—107° C. At this temperature the degree of saturation of the external air has a slight influence, which is negligible for practical purposes. Contrary to Hofmann (this J., 1907, 942), the author was unable to detect any chemical change in sulphite wood pulp dried under these conditions, but cellulose which had been over-oxidised or otherwise altered by chemical treatments showed marked signs of decomposition. Cellulose spread out in a desiccator over phosphorus pentoxide arrives at the "absolutely dry" condition at the ordinary temperature after 3—4 weeks; the time of exposure may be curtailed to about 20 hours by maintaining a good vacuum. This is the best

The raw materials taken for the study of the methods for the determination of cellulose consisted of unbleached sulphite wood pulp, jute "half-stuff" prepared in a paper mill, thin shavings of white-lir wood, and raw cotton. These materials were further purified, before analysis, by extraction with boiling water and a mixture of alcohol and benzene. Of all the methods investigated none was found worthy to stand in comparison with Cross and Bevan's method of chlorination (see "Cellulose," p. 95; also J. Chem. Soc., 1882, 41, 105); many indeed did not yield cellulose at all. Nevertheless the chlorine method shows in a minor degree, the errors inherent in the other practicable processes, viz.: it is necessary to choose between an imperfectly purified cellulose on the one hand and a loss of cellulose, under the attack of the reagents used, on the other. This error is negligible in the case of not very highly lignified materials such as sulphite pulp, cotton, and even jute, but it becomes appreciable in the case of wood. The celluloses derived from the more highly lignified materials are also more sensitive to the attack of the reagents. The destruction of the cellulose may be curtailed by omitting the preparatory boiling with alkali, maintaining the temperature at 0° C., restricting the time of exposure to chlorine gas as far as possible, and immediately flooding the chlorinated material with a solution of sulphurous acid. The author found it impossible to prepare a pure cellulose from wood, with less than six chlorinations (compare Dean and Tower, this J., 1907, 988), and the cellulose undoubtedly suffered thereby. A pure jute cellulose prepared by a single chlorination, lost 2 per cent. in a second treatment and a further 0.9 per cent. in a third treatment. The method depending on oxidation by permanganate in presence of 5N-acetic acid yields very good results for the determination of pure cellulose in sulphite wood pulp and cotton, and even removes the whole of the lignin from jute; the yields are satisfactory but the cellulose is somewhat over-oxidised; the method is useless in the case of wood. H. Müller's bromine method yields fair results and a pure product, but is far too tedious for practical purposes. Schulze's method (see Henneberg, Annalen, 1868, 146, 130) and Hoffmeister's method (this J., 1888, 620) give very low yields of cellulose, and Cross and Bevan's nitric acid method ("Cellulose," p. 97) though extremely simple, cannot be used owing to the fact that the cellulose is profoundly attacked. A summary of the results obtained by the various methods with the same raw materials is contained in the following table:

Materials (all extracted).

Method.	Sulphite wood pulp.	Jute (prepared "half-stuff").	Wood.	Unbleached cotton.
	per cent.	per cent.	per cent.	per cent.
Glycerol-sulphuric acid (König)	74.15	—	—	—
Chlorine gas (Cross and Bevan)	97.9	84.5	60.55	97.85
Concentrated chlorine water	97.65	83.4	57.1	94.7
Dilute chlorine water	98.0	81.1	—	96.8

Sodium hypochlorite	97.4	83.4	50.5	96.8
Phenol (Ger. Pat. 94,467)	90.75	79.4	51.9	94.2

* Product not a pure cellulose.

method for drying cellulose without heat, and the results are concordant. In a strong current of air, dried over phosphorus pentoxide, cellulose may be dried in 4 hours at 90° C., but retains about 0.8 per cent. of moisture in a slower current at 60° C. This method does not give concordant results, since its efficiency is influenced by the quantity of air and the temperature.

—J. F. B.

Paper pulp in French West Africa. P. Ammon. J. Offic. de l'Afrique occid. franç.; Paper Making, 1909, 28, 437.

THE author reports on experiments undertaken on behalf of the French Government with a view to the utilisation

of various fibrous materials of the West African colonies for paper pulp. The first experiments were carried out with sorgho, the dried stalks of which are now burnt on the fields. Attempts to grind these stalks for the preparation of a mechanical pulp having proved fruitless, attention was turned to their treatment by chemical processes. This treatment is most advantageously carried out on the stalks in the fresh condition; they then yield from 45 to 50 per cent. of a pulp superior in quality to the Continental straw pulps. The same process has been applied with success to maize stalks, which are also available in large quantities. Cotton-stalks and aloes are likewise amenable to the treatment. Two indigenous plants, growing in poor sandy soils, belonging respectively to the *Hibiscus* and *Abelmoschus* families have been investigated. The woody portions of the stems yield easily to chemical treatment, and give 50–60 per cent. of a cellulose pulp suitable for ordinary "news" papers or for mixing with esparto for the manufacture of imitation art paper. The bark tissues of *Hibiscus cannabinus* yield 35 per cent. of useful fibres, which may be mixed with esparto for printing papers. Ronier leaves yield fibres of a higher quality than sorgho pulp, but the treatment is not easy and the yield is only 30 per cent. The bark of the baobab tree gives 35 per cent. of excellent fibres, the qualities of which are well known. Lastly, the bark of the Baubinia tree yields a cotton-like fibre, but its treatment is too costly.—J. F. B.

Recovery of volatile liquids by cooling. Claude. See I.

PATENT

Paper; Process for producing translucent —. H. Kuhn, Rochester, N.Y. U.S. Pat. 938,877, Nov. 2, 1909.

PARCHMENT paper, prepared by treating a paper made from cotton with sulphuric acid, is washed, dried, and waxed. The waxed paper is rolled at a high temperature, and a matt surface is then produced on the paper by abrading the same.—W. P. S.

Paper, fabrics, and similar materials; Process for testing [thickness, weight, etc.], whilst in motion. G. C. Chaney. Fr. Pat. 402,225, Apr. 20, 1909.

THE instrument for controlling the weight or thickness of a web of paper or fabric travelling through a machine, is based on the principle that when radiant energy from a constant source (heat or light) passes from a transmitter to a receiver, with the travelling web between them, the variations in the energy transmitted are proportional to the quantities of matter interposed. When heat is employed, the source may be an electric lamp, connected with a constant supply of electricity, and the receiver a simple thermopile connected with a galvanometer. When light is employed, a receiver of selenium or tellurium is applicable. The indications of the instrument are to be referred, in all cases, to those obtained with a standard pattern of the paper or fabric to be controlled. The combination of transmitter and receiver consists of two parallel plates with rollers between them supporting the web of paper or cloth at a uniform distance from each.—J. F. B.

Decorated papers; Process and machine for manufacture of —. F. A. Broekhaus. Fr. Pat. 402,536, May 1, 1909.

THE process for printing and embossing coloured patterns e.g. laeas, etc., on paper, is performed by taking an impression of the article to be reproduced on a celluloid roller, making a galvanic reproduction of the impression and applying the sheet of metal so produced to the surface of a roller, so as to obtain a mould or matrix of the pattern. Another roller, coated with a plastic composition, is revolved in contact with this, and a corresponding pattern is obtained on it in relief. Colour is applied to the surface of the matrix roller, and the web of paper is passed between the two. In this way the pattern is stamped on the paper in uncoloured relief, whilst the main surface of the paper receives the colour. The effect may be varied by spraying colours on the embossed paper at different angles.—J. F. B.

Wood pulp for manufacture of artificial filaments and nitro-cellulose; Process for preparing —. E. Opfermann, E. Friedemann and Act.-Ges. für Maschinenpapierfabrikation. Fr. Pat. 402,462, Apr. 27, 1909. Under Int. Conv., Apr. 15, 1909.

WOOD pulp contains impurities which limit its application in the manufacture of artificial filaments and nitro-cellulose. These impurities are extracted by boiling the cellulose pulp under pressure with a solution of sodium carbonate at a concentration of 0.5–2 per cent., with the addition, if the case seems to demand it, of small proportions of alkali hydroxide or sulphide. Or else the pulp may be boiled with a solution containing 10 grms. of calcium oxide per litre.—J. F. B.

Cellulose; Manufacture of —. R. R. Hollins, London, and T. Taylor, Manchester. Eng. Pat. 23,192, Oct. 30, 1908.

IT is proposed to manufacture pure cellulose, suitable for conversion into artificial silk, gun cotton, collodion, etc., from the waste produced in the process of decorticating sansevieria, sisal, and similar fibrous plants. The waste is preferably treated on the spot, but may be treated away from the plantation if packed in hermetically sealed vessels, or boiled with dilute ammonia and dried, before packing. The coarse fibres and skin are separated from the fine fibres by washing and sifting, and the latter are collected and treated successively with ammonia, a solution of caustic soda and sodium carbonate, and then alternately with bromine and dilute ammonia until the fibres are perfectly white. Any residue of silicious matter is removed from the pure cellulose by treating with dilute hydrochloric and hydrofluoric acids.—F. M.

Cellulose acetate; Process for rendering soft and supple, products [films] manufactured from —. L. Lederer. Fr. Pat. 402,083, Apr. 15, 1909.

As softening agents for films, etc., prepared from cellulose acetate, the esters of phenols and polyphenols or their substitution derivatives are claimed. These agents have the advantage of being insoluble in water and consequently the films retain their elasticity after steeping and washing, e.g., in photographic processes. In particular the addition of 1–2 per cent. of resorcinol diacetate, calculated on the weight of cellulose ester, to the solution of the latter is specified.—J. F. B.

Celluloid; Non-inflammable —. E. F. Clement. Fr. Pat. 402,569, Apr. 29, 1909.

CELLULOID may be rendered non-inflammable by incorporating with it colloidal silica, in a compatible form, in proportions varying with the effect desired. A suitable mixture consists of 90 per cent. of a solution of pyroxilin and 10 per cent. of silica. The silica is best employed in the form of methyl or ethyl silicates, e.g. tetra-ethyl monosilicate, diethyl monosilicate, hexa-ethyl disilicate or diethyl disilicate, these being obtained by the partial hydrolysis of the normal silicic ester.—J. F. B.

Celluloid-like masses; Process for preparing —. C. F. Boehringer und Söhne. Ger. Pat. 214,902, Dec. 5, 1906.

IN making celluloid, the camphor may be entirely or partially replaced by the cyclic ethers obtained by condensing aldehydes or ketones with polyhydric alcohols of the general formula, $\text{CH}_2\text{OH}(\text{CHOH})_x\text{CH}_2\text{OH}$; the following are suitable:—methylene ethylene ether, ethylidene glycol ether, methyleneglycerol, acetonyleglycerol, benzylideneglycerol, erythri-diformal, diacetone-arabitol, and triacetone-mannitol.—T. F. B.

Viscose; Apparatus for manufacture of —. C. C. Leclair. Fr. Pat. 402,804, Sept. 7, 1908.

THIS invention relates to an arrangement by which all the operations in connection with the manufacture of viscose are carried out in a single vessel. For this purpose the pulp, or paper, serving as the raw material, is first torn into small fragments of the size of sawdust. This is charged into the machine, which consists of a large

spherical or elliptical vessel mounted on a hollow trunnion and geared so as to receive both a rotary and oscillating motion. The vessel contains balls to prevent the material from clogging together in a solid mass. It is provided with connections communicating with sources of gaseous pressure and vacuum, also with orifices for the introduction of reagents or water in the form of a spray, and is surrounded by a jacket for the circulation of a heating or cooling medium.—J. F. B.

Paper and fibrous materials; Process for the treatment of waste — in the preparation of paper pulp. L. Herz. Nürnberg, Germany. Eng. Pat. 24,131, Nov. 10, 1908.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENTIAL OILS, & EXTRACTS.

Quinine sulphate; Tests for the purity of —. F. Tatin. Pharm. Soc., Nov. 9, 1909. Pharm. J., 1909, 83, 600—604.

Nux vomica seeds; Alkaloidal standard for, and method of determination of alkaloids in — [in the German Pharmacopœia]. G. Weigel. Pharm. Zentralh., 1909, 50, 783—784.

THE minimum standard of 2.5 per cent. of total alkaloids, prescribed by the Ph. G. IV., is not attained by the undried commercial drug. By the Keller-Fromme method of determination, the percentage of alkaloids ranges from 2.1 to 2.25. Since *Nux vomica* seeds lose, as a rule, about 10 per cent. of moisture on drying, the dried drug would pass the official standard by this method. The method of determination given in the Ph. G. IV., is, moreover, incorrect, affording too high results, since a portion of the soap formed by the action of the alkali on the fat present in the seeds is weighed as alkaloid. It is suggested, therefore, that the Keller-Fromme method should be made official; and that the minimum content of alkaloids for the natural drug should be 2 per cent., the figure correctly given in the French Codex, 1908.

—J. O. B.

Quino-quino balsam from Myroxylon balsamum var. J. punctatum. C. Hartwich and A. Jama. Schweiz. Woeh. Chem. Pharm., 1909, 47, 625—630, 641—647.

Tolu balsam, Peru balsam, and Quino-quino balsam are all yielded by the same tree, but by distinct botanical varieties thereof. *Myroxylon balsamum* (L.) var. *a. genuinum* (Baill.) is the source of Tolu balsam. The variety *β. perierae* (Baill.) gives Peru balsam. The variety *J. punctatum* (Baill.) yields quino-quino balsam. The chemical differences of these closely allied products are thus tabulated:—

Myroxylon balsamum.

	Var. <i>A. genuinum</i> . Tolu balsam.	Var. <i>B. pereiræ</i> . Peru balsam.	Var. <i>J. punctatum</i> . Quino-quino balsam.
Acid value	114—158	68—80	8.03
Saponification value	155—187	over 245	134.09
Ester value	up to 73	at least 165	53.79
Cinnamein	7.5 per cent.	62—64 per cent.	5.83 per cent.
Benzyl benzoate in cinnamein	present in quantity	almost wholly	almost exclusively
Benzyl cinnamate in cinnamein	in small amount	in very small amount	only traces
Vanillin	0.05 per cent.	0.046—0.05 per cent.	0.044 per cent.
Free benzoic acid	only a small amount	none	the greater part
Free cinnamic acid	the greater part	exclusively	in minute quantity
Resin	80 per cent.	30 per cent.	78.5 per cent.
Free resin alcohol	none	none	at least 5.7 per cent.
Resinotannol	Tolu-resinotannol, $C_{17}H_{18}O_5$	Peru-resinotannol, $C_{18}H_{20}O_5$	Tolu-resinotannol, $C_{17}H_{18}O_5$
Benzoic acid in resin	small amount	very small amount	all
Cinnamic acid in resin	in predominant quantity	in predominant quantity	none

THE ammonia test as described in the French Pharmacopœia has been found to be more satisfactory than those described in other Pharmacopœias. The minimum amount of 10 per cent. ammonia which will yield a clear solution at 15° C. with 5 c.c. of a solution of pure quinine sulphate saturated at 15° C., is 4.4 c.c. The saturated solution is prepared by dissolving the salt in 30 c.c. of boiling water, cooling to 15° C. with shaking, then leaving at this temperature for 30 minutes with stirring. The requirements of the German, French and Dutch Pharmacopœias are either impossible of fulfilment or unnecessarily stringent. The author considers a minimum of 6.0 c.c. of ammonia to be reasonable. Variations in the basicity of quinine sulphate affect the amount of ammonia required. Salts which are basic appear less pure than is actually the case. Inorganic salts exercise a considerable influence on this test; in fact, the ammonia test can only be used with satisfactory results on quinine sulphate, and not on the other salts. The present B. P. test for cinchonine and cinchonidine is to be preferred to the ammonia test, as the former can be applied to any salt. This test is more delicate if “Æther Purificatus” be used in place of “Æther.” The ammonia test is the only means of detecting hydroquinine, apart from actually isolating this alkaloid, the presence of which, however, may be no drawback.—F. SHDN.

The quino-quino balsam examined was in reddish-brown irregular pieces, with a pleasant aromatic odour when warmed, like that of Tolu balsam. When melted and examined with the microscope when cold, it shows numerous crystals.—J. O. B.

Mace, Papuan; Detection of — [in Banda mace]. C. Griebel. Z. Untersuch. Nahr. Genussm., 1909, 18, 202.

THE arillus of *Myristica argentea*, a native of New Guinea, is met with in commerce under the names of Papuan or Macassar mace. It is less powerfully fragrant, and has a somewhat different aroma from that of true mace from *Myristica fragrans*, and it fetches a markedly lower price. The whole mace of *M. argentea* is readily distinguishable from that of *M. fragrans*, since the arillus is divided into four large bands only, which are entire, except at the upper portion, and are re-united at the apex. The colour is brighter, especially after powdering. The odour of powdered Papuan mace is peculiar, somewhat resembling that of saffras, possibly owing to the presence of safrol in the essential oil. The admixture of powdered Papuan with Banda mace cannot be detected microscopically. To detect the substitution or admixture, 0.1 gm. of the powder is extracted by agitation for one minute with 10 c.c. of light petroleum spirit, and filtered. Simultaneously, the same amount of genuine Banda mace

powder is similarly treated, as a control. About 2 c.c. of each filtrate are then mixed with an equal volume of acetic acid, and strong sulphuric acid is added to each, avoiding admixture. The extract of Banda mace will show a yellow ring of colour at the zone of contact; in the presence of Papuan mace, a reddish tint will be developed, more or less rapidly, the depth of the colour being proportional to the amount of adulterant present. If no such colour appears after 1 to 2 minutes, the absence of false mace may be assumed. Genuine mace begins to show a reddish tint after that time. More definite confirmation may be obtained by isolating the resinous constituents which give rise to this colour-reaction. The petroleum ether extracts are evaporated, and the essential oil is driven off. The residues are taken up with ether; free acids are removed by shaking the ether solution first with sodium carbonate solution, then six or eight times with 1 per cent. sodium hydroxide solution, until the alkaline liquid is no longer coloured on adding excess of sulphuric acid. The mixed alkaline extracts are acidified, and again shaken with ether. On evaporating the ether extracts, the residue of true mace gives at first a brown, and then a brownish-red colour with sulphuric acid. The residue from Papuan mace is immediately coloured bright raspberry red, passing to magenta.—J. O. B.

Camphor; Chinese —. Chem. and Drug. Nov. 27, 1909. [T.R.]

IN 1907 23,231 cwts., valued at £271,433, was exported from Foochow, while in 1908 the figures fell to 9,644 cwts., valued at £69,302. The average value per cwt., which rose from £11 15s. in 1906 to £13 15s. in 1907, fell in 1908 to £7 3s. 9d. The falling market is attributed to the speculation in 1907, when prices rose abnormally high. The inevitable collapse followed, partly due to the fact that it was feared synthetic camphor could be manufactured at lower prices than natural, but principally because the home markets were overstocked, the supplies at Foochow excessive, and speculators at both ends in a hurry to get rid of their stocks because of the declining rates. In addition to this, Formosa camphor was being sold at continually lower prices. Camphor oil was exported in 1908 to the amount of 99 cwts. (£119), against 10,345 cwts. (£20,805) in 1907.

Otto of rose, 1909. J. C. Umney. Chem. and Drugg., 1909, 75, 786.

THE characters of samples of different brands of otto of rose of the present season, are shown in the following table:—

Sp. gr. at 30°/15° C.	Refractive index at 25° C.	M. pt. ° C.	Alcohols, as C ₁₀ H ₁₈ O, per cent.	Odour.
0.861	1.4622	21—22	76.1	Very soft and lasting
0.860	1.4635	21—22	73.3	Very sweet
0.858	1.4630	21	74.1	" "
0.860	1.4620	21—22	73.7	Fine "
0.856	1.4620	21—22	72.5	Not very lasting
0.860	1.4640	21—22	75.1	Fair
0.857	1.4612	21	75.5	Strong and coarse
0.860	1.4630	21—22	78.2	Impure
0.862	1.4640	21	78.4	

NOTE.—The otto was placed on blotting paper, and the odour tried immediately, after one hour, and after 24 hours.

For the purposes of comparison the characters of otto of rose of the 1896 season, are given:—

Sp. gr. at 30°/15° C.	Crystallising point, ° C.	Alcohols, as C ₁₀ H ₁₈ O, per cent.	Quality.
0.8556	20.9	70.1	Fine
0.8599	20.4	72.3	
0.861	20.4	73.1	
0.859	20.6	72.3	
0.856	21.7	69.2	
0.863	19.4	75.6	Impure
0.868	18.7	77.6	
0.868	18.9	76.6	

It will be noticed that the percentage of alcohols in line otto of rose has risen appreciably since 1896. The fact that impure specimens of otto of rose agree more closely in specific gravity and congealing point with pure otto of rose than was the case in 1896, is probably due to the use, as adulterant, of otto of rose steoptene, large quantities of which are now produced in the manufacture of oil free from steoptene. The author concludes from his results that adulteration is now carried out much more skillfully than ten years ago; and that any samples which show characters much outside fairly well-defined limits may be at once condemned as impure. Samples with characters only slightly outside the limits of the season's otto should not be condemned if the odour is of the finest quality. The purity of a sample of otto of rose cannot be judged from the physical and chemical characters alone; the odour must also be taken into consideration.—A. S.

Oil of cloves; Composition of —. Aldehydic and ethereal constituents. H. Masson. Comptes rend., 1909, 149, 795–797.

FROM the portion of the oil boiling at 65°–90° C. under 15 mm. pressure, the author has isolated, by means of sodium bisulphite, α -methylfurfuraldehyde, and from the fraction boiling at 105°–120° C. under 15 mm. pressure, a dimethylfurfuraldehyde the constitution of which was not ascertained. The latter fraction contained also methyl salicylate.—J. C. C.

Essential oils. H. Haensel. Chem. Zentr., 1909, 2, 1556–1557.

Birch bud oil. A sample examined had the sp. gr. 0.9748 at 20° C., $[a]_D = -5.73^\circ$. It contained 47.1 per cent. of betulol in the free state and 29.6 per cent. in the form of esters (betulyl acetate and probably formate).

Ficaria oil. By steam-distillation of the plant, *Ranunculus ficaria*, L., there was obtained a dark-brown oil permeated with solid matter, and having a tobacco-like odour. The oil had the sp. gr. 0.9101 at 24° C. after filtration. It distilled between 150° and 310° C. It contained palmitic acid and reduced ammoniacal silver solution.

Macassar sandalwood oil. Sp. gr. 0.9723 at 18° C., $[a]_D = -16.92^\circ$; soluble in 2 parts or more of 70 per cent. alcohol; saponification value, 7.7; santalol content, 96 per cent.

New Caledonia sandalwood oil. Sp. gr. 0.9665 at 20° C., $[a]_D = -21.69^\circ$; soluble in two parts or more of 70 per cent. alcohol; saponification value, 6.1; santalol content, 95.5 per cent. The oil was yellow in colour and could not be distinguished from East Indian oil with regard to odour.

Asparagus root oil. 0.0108 per cent. of a dark brown oil with an intense sourish smell was obtained from dry asparagus roots. It contained palmitic acid, and had the sp. gr. 0.8777 at 23° C., acid value, 33; ester value, 68.

Spikenard (Valeriana celtica) oil was obtained with a yield of 0.1 per cent. It was a thick yellow oil with an odour resembling that of valerian and hazelwort oils. Sp. gr. 0.9693 at 20° C., $[a]_D = -42^\circ$, saponification value 62.5, ester value of oil after saponification and acetylation, 71.9. It was miscible in all proportions with 90 per cent. alcohol, and contained palmitic acid and a sesquiterpene with b.pt. about 255° C., sp. gr. 0.9359 at 20° C., and $[a]_D = -30.88^\circ$.—A. S.

Rhus Cotinus or Young Fustic; Essential oil of —. G. Perrier and A. Fouchet. Bull. Soc. Chim., 1909, 5, 1074–1075.

THE leaves and twigs of *Rhus Cotinus* or "Young Fustic" were subjected to steam-distillation, and the distillate extracted with ether. The ethereal solution when dried and distilled, left an oil, amounting to about 0.1 per cent. This oil is colourless and has a smell resembling that of turpentine. It has the sp. gr. 0.875 at 15° C., a refractive index of 1.4693, and $n_D = +13^\circ$ at 18° C.; it dissolves in all proportions in 94 per cent. alcohol. The solubility in 90 per cent. alcohol is 33, in 85 per cent. alcohol 10, and in 80 per cent. alcohol 6 per cent. The oil becomes resinified and yellow on exposure to the air. 1 gm. of the oil neutralises 6.1 mgrms. of potassium hydroxide, and when hydro-

lysed the same weight of the oil requires 34.3 mgrms. The free primary alcohols in 1 grm. of the oil correspond to 79 mgrms. of phthalic acid. F. SHDN.

Carvenene and "terpinene." Essential oils; Constituents of — F. W. Semmler. Ber., 1909, 42, 4171–4174.

THE author has made further experiments with carvenene obtained from carvenone (this J., 1909, 106). When oxidised with alkaline permanganate at the ordinary temperature, carvenene yields α,α' -dihydroxy- α -methyl- α -isopropyladipic acid, m.pt. 189° C., which can readily be converted into the dilactone, m.pt. 72°–73° C. Carvenene must be, therefore, $\Delta^1,3$ -dihydrocymene, which Wallach has described as α -terpinene (this J., 1909, 959). The author considers that carvenene prepared as above is practically pure.—F. SHDN.

Adrenaline; Iodic acid reaction of — L. Kranss. Biochem. Zeits., 1909, 22, 131.

FRAENKEL and Allers have recently described (this J., 1909, 671) a reaction of adrenaline [adrenine] with iodic acid which had already been described by the author (*loc. cit.*, 1908, 1039). With the author's mode of procedure, the liberation of free iodine can be detected. Fraenkel and Allers, on the other hand, did not detect iodine at any stage of the reaction. The author finds, however, that the iodine may be detected in the following way:—A few drops of iodic acid solution (1:20) are mixed with a few drops of adrenaline solution (1:1000); on adding a few drops of starch solution, the characteristic blue colour appears.—Fraenkel and Allers mode of effecting the reaction is, however, more sensitive than that described by the author.—L. E.

Resorcinol; Characteristic reaction of — with copper sulphate and potassium cyanide solutions. Volcy-Boucher and J. Girard. Répertoire Pharm., 1909, 21, 433–434.

A FEW c.c. of the liquid to be tested are treated with a few drops of 10 per cent. solution of copper sulphate, followed by an equal volume of 10 per cent. potassium cyanide solution. On shaking, a reddish colour is developed; the mixture is then diluted with water to a reddish-yellow tint. When observed by reflected light it will show a very marked green fluorescence in the presence of resorcinol. This fluorescence is quite distinct with a dilution of 1 in 10,000.—J. O. B.

Aldehydes; New general methods of synthesising aromatic — A. Guyot. Comptes rend., 1909, 149, 788–790.

$\alpha\beta$ -Diketonic esters condense with phenols or tertiary amines to form acylphenylglycollic esters:

which when heated with sulphuric acid furnish aldehydes. As, however, the aldehydes produced are attacked by sulphuric acid, it is better first to boil the esters with an aqueous solution of a copper salt and to boil the resulting phenylglyoxylic acids with dimethyl-*p*-toluidine:

The same aldehydes can also be obtained by heating the acylphenylglycollic esters with aqueous potassium hydroxide and oxidising the resulting phenylglycollic acids with alkaline potassium ferricyanide. The mesoxalic esters, $CO_2R.CO.CO_2R$, can replace the diketonic esters in the above reactions.—J. C. C.

Xeroform (bismuth-tribromophenol); Determination of bismuth in — O. Schlenk. Pharm.-Zeit., 1909, 54, 538.

FROM 1 to 2 grms. of the compound are boiled with about 20 c.c. of 10 per cent. sodium hydroxide solution, with constant stirring, until the bismuth is entirely converted into oxide. The precipitate is then washed, on a filter, with hot dilute sodium hydroxide solution, until the filtrate contains no more tribromophenol. The precipitate is then washed with hot water, transferred to a crucible, and incinerated. The residue is moistened with dilute nitric

acid, and again gently incinerated. Treated in this manner xeroform should yield about 50 per cent. of bismuth oxide.—J. O. B.

Fat and wax of tubercle bacilli. Fontes. See XII.

Recovery of tartaric acid from residues of wine manufacture. Janson. See XVII.

PATENTS.

Substances for conferring on human beings and other animals immunity against disease; Production of — Kalle and Co., Akt.-Ges., Biebrich-on-Rhine, Germany. Eng. Pat. 1431, Jan. 20, 1909. Under Int. Conv., March 24, 1908.

IMMUNITY against a disease may be conferred upon a human being or an animal by injecting into the blood, disintegrated immune blood or organism cells, obtained from another human being or animal which has passed through the disease in question. The disintegration can be carried out by pouring the blood into a solution of common salt and utilising the clear liquid which separates. The mass which settles to the bottom of this liquid can be removed, ground in a mortar, and filtered. The filtrate contains immunity-conferring bodies. The disintegration can also be effected by physiological or mechanical means.—F. SHDN.

Pharmaceutical compounds [from chaulmoogra oil]; Preparation of new — P. A. Newton, London. From Farbenfabr. vorm. F. Bayer and Co., Elberfeld, Germany. Eng. Pat. 1984, Jan. 27, 1909.

CHAULMOOGRA oil, obtained from the seeds of *Taraktogenos kurzii*, is hydrolysed, and purified by means of hot water or steam. The mixture of acids thus obtained is esterified and purified by distillation in a vacuum. The oil so obtained can be used for medicinal purposes.—F. SHDN.

Salve and ointment; Non-odorous phenol — N. Sulzberger, New York. U.S. Pat. 938,614, Nov. 2, 1909.

AN ester of a monohydric phenol with a fatty acid which has more than twelve carbon atoms, the melting point of which is above 40° C., is mixed with a sufficient quantity of an unguent to reduce its melting point to about body temperature. Phenyl stearate of m. pt. 52° C. may be used as the basis of the ointments, which are stated to be odourless and non-irritant.—T. F. B.

p-Aminophenylarsinic acid; New mercury salt of — J. Altschul, Assignor to Act.-Ges. f. Anilinfabr., Berlin. U.S. Pat. 938,939, Nov. 2, 1909.

A MERCURY salt of *p*-aminophenylarsinic acid, of the composition, $NH_2.C_6H_4.AsO_4.H_2Hg$, is obtained by the action of an alkali salt of the acid on a mercury salt in presence of excess of alkali; it is soluble with difficulty in water, insoluble in alcohol and ether, and is decomposed by caustic soda solution, with formation of yellow mercuric oxide. It contains about 46 per cent. of mercury and 17 per cent. of arsenic. (Compare Eng. Pat. 8959 of 1908 and U.S. Pat. 914,408 of 1909; this J., 1909, 442.)—T. F. B.

Phenol halogen phthalein compound. W. R. Orndorff, Ithaca, N.Y., Assignor to Parke, Davis, and Co., Detroit, Mich. U.S. Pat. 939,075, Nov. 2, 1909.

HALOGENATED phenolphthaleins are obtained by heating phenols with halogenated phthalic acids in presence of dehydrating agents until solidification of the mixture takes place. The phthalein thus obtained from phenol and tetrachlorophthalic acid melts at about 316° C., is colourless, tasteless, and odourless; soluble in methyl and ethyl alcohols, acetone, ether, and acetic acid, and insoluble in water and petroleum spirit; it is also soluble in solutions of alkali hydroxides and carbonates, and is reprecipitated from these solutions by acids.—T. F. B.

Carbon chlorides; Process of utilising — H. Pichon and T. Truchelut. Fr. Pat. 402,235, April 20, 1909.

THE use of carbon tetrachloride and other chlorides of carbon has been restricted in many industries by their tendency to decompose, with the liberation of hydrochloric

acid, particularly when mixed with light petroleum. According to the present invention this tendency is entirely suppressed by adding to the carbon chloride from 1 to 5 per cent. of oil of turpentine or other hydrocarbon with a great affinity for oxygen.—J. F. B.

Tribromocatechol; Process for preparing —. Chem. Fabr. von Heyden A.-G. Ger. Pat. 215,337, July 19, 1908.

WHEN catechol is treated with three mols. of bromine, in presence of solvents other than acetic acid, tribromocatechol of m. pt. 138°–139° C. is obtained: it crystallises with 1 mol. of water. It is readily soluble in alcohol, ether, and acetone, but sparingly soluble in water, chloroform, and petroleum spirit. On methylation it is converted into tribromoveratrol, of m. pt. 85°–86° C. It possesses antiseptic properties. (On bromination in presence of acetic acid, catechol is converted into di- and tetra-bromo derivatives.)—T. F. B.

Alkyl ethers of phenols and other aromatic hydroxylic derivatives; Manufacture of —. A. Gerber, Bonn on Rhine, Germany. Eng. Pat. 17,834, July 31, 1909. Under Int. Conv., July 31, 1908.

SEE Ger. Pat. 214,783 of 1908; this J., 1909, 1223.—T. F. B.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Burnt manuscripts rendered legible by photography. Reiss. Pharm. Zentralh., 1909, 50, 739.

THE burnt paper is carefully placed on a glass plate, and cautiously brushed over with varnish. Another sheet of glass is then superimposed and the whole is fastened in a printing frame. A photograph is taken of the burnt paper, using an orthochromatic plate and suitable colour screens if vegetable ink has been employed; in the case of inks with an iron base, or one of aniline colours, the negative may be taken in the ordinary way. In the case of pencil marks, the objective must be inclined on its axis, so that light reflected from the graphite marks may traverse it. The writing may sometimes thus be deciphered even on manuscripts which have been torn in pieces before being burnt.—J. O. B.

Detecting traces of chlorides in gelatin. Lüppe-Cramer. See XIV.

PATENTS.

Toning green by means of vanadium; Solid preparation for — and method of preparing it. Chem. Fabr. auf Actien vorm. E. Schering. Ger. Pat. 215,071, Jan. 16, 1909.

WHEN liquid vanadium chloride (500 grms.) is mixed with anhydrous oxalic acid (1310 grms.), a solid product is produced, which is readily soluble in water, and which can be compressed into tablets suitable for use in toning silver bromide prints green. A toning bath may be prepared by dissolving 3.8 grms. of the above product, 1.5 grms. of anhydrous oxalic acid, 1 gm. of ferrie oxalate, and 1 gm. of potassium ferriocyanide in 1 litre of water; in this solution the prints will be toned in from 3 to 5 minutes.—T. F. B.

Rendering soft and supple, products [films] from cellulose acetate. Fr. Pat. 402,083. See XIX.

XXII.—EXPLOSIVES, MATCHES, &c.

Explosives in the United States; Permissible —. J. A. Holmes. Mining World, Nov. 20, 1909.

THE following is a list of permissible explosives tested by the United States Geological Survey at Pittsburg, Pa.

Subject to the provisions named below, a permissible explosive is defined as an explosive which is in such condition that the chemical and physical tests do not show any unfavourable results; which has passed gas and dust gallery tests Nos. 1 and 3, as described in circular No. 1 (U.S. Geol. Survey, Explosives circular); and of which, in test No. 4, $1\frac{1}{2}$ lb. (680 grms.) has been fired into the mixture there described without causing ignition.

Aetna coal powder A.A. B. and C, Aetna Powder Co. Bituminite No. 1, Jefferson Powder Co. Black Diamond Nos. 3 and 4, Illinois Powder Manufacturing Co. Carbonite Nos. 1, 2, 3, 1-L.F., and 2-L.F., E. I. Du Pont de Nemours Powder Co. Coalite Nos. 1 and 2D, Potts Powder Co. Coal Special Nos. 1 and 2, Keystone Powder Co. Collier dynamite Nos. 2, 4, and 5, Sinamahoning Powder Mfg. Co. Giant A, B, and C low-flame dynamite, Giant Powder Co. Masurite M.L.F., Masurite Explosive Co. Meteor dynamite, E. I. Du Pont de Nemours Powder Co. Mine-ite A and B, Burton Powder Co. Monobel, E. I. Du Pont de Nemours Powder Co. Tunnelite Nos. 5, 6, 7, and 8, G. R. McAbee Powder and Oil Co.

Provided: (1) That the explosive is in all respects similar to sample submitted by the manufacturer for test. (2) That No. 6 detonators, preferably No. 6 electric detonators (double strength), are used of not less strength than 1 gm. charge, consisting by weight of 90 parts of mercury fulminate and 10 parts of potassium chlorate (or its equivalent), except for the explosive "Masurite M. L. F.," for which the detonator shall be of not less strength than $1\frac{1}{2}$ grms. charge. (3) That the explosive, if frozen, shall be thoroughly thawed in a safe and suitable manner before use. (4) That the amount used in practice does not exceed $1\frac{1}{2}$ lb. (680 grms.), properly tamped.

The above partial list includes all the permissible explosives that have passed these tests prior to Oct. 1, 1909.

Recovery of volatile liquids by cooling. Claude. See I.

PATENTS.

Pyroxylin; Process for preparing raw materials for the manufacture of —. E. Nowicki. Fr. Pat. 402,197, Apr. 19, 1909.

FLAX, hemp and ramie, or their wastes, are claimed as raw materials for nitration in the manufacture of pyroxylin, the fibres being bleached and purified and submitted to a mechanical preparation to bring them into a suitable state for the process. It is stated that since these fibres are devoid of cuticle, and when mechanically prepared, their central canals are open at both ends, they are far more amenable to the uniform action of the acid than cotton fibres. Moreover, the finished product may be compressed to a greater density than nitrated cotton. If desired, these fibres may be mixed with cotton or other cellulose fibres before nitration.—J. F. B.

Manufacture of cellulose. Eng. Pat. 23,192. See XX.

Preparing wood pulp for manufacture of artificial filaments and nitrocellulose. Fr. Pat. 402,462. See XIX.

XXIII.—ANALYTICAL CHEMISTRY.

APPARATUS.

Volatile acids in wines and vinegars; Apparatus for use in the determination of —. H. C. Gore. U.S. Departmt. of Agric. Aug. 18, 1909. Bureau Chem., Circular No. 44.

IN this modification of the Hortvet-Sellier apparatus, a copper flask is substituted for the outer glass flask and a constant feed device for the flask has been added; there are also two changes of a minor nature consisting in a small ridge blown in the inner flask to form a shoulder for the rubber gasket and the elimination, as unnecessary, of the dropping funnel. The constant water feed is operated by running the supply water through tube, A

(see fig.), which passes through tube, *b*. The overflow passes through *b*, and rises through tube, *c*, to the small basin, *d*, which is connected with the drain. Tube, *a*, is placed within tube, *b*, because steam is so prevented from passing out through *b*. Distilled water should be used which has been largely freed from carbon dioxide by passing a rapid stream of air through it for 20–30 minutes. The water should be admitted somewhat more rapidly than it is used. The rate of flow is conveniently regulated by comparing the rate of drip in the small sight tube, *e*, with that from the condenser. Experiments with the apparatus showed that when tap water was supplied to the generator there was an error due to the presence of carbon dioxide in the distillate, equal to about 0.3 c.c. of *N*/10 alkali in 100 c.c., phenolphthalein being used as indicator. When ordinary distilled water was used, the error was about 0.15 c.c. When distilled water was employed from which the greater portion of carbon

of the outer flask being open. All connections are made tight and tube, *f*, closed. In the case of wines, about 100 c.c. of the distillate are collected. In the case of vinegars, from 200 to 300 c.c. are required. The distillate is titrated with standard alkali free from carbonates, using phenolphthalein as indicator, and 0.05 c.c. is subtracted from the number of c.c. of alkali used, for each 100 c.c. of distillate. About fifteen minutes are required for a determination of volatile acid in wine and from thirty to forty-five minutes in the case of vinegar. The volume of liquid in the inner flask increases but very slowly during a determination.

PATENT.

Pyrometer. J. L. Zander, Newark, N.J. U.S. Pat. 938,934, Oct. 26, 1909.

THE claim is for a mechanical pyrometer comprising a casing provided with a dial and an index. The latter is actuated by the expansion of two rods of different materials, which are linked together, and are situated inside an expansion tube, which is fixed to the casing. The extremity of the one expansion rod is fixed to the free end of the expansion tube and the free end of the other expansion rod is connected by means of a "spring-controlled arbour" with a pinion and crank, the latter actuating the dial with the interposition of a suitable gearing arrangement. This comprises an arm, upon which is a toothed sector which engages with the pinion, a stem connected with the crank, a link connected with the stem, and a tubular element connected with the link.—O. R.

INORGANIC—QUALITATIVE.

Metals of the second group: New method for the qualitative detection of — without using sulphurated hydrogen and ammonium sulphide. E. Selvaen, Bull. Assoc. Chim. Suér. et Dist., 1909, 27, 361–367.

THE acid filtrate from the metals of the first group is treated with thioacetic acid, heated just to boiling, cooled and filtered. After washing, the mixture of sulphides is heated with concentrated nitric acid, the solution thus obtained, and the residual precipitate being treated as follows:—

The filtrate (arsenic, lead, bismuth, copper, cadmium) after expulsion of excess of nitric acid, is treated with excess of sodium hydroxide.

Precipitate (copper, bismuth, cadmium) is dissolved in nitric acid, the solution being precipitated with ammonia.

Filtrate (arsenic, lead) is treated with dilute sulphuric acid.

Precipitate, Bismuth.

Filtrate (copper, cadmium) is acidified with hydrochloric acid and treated with potassium thiocyanate.

Precipitate, Lead.

Filtrate, Arsenic.

Precipitate, Copper.

Filtrate, Cadmium.

The precipitate (tin, antimony, mercury, and some lead) is treated with alkaline ammonium tartrate which dissolves the lead sulphate. The residue is dissolved in *aqua regia*; after expelling excess of acid, the solution is treated with hydrazine hydrochloride or sulphate.

Precipitate, Mercury.

Filtrate, Tin, antimony.

—L. E.

dioxide had been removed by aeration, the error was but 0.05 c.c. The error is constant and may be subtracted from each determination. The apparatus is operated as follows: Place 10 c.c. of the sample in the inner flask, which should have been removed from the outer flask and should be quite cool. If the sample is noticeably charged with carbon dioxide, a current of air should be passed through it for a few minutes by attaching to the flask a stopper bearing a glass tube which is connected with suction. The air passes in through the side tube in the flask and washes out practically all the carbon dioxide in the sample, without removing appreciable quantities of volatile acid. Connect the flask with the distilling bulb and place in the outer flask, tube, *f*,

Arsenious acid: Detection of — in presence of arsenic acid, by means of electrolysis. E. Covelli, Chem.-Zeit., 1909, 33, 1209.

IN alkaline solution, arsenites, when submitted to electrolysis, evolve arsine at the cathode, whilst arseniates do not. To detect arsenites in presence of arseniates, 30 c.c. of the solution made alkaline by potassium hydroxide, are electrolysed in a U-tube, in the upper part of the cathode limb of which, a piece of paper impregnated with silver nitrate solution is suspended. In a very few minutes (10 minutes, if 0.01 mgrm. of arsenic trioxide be present) the paper is coloured deep brown if any arsenite be present.—J. T. D.

INORGANIC—QUANTITATIVE.

Lead; Volumetric determination of — with potassium permanganate. H. Bollenbach. *Chem.-Zeit.*, 1909, **33**, 1142—1143.

THE method depends upon the oxidation of an alkaline lead solution with permanganate. The course of the reaction has not been satisfactorily determined, but numerous experiments have shown that concordant and accurate results can be obtained. The permanganate is standardised with lead nitrate, 20 c.c. of a solution of permanganate containing about 3 grms. per litre being mixed in a 400—500 c.c. flask with 300—400 c.c. of hot distilled water, about 5 c.c. of $N/2$ sodium hydroxide solution, and 2—5 grms. of potassium nitrate (to accelerate the settling of the precipitate produced subsequently). A solution of lead nitrate of known lead-content is now run in from a burette, the mixture being shaken vigorously and allowed to settle after each addition, until the pink colour disappears. The actual determination is carried out in a similar manner, the alkaline lead solution being treated with excess of permanganate, and the excess titrated with the lead nitrate solution. A. S.

ORGANIC—QUANTITATIVE.

Total nitrogen determination by the Kober method. F. W. Gill and H. S. Grindley. *J. Amer. Chem. Soc.*, 1909, **31**, 1249—1252.

ON determining the total nitrogen of several organic substances by the Kober aeration method, it was found that in the cases of cottonseed meal, wheat bran, rice bran, and linseed oil meal, the result was lower than the figure obtained by the official distillation procedure. These four substances contain respectively, in the order named, 6.9, 6.6, 6.4, and 5.9 per cent. of magnesium,

and 15.0, 13.5, 11.4 and 8.1 per cent. of phosphorus; whereas the average content of seventeen other vegetable substances is 1.6 per cent. of magnesium and 2.74 per cent. of phosphorus. The authors conclude that in the cases named, magnesium ammonium phosphate is formed, thereby preventing the removal of the nitrogen. The difficulty can be overcome by keeping the aerating solutions in the Kjeldahl flasks warm during the entire period of aeration. The Kober aeration procedure has the advantage over the official method in that it requires no attention when once started and no heat is used for distillation, save in the cases above specified. The Kober method is carried out in the following manner. After the usual digestion of the organic material in the Kjeldahl flasks with 25 c.c. of concentrated pure sulphuric acid, mercury, and potassium sulphate, the liquids are cooled, and from 90 to 95 c.c. of distilled water free from ammonia are then added to each of the flasks. After cooling to room temperature, the flasks are connected to 16-ounce bottles, each of which contains a measured excess of standard sulphuric acid plus 130 c.c. of water for absorption of the ammonia. The Kjeldahl flasks are also connected to vessels, from which is drawn through a widened tube, by the air current, the necessary amount of caustic soda-sodium sulphide solution. After the alkaline solution has been drawn into the flasks, wash-bottles containing the dilute sulphuric acid for rendering the air for aeration free from ammonia, are attached in place of the vessels which contained the caustic alkali solution. The rapid, but not violent, aeration of the solutions in the Kjeldahl flasks is continued for at least one and a half hours. — H. H. S.

XXIV.—SCIENTIFIC & TECHNICAL NOTES.

Acetylene; Action of metallic magnesium on —. J. Novák. *Ber.*, 1909, **42**, 4209—4213.

THE product obtained by heating metallic magnesium in acetylene gas consists of a mixture of bodies the nature of which is not yet definitely determined. On treating the reaction-product with water, acetylene and allylene gases are evolved and may be separated by their varying behaviour towards an ammoniacal solution of cuprous chloride containing excess of ammonium chloride; copper acetylide is insoluble in the reagent, whereas copper allylenide is soluble. The reaction may be advantageously used for the preparation of allylene. Other hydrocarbons and also alcohols and wood charcoal when heated with magnesium yield similar products.—J. L. H.

Tobacco fermentation. F. W. J. Boekhout and J. J. Ott de Vries. *Zentralbl. f. Bakter. u. Parasitenk.*, 1909, II. Abt., 24, 496—511. *Chem. Zentr.*, 1909, 2, 1583.

TOBACCO leaves are oxidised by oxygen at 33° C., and more rapidly at 100° C., oxygen being combined and carbon dioxide liberated. The action is greater in presence of water. Besides carbon dioxide, other volatile compounds are produced; the quantity of non-nitrogenous extractive matter, including pentosans, is reduced, and furfural is formed. According to the authors the "fermentation" of tobacco is a chemical process due to the action of the oxygen of the air, the iron present in the plant probably acting as a catalyst. Dutch tobacco contains 6—9 mgrms. of ferric oxide per 10 grms. of leaves. —A. S.

Patents Act, 1907; Decisions under the —. Times, Nov. 27 and 30, 1909.

THE Comptroller-General of Patents has refused to revoke a patent of 1900, at present owned by De Dion Bouton (Limited), relating to improvements in valve-operating mechanism. Revocation was applied for on the ground that the patented article is manufactured mainly or exclusively outside the United Kingdom. It was admitted by the applicants that the patent was of little or no value, but it was alleged that the patentees had abused their monopoly rights. The Comptroller, however, came reluctantly to the conclusion that he was unable on that ground to revoke the patent. He gave the patentees 15 guineas costs.

The Comptroller has also refused to revoke letters patent of 1904 for a method and apparatus for cutting plates and other metal articles by means of a blow-pipe or burner. Revocation was applied for on the ground that the manufacture of the patented article was carried on mainly or exclusively abroad; but the owners of the patent, the British Oxygen Company, alleged that at the date of the hearing there was a substantial manufacture in this country.

there are concise descriptive paragraphs of introductory character, with descriptions of analytical methods. The subdivisions are the following:—(1) Water. (2) Assaying. (3) Fends. (4) Sulphuric acid. (5) Alkali. (6) Bleaching powder. (7) Nitre and explosives. (8) Ceramics. (9) Glass. (10) Mortar and cement. (11) Illuminants. (12) Starch and sugar. (13) Fermentation industries. (14) Fats and oils. (15) Essential oils and perfumery. (16) Tanning agents. (17) Textile fibres and paper. (18) Photography. (19) Dyestuffs and colours. (20) Physiological chemical analysis. IV. Appendix. Various recipes, etc. The subject matter fills 580 pages.

THE PREVENTION OF INDUSTRIAL ACCIDENTS. No. 1. General Pamphlet. Prepared by FRANK E. LAW, M.E., and WILLIAM NEWELL, A.B., M.E., of the Staff of the Fidelity and Casualty Company of New York. Published by the Fidelity and Casualty Company of New York, 92 to 94, Liberty Street, and 97 to 103, Cedar Street, New York, 1909. Price 25 c.

8vo volume (pamphlet), containing 185 pages of subject matter, and 72 illustrations. There is an alphabetical index of subjects, and the directions in which both employers and employed are warned and admonished of danger are comprised as:—I. General items of care on the part both of employer and employed: (i.) Physical surroundings. (ii.) Insufficient lighting. (iii.) Overcrowding of machinery. (iv.) Slippery floors. (v.) Ignorance. (vi.) Carelessness. (vii.) Unsuitable clothing. (viii.) Failure to use safeguards provided. (ix.) Overwork. (x.) Ventilation. (xi.) Intoxicants. (xii.) Supervision and management. (xiii.) Rules. (xiv.) Inspections. But the safety devices themselves treated of and described in the work are grouped under the following heads:—I. Steam boilers. II. Engines. III. Electrical apparatus. IV. Elevators. V. The factory. VI. Wood-working machinery.

VAN NOSTRAND'S CHEMICAL ANNUAL, 1909. A Handbook of Useful Data for Analytical, Manufacturing, and Investigating Chemists, and Chemical Students. SECOND ISSUE. Edited by JOHN C. OLSEN, A.M., Ph.D. Constable and Company, Ltd. London, 1909. Price 12s. 6d. D. Van Nostrand Company, New York.

8vo volume, containing 576 pages of subject matter, and the alphabetical index. The early part of the work, consisting chiefly of tables, comprises the International atomic weights for 1909, Mendeleeff's periodic system of the elements, Specific gravity of gases, Tables of physical constants of the elements, Gravimetric factors and their logarithms, Factors for the calculation of indirect gravimetric analyses, Molecular and atomic weights and their logarithms. Next follows a series of tables for the calculation of volumetric analyses. VIII. Basicity of acids with various indicators according to R. T. Thompson. IX. Value of normal solutions of acids and bases. X. Value of normal solutions of oxidising and reducing agents. XI. Value of normal solutions of precipitation reagents. XII. Physical and chemical constants of oils (Seeker). XIII. Physical and chemical constants of fats and waxes (Seeker). XIV. Physical constants of lubricating oils (Lewkowitsch). XV. Physical and chemical constants of representative samples of lubricating oils (Seeker). XVI. Temperature correction for refractive indices of oils. XVII. Temperature correction for specific gravity of oils and fats. XVIII. Conversion of acid value into oleic acid. XIX. Table for calculating the specific gravity of oils at 15.5° C. XX. Polenske value of butter fat. XXI. Conversion of butyro-refractometer readings to indices of refraction. XXII. Reduction of gas volumes to 0 and 760 mm. XXIII. Corrections of barometer readings for temperature. XXIV. Coefficient of expansion of gases. XXV. Density of nitrogen (Dietrich). XXVI. Density of carbon dioxide (Parr). XXVII. Logarithm tables. XXVIII. Physical constants of inorganic compounds. XXIX. Physical constants of organic compounds (E. Emmet Reid, Ph.D., M.A.). XXX. Physical constants of alcohols (A. Seidl). XXXI. Physical and chemical

Books Received.

CHEMIKER-KALENDAR, 1910. Ein Hilfsbuch für Chemiker, Physiker, Mineralogen, Industrielle, Pharmazeuten, Hüttenmänner, u.s.w. Von Dr. RUDOLF BUDERMANX. Einunddreissigster Jahrgang. In zwei Teilen. Julius Springer's Verlag, Monbijouplatz 3, Berlin, 1910. Price M. 4. Bound in leather, M. 4.50.

PART I.—Arranged as a pocketbook, strongly bound in waterproof cloth. It contains an almanack for 1910, together with a table of the more frequently used atomic weights and their multiples. The general text refers principally to matters of purely chemical interest. I. Atomic and molecular weights. II. Different properties of chemical substances. III. Gas and vapour densities. Specific gravities. (1) Alkalis. (2) Acids. (3) Salts. (4) Alcohols, &c. IV. Solubility. V. Analysis. VI. Volumetric analysis. VII. Electrochemical analysis. VIII. Gas analysis. IX. Spectrum analysis. The matter in these various groups is chiefly composed of tables (Hilfstabellen). A notebook calendar with blank pages for notes, is arranged for the different days of the year. The subject matter, exclusive of the calendar and the blank pages for notes, fills 385 pages. A tabular arrangement of the relative coinage values of the world now follows. One side of the external cover of the little volume is utilised as a centimetre scale measure.

PART II.—This supplementary volume is in size similar to the pocketbook, but is unbound, and is more directly concerned with chemical technology. It contains tables relating to:—I. Physics and physical chemistry. II. Mineralogy. III. Technical chemical analysis and investigation. Besides the tabulated matter, however,

constants of essential oils (A. F. Secker). XXXII. Melting point and composition of fusible alloys. XXXIII. Degrees Baumé (American standard) and specific gravity at 60° F. XXXIV. Sulphuric acid. Specific gravity, degrees Baumé and Twaddell. XXXV. Fuming sulphuric acid (T. Winkler). XXXVI. Sulphuric acid (Lunge and Isler). XXXVII. Fuming sulphuric acid (Gnehm). XXXVIII. Nitric acid. (W. C. Ferguson). XXXIX. Nitric acid (Lunge and Rey). XL. Hydrochloric acid (W. C. Ferguson). XLI. Hydrochloric acid (Lunge and Marchlewski). XLII. Acetic acid at 15° (Oudemans). XLIII. Phosphoric acid at 17.5° (Hager). XLIV. Aqua ammoniac (W. C. Ferguson). XLV. Sodium hydroxide solution at 15° (Lunge). XLVI. Potassium hydroxide at 15° (Lunge). XLVII. Sodium carbonate solution (Lunge). &c. LII. Alcohol by volume and weight, per cent. (Gilpin, Drinkwater, and Squibb). LIII. Methyl alcohol (Dittmar and Fawsitt). LIV. Specific gravity of aqueous solutions of chemically pure glycerine (Gerlach and Skälweit). These tables run up to LXXXIV., when a series appears of tables with the fundamental equivalents of metric and U.S. weights and measures, and also of conversion of British Imperial to metric weights and measures. A chapter of Thermochemistry is now approached, and tables LXXXIX to XCIX are devoted to THERMOCHEMICAL UNITS. Heat of combustion of various substances; anthracite coal; bituminous coal; oven coals; lignites; wood; petroleum; natural gas; coal gas; water gas. REVIEW OF CHEMICAL LITERATURE. A classified list now follows of the more important articles that have been published since July, 1906, under Analytical chemistry. General inorganic chemistry. Industrial chemistry. Organic chemistry. Physical chemistry. Radio-activity. NEW BOOKS. List of more important works published since 1906. American and English books. Foreign books, mostly German.

ZUR KENNTNISS DES GERBPROZESSES. [Dissertation.] Von Dr. JOHANN VON SCHROEDER. Sonderausgabe aus den Kolloidchemischen Beiheften, Monographien zur reinen und angewandten Kolloidchemie. Herausgegeben von Dr. WOLFGANG OSTWALD. Band 1. Theodor Steinkopff's Verlag, Dresden, 1909. Price M. 1.50.

Svo pamphlet, containing dedication, introduction, and subject matter filling 57 pages. The matter is classified as follows:—I. The adsorption of tannin by charcoal, alumina, and hide powder. II. Adsorption of tannin by charcoal and alumina from alcoholic solution. III. Course of alteration of concentration of a tannin solution in contact with hide powder. IV. Behaviour of sterilised hide powder-tannin mixture. V. Change of the hide powder during the action of the tannin. VI. Influence of alkali on the adsorption of tannin by hide powder. VII. Adsorption of tannin in alcoholic solution by hide powder. VIII. Precipitation of gelatin by tannin. Influence of acids on the precipitation. I Adsorption of tannin by gelatin. X. Adsorption by gelatin-gel. Influence of salts. Influence of acids. XI. On the nature of the gelatin solution. XII. Similarities in behaviour of hide powder and gelatin. XIII. Theory of tanning. XIV. Summary.

BULLETIN OF THE IMPERIAL INSTITUTE. VOL. VII. No. 3. Price 1s.

This issue contains the results of investigations as to rubbers from Southern Nigeria, Gambia and the Seychelles, goat's hair and mohair from Uganda, tobaccos from Nyasaland, ebony from the East Africa Protectorate, economic products from Fiji, chromite ore from the Transvaal, laterites from the Central Provinces of India, also notes on the occurrence and utilisation of tungsten ores, on iron ores of the Crown Colonies and Protectorates of the British Empire, on the cultivation and utilisation of the soy bean, on agricultural work in Nyasaland, on ylang-ylang oil in the Philippines, on the pearl fisheries of Mergui (Burma), on carnotite from South Australia, etc.

BRITISH AND FOREIGN TRADE AND INDUSTRY. STATISTICAL TABLES AND CHARTS RELATING TO BRITISH AND FOREIGN TRADE AND INDUSTRY (1854—1908.) (IX continuation of certain Tables and Charts contained in the Returns Cd. 1,761 of 1903 and Cd. 2,337 of 1904; with Additions.) [Cd. 4,954.] Wyman and Sons, Fetter Lane, E.C. Price 5s. 2d.

The present return continues and brings up-to-date a number of statistical tables and charts relating to British and foreign trade and industrial conditions, which were included in two volumes prepared by the Board of Trade, and presented to Parliament in 1903 and 1904. (Cd. 1,761 and Cd. 2,337.)

Patent List.

Where a Complete Specification accompanies an Application, an asterisk is affixed. The dates given are (i) in the case of Applications for Patents, the dates of Application, and (ii) in the case of Complete Specifications Accepted, those of the Official Journals in which acceptances of the Complete Specifications are advertised.

Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

I.—PLANT, APPARATUS, AND MACHINERY.

APPLICATIONS.

26,406. Macfarlane. Electrically-driven centrifugal drying machines. Nov. 15.

26,642. Barlow and Lord. Filtering and filters. Nov. 17.

26,696. Rollin and Hedworth Barium Co. Manufacture of anhydrous compounds from crystallised compounds. Nov. 17.

26,726. Sefton-Jones (Rogers). Separation of given substances from mixtures. Nov. 17.

26,938. Soc. Anon. Métallurgique Proc. de Laval. Obtaining a homogeneous mixture of a pulverised material and a gas. [Swed. Appl. Nov. 21, 1908.]* Nov. 19.

26,979. Thwaites. Externally heated kilns. Nov. 20.

27,318. Marie. Apparatus for concentrating liquids. Nov. 24.

27,406. Best. Manufacture of heat insulating material. [Addition to No. 15,829 of 1907.]* Nov. 25.

- 27,457. Garde. Rotary pump for liquids or gases. [Ger. Appl., Jan. 2, 1909.]* Nov. 25.
 27,506. Bone, Wilson, and McCourt. Heating media. Nov. 26.
 27,582. Alexander (Reinhardt). Centrifugal separators. Nov. 26.
 27,599. Lehmann. Composite filtering apparatus.* Nov. 26.

COMPLETE SPECIFICATIONS ACCEPTED.

- 24,528 (1908). Köddewig. Annular kilns. Nov. 24.
 24,937 (1908). Schönmann. Apparatus for introducing gases into liquids. Nov. 24.
 26,910 (1908). Sheppee. Thermostats. Dec. 1.
 6012 (1909). Felten and Guillaume. Lahnweywerke. Mixing devices. Nov. 24.
 8541 (1909). Boulton (Bradley). Drying apparatus for peat, etc. Dec. 1.
 16,615 (1909). Irwin, and Johnson and Co. Filter-presses. Nov. 24.

H.—FUEL, GAS, AND LIGHT.

APPLICATIONS.

- 26,408. Orson. Treatment of low-quality coking coals before carbonising.* Nov. 15.
 26,428. Jones. Treatment of gases from coke ovens or gas retorts. Nov. 15.
 26,432. Pudney and Sadler. Incandescent gas mantles. Nov. 15.
 26,858. Stewart and Stewart. Gas producers and their working. Nov. 19.
 27,051. Stone. Fuel. Nov. 22.
 27,157. Whittaker. Apparatus for extracting tar or other impurities from coal gas, etc. Nov. 23.
 27,158. Whittaker. Apparatus for cooling and washing coal gas or other gases. Nov. 23.
 27,232. Barnett. Calcium carbide cartridges. Nov. 23.
 27,310. Chaney. Manufacture of gas. Nov. 24.
 27,311. Gibbons Bros., Ltd., and others. *See under IX.*
 27,420. Stewart and Stewart. Gas producers and their working. Nov. 25.

COMPLETE SPECIFICATIONS ACCEPTED.

- 17,619 (1908). Fuller. Manufacture of refractory electric conductors. Dec. 1.
 25,299 (1908). Boulton (Bradley). Preparation and treatment of peat. Dec. 1.
 26,475 (1908). Koller. Gas producers. Nov. 24.
 2292 (1909). Blau. Liquefaction of illuminating gas by pressure. Nov. 24.
 2389 (1909). British Thomson-Houston Co. (General Electric Co.). Treatment of electric lamp filaments. Dec. 1.
 9901 (1909). Williams. Gas producers. Dec. 1.
 11,315 (1909). Fisk. Incandescent gas mantles. Nov. 24.
 11,639 (1909). Oswald and Oswald. Suction or pressure gas producer plants. Nov. 24.
 15,078 (1909). Jones. Coke ovens. Dec. 1.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

APPLICATIONS.

- 26,936. Wassmer. Preparation of certain hydrocarbon bodies. Nov. 19.
 27,116. Tanne and Oberländer. Separating solid carbonated hydrogen from residues of mineral oil and tar.* Nov. 22.

COMPLETE SPECIFICATION ACCEPTED.

- 7427 (1909). Coulson. Treatment of tar. Nov. 24.

IV.—COLOURING MATTERS AND DYESTUFFS. APPLICATIONS.

- 26,700. Bloxam (Act.-Ges. f. Anilinfabr.). Manufacture of azo dyes directly dyeing cotton. Nov. 17.
 27,029. Newton (Bayer and Co.). Manufacture of vat dyestuffs. [Addition to No. 7819 of 1909.] Nov. 20.
 COMPLETE SPECIFICATIONS ACCEPTED.
 25,477 (1908). Newton (Bayer and Co.). Manufacture of azo dyestuffs. Dec. 1.
 27,098 (1908). Newton (Bayer and Co.). Manufacture of anthracene derivatives and their use in dyeing and printing. Dec. 1.
 3276 (1909). Newton (Bayer and Co.). Manufacture of dyestuffs of the anthracene series. Dec. 1.
 6086 (1909). Bloxam (Act.-Ges. f. Anilinfabr.). Manufacture of monoazo dyestuffs. Nov. 24.
 20,649 and 20,650 (1909). Chem. Fabr. vorm. Sandoz. Manufacture of substantive disazo dyestuffs. Nov. 24.
 22,200 (1909). Kalle and Co. Manufacture of pure nitro-o-oxazo dyestuffs. Nov. 24.

V. PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

APPLICATIONS.

- 26,497. Longbottom and Ratcliffe. Producing patterns or effects on textile fabrics. Nov. 15.
 27,028. Newton (Bayer and Co.). Dyeing and printing. Nov. 20.
 27,066. Clegg, Hartley, and Slingsby. Apparatus for use in dyeing felt. Nov. 22.
 27,431. Cox. Extracting moisture from cops, cheeses, warps, cotton, wool, etc., after bleaching, dyeing, etc.* Nov. 25.
 27,432. Cox. Apparatus for bleaching, dyeing, or otherwise treating textile materials.* Nov. 25.

COMPLETE SPECIFICATIONS ACCEPTED.

- 24,842 (1908). Cartwright. *See under VII.*
 24,922 (1908). Crombie and Schubert. Apparatus for obtaining fibres from solutions. Nov. 24.
 25,813. (1908) Schirp. Device for dyeing, bleaching, etc., textile materials. Nov. 24.
 27,098 (1908). Newton (Bayer and Co.). *See under IV.*
 7734 (1909). Ransford (Cassella and Co.). Production of print effects on fabrics. Dec. 1.

VII.—ACIDS, ALKALIS, AND SALTS.

APPLICATIONS.

- 26,452. Falding. Apparatus for making sulphuric acid. [U.S. Appl., Dec. 31, 1908.]* Nov. 15.
 26,696. Rollin and Hedworth Barium Co. *See under I.*
 26,868. Mines de Manganèse de Las Cabesses. *See under XV.*
 27,126. Wetter (Riedel). Manufacture of alkali carbonates.* Nov. 22.
 27,168. Hargreaves. Manufacture of soda. Nov. 23.
 27,231. Humann and Teisler. Production of sodium-aluminium fluoride.* Nov. 23.
 27,576. Read. Apparatus for forming solidified carbonic acid gas. Nov. 26.
 27,650. Reese. *See under XV.*

COMPLETE SPECIFICATIONS ACCEPTED.

- 16,924 (1908). Radcliffe. Purification of ammoniac spent liquor. Nov. 24.
 24,842 (1908). Cartwright. Obtaining solutions or pseudo-solutions of ferric oxide, etc., for use in dyeing, etc. Nov. 24.
 1148 (1909). British Cellulose Synd., Ltd., and Merz. Producing a solution of ammoniacal cupric oxide. Nov. 24.
 4465 (1909). Barton. Manufacture of certain lead oxides. Nov. 24.

4872 (1909). Chem. Fabr. Bettenhausen. Production of a permanent ammoniacal solution of cupric oxide. Nov. 24.

6115 (1909). Peniakoff. Manufacture of sodium bicarbonate. Nov. 24.

6822 (1909). Pearlman and Pearlman. Recovery of zinc compounds and ammonia. Dec. 1.

7633 (1909). Jaubert. Manufacture of salts derived from peroxides. Nov. 24.

15,995 (1909). Serpek. Production of compounds of aluminium and nitrogen. Nov. 24.

18,923 (1909). Boulton (Ladd). *See under IX.*

11,263 (1909). Pezzolato. Treatment of pyrite ashes. Nov. 24.

VIII.—GLASS, POTTERY, AND ENAMELS.

APPLICATIONS.

27,127. Thompson. Manufacture of glass from cheap material. [Addition to No. 8974 of 1909.] Nov. 22.

27,253. Kalmykoff. Decorating pottery, glass, etc. Nov. 23.

27,630. Crush. Treatment of china clay. Nov. 27.

COMPLETE SPECIFICATIONS ACCEPTED.

11,633 (1909). Heller and Baumgartl. Manufacture of ceramic ware. Dec. 1.

18,923 (1909). Boulton (Ladd). *See under IX.*

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

APPLICATIONS.

26,681. Waxin. *See under XIII.*

26,693. Earle. *See under XIII.*

27,311. Gibbons Bros., Ltd., Masters, and Van Marle. Refractory bricks and the construction of walls of gas retorts, regenerators, etc., with said bricks. Nov. 24.

COMPLETE SPECIFICATION ACCEPTED.

18,923 (1909). Boulton (Ladd). Treatment of clay, bauxite, kaolin, etc. Nov. 24.

X.—METALS AND METALLURGY.

APPLICATIONS.

26,410. Witter. Separation of zinc and lead from mixed sulphides.* Nov. 15.

26,551. Johnson. Production of steel. Nov. 16.

26,588. Soc. Anon. Electro-Métallurgique (Proc. P. Girod). Refining steel. [Fr. Appl., May 6, 1909.]* Nov. 16.

27,003. Soc. Anon. Electro-Métallurgique (Proc. P. Girod). Refining steel. [Addition to No. 26,588 of 1909.]* Nov. 20.

27,132. Johnson (Chem. Fabr. Griesheim-Elektron). Melting and casting magnesium and its alloys. Nov. 22.

27,201. Allison (International Metal Products Co.). Iron manufacture.* Nov. 23.

27,364. Wynne. Treatment of ores, etc. Nov. 24.

27,558. Lockwood. Treatment of auriferous and argentiferous ores. Nov. 26.

27,609. Brown. Annealing steel of the high-speed or self-hardening type. Nov. 27.

COMPLETE SPECIFICATIONS ACCEPTED.

24,590 (1908). Borchers. Treatment of titaniferous iron ores. Nov. 24.

24,845 (1908) and 8842 (1909). Simpson and Oviatt. Direct production of steel or steel alloys from the ore. Nov. 24.

24,846 (1908) and 5802 (1909). Simpson and Oviatt. Direct production of iron from its oxides or oxide ores. Nov. 24.

5675 (1909). Boulton (Newell Manufacturing Co.). Metal-lising non-metallic articles. Dec. 1.

12,565 (1909) Crispo. Extraction of copper from copper residues. Nov. 24.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

APPLICATIONS.

26,649. New Ignition Synd., Ltd., and Sandy. Electro-lyte for use in electric batteries. Nov. 17.

26,844 and 26,845. Helfenstein. Electric furnaces.* Nov. 18.

27,674. Petersson. Charging electric resistance furnaces. [Swed. Appl., Jan. 7, 1909.]* Nov. 27.

COMPLETE SPECIFICATION ACCEPTED.

2641 (1909). Marino. Treatment of wood for use in storage batteries. Dec. 1.

XII.—FATTY OILS, FATS, WAXES, AND SOAPS.

APPLICATIONS.

27,141. Wild. Manufacture of soap for toilet and other uses. Nov. 22.

27,133. Greer. Compound lubricant. Nov. 25.

XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, &c.

(A).—PIGMENTS, PAINTS.

APPLICATIONS.

26,681. Waxin. Stone preserving paint.* Nov. 17.

26,693. Earle. Priming or paint especially for use on plaster or cement.* Nov. 17.

26,729. Eckford. Manufacture of paints. Nov. 17.

COMPLETE SPECIFICATIONS ACCEPTED.

4465 (1909). Barton. *See under VII.*

8686 (1909). Profes. Paints. Dec. 1.

8967 (1909). Luciani and Battesti. Apparatus for making artificial ultramarine. Dec. 1.

13,848 (1909). Carrick and Pattison. Black magnetic iron hydrate for use as a pigment. Nov. 24.

17,697 (1909). Schott. Waterproof and preserving paints. Nov. 24.

(C).—INDIA-RUBBER.

APPLICATIONS.

27,005. Bloxam (Callender). Manufacture of artificial india-rubber. Nov. 20.

27,130. Dreyfus, Friedl, Bentley, and Clayton Aniline Co. Manufacture and purification of india-rubber. Nov. 22.

27,385 and 27,386. Bradley. Production of artificial rubber. Nov. 24.

27,398. Black and Morton. *See under XX.*

XIV.—TANNING, LEATHER, GLUE, SIZE, &c.

APPLICATIONS.

27,536. Beaulieu. Machine for earrotting hides. [Fr. Appl., Dec. 16, 1908.]* Nov. 26.

27,573. Greaves. Tanning hides or skins. Nov. 26.

XV.—MANURES, &c.

APPLICATIONS.

26,867. Mines de Manganèse de Las Cabesses. Stimulant manure. [Fr. Appl., Nov. 21, 1908.]* Nov. 19.

26,868. Mines de Manganèse de Las Cabesses. Manufacture of suboxides of manganese for use as manures. [Fr. Appl., Nov. 21, 1908.]* Nov. 19.

27,650. Reese. Organic phosphates. Nov. 27.

XVI.—SUGAR, STARCH, GUM, &c.

APPLICATION.

26,557. Epstein. Treatment of sugar or the residue thereof. Nov. 16.

XVII.—BREWING, WINES, SPIRITS, &c.

APPLICATIONS.

- 26,849. Epstein. Treatment of lactobacilline or para-lactic culture or fermentation. Nov. 18.
 27,360. Braasch. Production of yeast. [Addition to No. 10,458 of 1909. Ger. Appl., Nov. 24, 1908.]* Nov. 24.

XVIII.—FOODS; SANITATION, WATER PURIFICATION; AND DISINFECTANTS.

(A.)—FOODS.

APPLICATIONS.

- 26,691. Fairweather (Jensen). Preservation of food-stuffs and the like. Nov. 17.
 26,927. Blenkinsop. Treatment of flour. Nov. 19.

(B.)—SANITATION; WATER PURIFICATION.

APPLICATIONS.

- 26,842. Wetter (Riedel). Softening water.* Nov. 18.
 27,155. Coplans. Rapid preparation of potable water. Nov. 22.
 27,164 and 27,165. Andrews. Water purifying and softening plant.* Nov. 23.
 27,607. Candy and Candy. Apparatus for use in purifying water. Nov. 27.

COMPLETE SPECIFICATION ACCEPTED.

- 11,471. (1909) Didelon and Brant. Apparatus for rendering soluble and nitrifying sewage, &c. Nov. 24.

(C.)—DISINFECTANTS.

APPLICATION.

- 27,006. Little. Manufacture of a cleansing fluid for use as a sheep dip or for disinfecting. Nov. 20.

XIX.—PAPER, PASTEBOARD, &c.

APPLICATIONS.

- 26,657. Parkin and Williams. Non-inflammable celluloid or celluloid substitute. Nov. 17.
 27,102. Panthoier. Manufacture of new acetyl derivatives of cellulose. Nov. 22.

COMPLETE SPECIFICATIONS ACCEPTED.

- 19,735 (1908). Meyer. Treatment of acetyl- and nitro-cellulose for making a plastic material. Dec. 1.
 24,343 (1908). Herz. Apparatus for obtaining pulp from waste paper, etc. Nov. 24.

- 24,811 (1908). Brandenberger. Treatment and application of cellulosic films. Nov. 24.

- 26,573 (1908). Pearson and Stoneham. Manufacture of paper, etc. Nov. 24.

- 8175 (1909). Rinman. Treatment of waste liquors from soda pulp mills. Dec. 1.

- 15,555 (1909). Meister, Lucius, und Brüning. Manufacture on the paper machine of paper having relief-like effect. Dec. 1.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENTIAL OILS, AND EXTRACTS.

APPLICATIONS.

- 26,814. Johnson (Boehringer und Söhne). Preparation of pharmaceutical compounds.* Nov. 18.

- 27,030. Newton (Bayer und Co.). Manufacture of pharmaceutical compounds. Nov. 20.

- 27,357. Chem. Fabr. auf Actien, vorm. E. Schering. Manufacture of curative agents. [Addition to No. 24,505 of 1909. Ger. Appl., Nov. 28, 1908.]* Nov. 24.

- 27,397. Black and Morton. Production of substances of the terpene series. Nov. 24.

- 27,398. Black and Morton. Production of plastic and elastic substances of the terpene series. Nov. 24.

COMPLETE SPECIFICATION ACCEPTED.

- 25,433 (1908). Jensen (Goldschmidt). Manufacture of anhydrides of fatty acids, especially acetic anhydride, from fatty acid salts. Dec. 1.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

COMPLETE SPECIFICATION ACCEPTED.

- 14,502 (1909). Kogel. Method of preparing photographic prints. Dec. 1.

XXII.—EXPLOSIVES, MATCHES, &c.

APPLICATION.

- 27,067. Noad. Manufacture of matches and tapers. Nov. 22.

XXIII.—GENERAL ANALYTICAL CHEMISTRY.

APPLICATION.

- 27,131. Lichtenstein. Instruments for estimating, comparing, or matching tints or colours. Nov. 22.

Journal of the Society of Chemical Industry.

No. 24, Vol. XXVIII.

DECEMBER 31, 1909.

No. 21, Vol. XXVIII.

Official Notices.

NEW HON. FOREIGN SECRETARY AND VICE-PRESIDENT.

Dr. Rudolf Messel has been appointed Hon. Foreign Secretary of the Society in the place of the late Dr. Ludwig Mond, F.R.S.

Prof. A. Liversidge, F.R.S., has been appointed a Vice-President of the Society in the place of Dr. R. Messel, appointed Hon. Foreign Secretary.

CLASSIFICATION OF JOURNAL AND PATENT LITERATURE.

After January 1st, 1910, the Journal and Patent Literature will be classified and entitled as follows:—

1. General Plant; Machinery.
2. A. Fuel; Gas; Mineral Oils and Waxes;
B. Destructive Distillation; Heating; Lighting.
3. Tar and Tar Products.
4. Colouring Matters and Dyes.
5. Fibres; Textiles; Cellulose; Paper.
6. Bleaching; Dyeing; Printing; Finishing.
7. Acids; Alkalis; Salts; Non-metallic Elements.
8. Glass; Ceramics.
9. Building Materials.
10. Metals; Metallurgy, including Electro-Metallurgy.
11. Electro-Chemistry.
12. Fats; Oils; Waxes.
13. Paints; Pigments; Varnishes; Resins.
14. India-Rubber; Gutta-Percha.
15. Leather; Bone; Horn; Glue.
16. Soils; Fertilisers.
17. Sugars; Starches; Gums.
18. Fermentation Industries.
19. A. Foods;
B. Water Purification; Sanitation.
20. Organic Products; Medicinal Substances; Essential Oils.
21. Photographic Materials and Processes.
22. Explosives; Matches.
23. Analytical Processes.
24. Miscellaneous Abstracts.

CHARLES C. CRESSWELL, *Secretary*.

Birmingham Section.

Meeting held at Birmingham University on Thursday,
October 21st, 1909.

DR. T. SLATER PRICE IN THE CHAIR.

MODERN DEVELOPMENTS OF THE GAS INDUSTRY.

BY WM. B. DAVIDSON, PH.D., D.S.C., F.I.C.

On the 9th of June, 1810, the Bill promoting the incorporation of the Gas Light and Coke Company of London, the first public gas undertaking, received Royal Assent. The actual inventor of gas lighting, William

Murdoch, was an engineer in the employment of the famous firm, of Boulton and Watt, Soho, Birmingham. Whilst in their service he found time to bring to a successful issue experiments on the distillation of coal which he had begun in his youth. In 1792 he installed gas lighting in his house at Redruth. In 1803 part of the Soho works was lighted by gas, but it was not till 1807 that a distinct advance was made when the large cotton mill of Messrs. Phillips and Lee, Manchester, was fitted with a complete gas installation. Progress was naturally very slow at first. Presently other pioneers, notably Clegg and Winsor, entered the field. The latter was the principal mover in the formation of the first gas company. During the past half century the development has been very remarkable, and to-day the proportions of the industry have attained huge dimensions.

A rough estimate of the annual production of gas, coke, and residuals by the gas-works of the United Kingdom is given below:—

	Quantity.	Value.
		£
<i>Materials used—</i>		
Coal for gas making	tons 16,000,000	10,000,000
Oil	galls. 60,000,000	700,000
Oxide for purification	tons 70,000	80,000
Lime	?	?
<i>Products sold—</i>		
Gas	cubic ft. 190,000,000,000	24,000,000
Coke, breeze and dust	tons 8,000,000	5,000,000
Ammonia as sulphate	" 165,000	1,800,000
Tar (coal and C.W. gas)	" 900,000	900,000
Sulphur in spent oxide	" 70,000	100,000
Cyanogen as sodium prussiate	" 3,000	90,000
Spent lime	" ?	Practically nil.
Retort carbon	" 5,000	7,500

Approximately 11 per cent. of the gas made is carburetted water gas.

On the Continent, the magnitude of the gas industry, relative to the population, is much smaller. The total quantity of coal carbonized for gas in Germany is only 5½ million tons per annum, 25 per cent. of which comes from England. Coal in Germany costs on an average about 20s., whilst coke is sold at 25s. a ton.

In the United States carburetted water gas bulks more largely in the public supply than coal gas. I have not been able to obtain definite estimates of the gas-making materials used in that country.

During the eighties and nineties the rate of increase in the output of gas in this country was seven or eight times the rate of increase in the population. Naturally this extraordinary development could not be maintained for very many years, and so it is not surprising that the last decade has witnessed a considerable slackening in the demand for town gas.

I have compiled from "Field's Analysis" the gas outputs for 24 of the largest gas undertakings in the United Kingdom for the years 1888, 1898, and 1908, together with the decennial percentage increments for the two intervals in question.

The Metropolitan companies, it will be observed, are making less rapid progress than the provincial undertakings, whilst London suburban companies shew an abnormally high rate of increase. This is only what might have been expected. It is gratifying from the manufacturer's point of view that in spite of economies in the consumption of gas for lighting purposes, the ever-growing competition of electricity for the supply of light and power, and the introduction of producer-gas plants in large factories, the average rate of increase in the output of gas is still more than double the rate of increase of the population.

Gas output of 24 of the largest undertakings of the United Kingdom.

Name.	Millions of cubic feet.			Decennial percentage increase.

If we analyse the figures for individual years we find that the weather is the most important factor to be considered as affecting the consumption. In particular the presence or absence of fogs has a marked effect. Now that a very considerable proportion of town gas is used for industrial purposes we also find a reflection of the state of trade in the annual records of the gas-works. Thus it may happen that a curve representing the annual output of gas for a given town may be somewhat irregular and may even exhibit an occasional fall. The incomes from the different by-products are subject to the market fluctuations which are sometimes rapid and unforeseen. The cost of coal and oil also varies from time to time and thus the selling price of gas is subject to frequent alteration. The case of Birmingham will serve to illustrate these fluctuations. The following diagram indicates the progress made during the last 30 years, the curves representing (1) the output of gas, (2) the price of gas, (3) the income from coke, (4) the income from ammoniacal liquor, (5) the income from tar.

The following figures are compiled from "Field's Analysis" for the year 1908 for 27 gas undertakings representing 50 per cent. of the total gas industry of the United Kingdom. It permits of an interesting comparison of materials carbonized, capital employed, price of gas, quality of gas prescribed and supplied and the burner used for testing purposes.

GAS LIGHTING.—The introduction of the upright incandescent mantle by Auer von Welsbach about the year 1886 for a time threatened to have a prejudicial effect on the development of coal gas just as the modern metallic filament lamp has given electricity undertakings cause for alarm. In the one case the duty of one cubic foot of gas was increased from 3 to 20 candles, in the other the efficiency as compared with the carbon filament lamp has been trebled. The Welsbach mantle, however, has proved a blessing to the gas industry in the later days of competition. The last decade has seen the introduction of the inverted mantle which gives a higher efficiency than the upright, is easier to handle, and lends itself to more artistic arrangement of the fittings. Inverted burners are now much used in small units of 10 to 30 candles, a further economy in the lighting of small rooms being thus effected.

With gas at 2s. 6d. per 1,000 cubic feet giving an efficiency of 20 candles per cubic foot, 1,000 candle-hours cost, for gas only, 1.50d., whilst with electricity at 3½d. per unit and Osram lamps giving an efficiency of 0.90 candle per Watt the same amount of light costs, for electricity only, 3.90d.

Much ingenuity has been expended in the improvement of burners and mantles, and new devices are continually

appearing on the market. We would seem to be within measurable distance of the ideal burner which can be turned on or extinguished by tap or switch without the aid of by-pass. Incandescent gas lighting can only be rendered reliable, however, by attention to the burners, maintenance of a uniform gas-pressure of two to three inches (water gauge) and fairly uniform calorific value. Flat flame burners, on the other hand, do not require a greater pressure than two or three-tenths of an inch. Some gas companies now undertake maintenance of the burners of consumers in the belief that a little attention of this kind is more appreciated than a small reduction in the price of gas. The increase of pressure in the gas mains has not proved to be a cause for alarm so far as leakage is concerned.

Street lighting and the illumination of large rooms is accomplished most effectively by high-pressure gas consumed in burners of special construction fitted with strong mantles. There has been considerable development along this line during the last five years. This would have been much greater had it not been for the additional expense entailed by the erection of compressing plants for the different installations. When high-pressure gas is supplied from the gas-works in special mains such as are being laid in Birmingham and some other towns, no extra outlay on the consumer's part will be necessary and he will thus be able to derive immediate benefit, whilst the streets will have the full advantage. The best type of high pressure burner has an efficiency of 60 candles per cubic foot, that is, three times as much as the ordinary burner. The pressure required is about 50 inches (water gauge) or 2 lb. per square inch. The cost for gas only at 2s. per 1,000 cubic feet (assuming a lower price for gas in bulk), is thus only 0.40 of a penny per 1,000 candle-hours. To equal this figure electricity must be supplied with flame arcs (efficiency, three candles per watt) at 1½d. per unit. So successful has high pressure gas proved itself for street lighting that electric arc lighting already installed has had, in a large measure, to give way to it. Berlin, which is looked upon as the foremost city in Europe in the matter of street illumination has decided in favour of the inverted high-pressure gas-lamp, and it would appear that London is going to follow suit judging from the fact that a deputation of the Streets Committee, after visiting and carefully examining the systems of lighting in some of the principal Continental cities, recommended in July last "that high-pressure incandescent gas-lamps with inverted burners should be adopted as the illuminant; but where gas is impracticable, electricity with open arc and flame arc lamps should be installed." I think this must be looked upon as a great victory for gas lighting.

GAS HEATING.—Hitherto the gas fire has not been regarded as an economical means of heating a room, however convenient it may be, and owing to defects of construction in older types it had acquired somewhat of an evil reputation. Within the last year or two, however, great improvements have been made.

It has been generally recognised that radiation must play an important part in the heating of a room, and the capacious bed of "fuel" has been abandoned in favour of single-row tubular pyramid "fuel." An elaborate piece of research on a gas fire of the modern type referred to has been carried out at Leeds University. The results were published in June last, and the conclusions are as follows:—1. The total radiation from an open gas fire is about 32 per cent., and this is unaffected by the amount of ventilation through the room. 2. No carbon monoxide escapes under ordinary conditions into the room, and very little is ever found in the flue. 3. About 30 per cent. of the heat generated in the stove passes directly into the flue. This figure varies with the volume of air passing through the stove flue. 4. There is no necessity for products of combustion to enter the room and cause discomfort. 5. Reflectors may be usefully employed to produce a sensible increase of radiation into the region where it is most wanted.

A thermal efficiency of 70 per cent. (half by radiation, half by convection) is probably more than three times as much as that of a good coal fire. Gas of a nett calorific

value of 540 B.Th.U. per cubic foot at 2s. 6d. per 1,000 cubic feet gives 18,000 heat units for a penny, whereas coal of a calorific value equal to 14,000 heat units per lb. at 18s. 8d. per ton (1d. for 10 lb.), gives 140,000 units, or eight times as much. On this basis a gas fire is more than twice as costly as a coal fire. Nevertheless, just as the special advantages of electric power under certain circumstances outweigh the doubling or trebling of the cost per brake horse power as compared with gas or steam, so the convenience, cleanliness and labour-saving of the gas fire recommend its use to the average householder. With reductions in the price of gas and further improvements in the appliances, it is not too much to hope that gas fires will be more generally used in the future. From the point of view of smoke abatement this is a consummation devoutly to be wished.

Mr. Onslow, Superintendent of the Gas Factory, Royal Arsenal, Woolwich, a pioneer of high pressure gas lighting, has done much to bring into prominence the utility of high pressure gas for rapid heating and high temperature. The advantages of pressure gas over the ordinary blowpipe lie in the simplicity of the fittings and the ease with which the pressure can be altered at will. The furnaces now used with high pressure gas for annealing shells, &c., in the Arsenal are of the simplest construction, and work with coal gas at 2½ lb. pressure. Temperatures of 1600° C. can be attained without much difficulty in small furnaces and thus most metals can be melted. There is reason for believing there will be important developments in this branch of the industry before long.

GAS FOR COOKING.—In most well-equipped households the gas-cooker is regarded as a necessary adjunct of the kitchen. The fitting of a thermometer through the side of the oven—not a usual practice, but one to be recommended—and the use of a quadrant or slow movement tap, render it easy to regulate the oven-temperature to a nicety without opening the door, thus ensuring complete success every time—a great consideration with both manufacturer and consumer. Attempts to effect economy by preheating the air required for combustion by means of the waste products have hitherto proved only partially successful. Stoves fitted with appliances for hot water circulation are now on the market.

Some years ago slot or prepayment meters for both lighting and cooking were introduced. In this class of business it is the usual practice to supply meter and fittings free, but to charge the gas at a higher rate. In many towns prepayment consumers are in the majority. The system has been a powerful agent in popularising gas lighting and cooking amongst the working classes.

GAS FOR MOTIVE POWER.—Some 30 years ago the indicated thermal efficiency of the best gas engines was only 16 per cent.; to-day it is 37. To show the position of gas as regards cost of motive power the following estimates of the cost of a brake horse power hour, and the data on which they are based, for steam, gas, and electricity, may be useful:—

	Thermal efficiency,		Cost per B.H.P. hour,
	per cent.		d.
Steam . . .	6	Fuel, 14,000 B.Th.U.'s per lb., at 7s. 6d. per ton	0.16
Gas	30	Gas, 540 B.Th.U.'s per cu. ft., at 18s. 8d. per 1000 cu. ft.	0.31
Electricity	86	1d. per unit	0.65

The above figures only include fuel, solid or gaseous, and electric energy. Labour costs are not reckoned. The fuel required with a suction gas plant is said to work out at only one-tenth of a penny per B.H.P. hour, but in this case the cost of gas manufacture must be added. Without entering into a discussion of the relative merits of different sources of motive power, suffice to say that the perfecting of the gas engine has greatly stimulated the demand for town gas for power purposes in recent years.

So multiform are the applications of gas that *gas supply* has become quite a science in itself, apart from *gas manufacture*. This has been recognised by the City and Guilds of London Institute whose examination papers are now set year by year since 1908 in *gas supply* as well as in *gas engineering*.

QUALITY OF GAS.—Throughout the country the proportion of gas sent out during daylight hours has continued to increase in a satisfactory manner. To-day not a few gasworks boast of a day load exceeding 50 per cent. of the total, and as only a small proportion of the nightly output is consumed in flat flame burners one may well ask the question: "What is the utility of the test of illuminating power in such cases?" Gas engineers are in the habit of complaining of the injustice of the tests and restrictions imposed on town-gas. Some have expressed the view that gas should be as untrammelled in this respect as electricity. This opinion represents one extreme. You will find the other in the words of Prof. A. E. Armstrong, quoted from his presidential address delivered to the Chemical Section of the British Association at Winnipeg last August. Speaking of the gas industry he said: "On the engineering side it had been carried to a high pitch of perfection, but on the chemical side it had ever fallen, year after year, to a lower state. The quality of coal gas was such, especially since the withdrawal of the sulphur clauses from Acts of Parliament by which the industry was regulated, that gas was almost unusable. Had not chemists entirely unconnected with the gas industry vastly improved the methods of burning it, gas would long since have fallen into disuse."

Let us look at this question for a moment. The very rich coal gas of 30 years ago is no longer required. In those times it was not practicable to make anything but rich gas because of the low temperatures of carbonization that were available. There is no disputing the assertion, however, that town-gas has been on the down-grade for some years, in respect to both illuminating power and calorific value, which to a certain extent go hand in hand. The Metropolitan has always been looked to for a lead in these matters. Gas referees were established in London by the Act of 1868. At the same time Sugg's No. 1 London Argand burner was adopted for testing the gas for candle-power. The gas was burnt at the rate of 5 cubic feet an hour on a bar-photometer and tested against the standard given by two candles. This method continued in use in London until 1898 when the table photometer and ten-candle pentane standard were introduced to give greater refinement in testing. The gas was now not consumed at the rate of five cubic feet an hour, but at a variable rate so as to give a light equal to 16 candles. The sulphur clauses were abolished by the London Gas Act of 1905, and the ammonia tests were given up. Previously the limit to sulphur other than in the form of sulphuretted hydrogen had been 17 grains per 100 c. ft. in summer, 22 in winter; the limit for ammonia being 4 grains per 100 c. ft. At the same time the No. 1 Argand burner, which at the time of its inception was supposed to be capable of obtaining the highest possible duty from the gas, was discarded in favour of a superior contrivance, the Metropolitan Argand Burner, No. 2, which, chiefly by virtue of an air-damper, gets about 10 per cent. better value out of 16 candle coal gas, and still more out of lower-grade gas or mixed gas. The South Metropolitan Co. and the Commercial Co. received the further privilege of a reduction in standard from 16 to 14 candles. Testing for calorific value was inaugurated, but no restriction was imposed. Quite recently the Gas Light and Coke Co. obtained Parliamentary sanction for the absorption of the West Ham Co. and a reduction in standard from 16 to 14 candles as tested by the new burner. The Gas Company did not get things all its own way, however, and an additional restriction in the form of a calorific value test was imposed. The gas undertaking is now bound to supply town gas of a calorific value not less than 496 British Thermal Units per cubic foot, nett, but will only be penalised when the figure falls below 446½. Most gasworks, I take it, would gladly submit to these dual tests in preference to their present exacting illuminating power standard. Table III. gives one some idea of the variety

of the methods in present use for ascertaining candle-power. In addition to those mentioned there are several types of flat flame and 15-hole Argand burners in use. The difference between two tests with different burners may be as much as six candles. Differences of two candles may be obtained by artificially altering the atmospheric conditions of a badly-constructed photometer-room. It is no wonder then that the relegation of the illuminating power test to a subsidiary position will be welcomed by both engineer and chemist.

Tests for sulphuretted hydrogen and ammonia do not intimidate the gas manufacturer. In these days of perfected mechanical appliances and methods, the escape of sulphuretted hydrogen into the town mains is a very rare occurrence; ammonia, on the other hand, is too valuable to lose.

One of the questions of the hour in the gas industry is: "What quality of gas is called for?" Regard must of course be had to modern conditions of high carbonizing temperatures, vertical retorts, chamber-ovens, and other improved gas-making plant, and to the fact that high candle-power as tested by flat-flame or Argand burner is no longer a necessity. A conference of 40 German gas-chemists answered the question in May last as follows:—(1) A standard calorific value of 544 B.Th.U. per cubic foot, gross value, say, 450 nett. (This is the standard observed by the Berlin municipal gas undertaking, it may be remarked.) The calorific value, they further state, should be as uniform as possible, and should not fall below 524 gross, or say 472 nett. (2) Tests of illuminating power are superfluous. (3) A proportion of 25 per cent. of carbon monoxide is permissible in mixed gas. (4) The gas must always be completely purified from sulphuretted hydrogen, but seeing there is at present no process which can be applied on a practical scale for the removal of other sulphur compounds, which exist only in minute quantities in the purified gas as usually supplied, no limit can be fixed for this. (5) Restrictions of the amounts of ammonia, cyanogen, naphthalene, carbon dioxide, oxygen, nitrogen, and of the specific gravity are unnecessary.

I think I should be giving expression to the opinion of gas chemists in this country by saying we agree with all the above conditions but No. 2. In the use of town gas a luminous flat or round flame is sometimes absolutely necessary, and as the manufacture of a non-luminous gas of the required calorific value is not an impossibility, it is advisable to stipulate an easy standard of, say, 12 candles with the No. 2 Argand burner. By the way, this burner is not the very best obtainable. The Grafton burner of similar type is slightly better. Either will suit the purpose, however. The volume percentages of the different non-essential ingredients in gas of average quality, as now generally supplied, not purified by lime, are as follows:—Carbon dioxide, 2 per cent.; nitrogen, 2 to 16 per cent.; oxygen, 0.6 per cent.; naphthalene, 0.001 per cent.; hydrocyanic acid, 0.03 per cent.; carbon bisulphide 0.02 per cent.

GAS MANUFACTURE. Under no real obligation to produce gas of high candle power, and with strong competition to face on all sides, the gas engineer has set himself to reduce costs of gas manufacture by every means in his power. The various methods that have been adopted to this end may be briefly reviewed:—

1. *Working with smaller retort charges* or lengthening the period of distillation gives greater yield of gas per ton of coal, but labour costs increase and this method is not to be recommended.

2. *A higher temperature of distillation* affords a ready means of increasing the output of gas, and has been resorted to quite generally throughout the country. Iron retorts were discarded in favour of clay retorts many years ago; while direct firing is now to be found only in some small works.

Heating by means of producer gas generated under the retorts and the use of the regenerative effect instituted by Siemens came into general use twenty years ago. In this way not only was the yield of gas increased but the consumption of fuel was greatly diminished. Coal which formerly produced 9,500 c. ft. per ton gave 11,000

or more. The fuel used per 100 lb. of coal carbonized with direct fires is about 25 lb., with generators 18, and with generators constructed with regenerators, 15. There were some disadvantages however. Capital and maintenance charges were largely increased. Naphthalene, a high temperature product of destructive distillation, made its presence felt, as there were now insufficient heavy hydrocarbon vapours present to hold this substance in solution when condensation took place. Naphthalene trouble kept the distribution department at its wits end for some years. The symptoms were numerous blockages in the small pipes or services and the stoppage of the gas supply. These occurred principally in the summer and autumn. In aggravated cases, mains on the works were also blocked. The fact that stoppages occurred more frequently in July, August, and September is accounted for by there being a wider range of temperature during these months as between day and night. Gas saturated or nearly saturated with naphthalene at summer heat was sent out during the day and deposited its naphthalene as the pipes cooled down in the chilly evening. The amount of naphthalene in gas saturated at 60° F. does not exceed 0.008 per cent. by volume, whilst the average amount present in town gas is less than one-sixth of this, and this of it is carried forward to the burner to be consumed. Naphthalene, however, forms very voluminous crystals: as small a quantity as three grains may occupy a volume of one cubic inch. The stoppages were detrimental in three ways. They entailed a great deal of expense in removal; they curtailed the consumption of gas; and they gave gas a bad name. After years of suffering two or three reliable cures were at length discovered. One consisted in washing the gas on the works with a heavy oil—creosote or anthracene oil—so as to remove the great bulk of the naphthalene, and another in adding the vapours of suitable oils to the gas without removing any naphthalene on the works, the oil only taking effect when condensation commenced. The former method depreciates the quality of the gas to a serious extent unless 4 or 5 per cent. of benzol be previously added to the oil.

A combination of the two methods, whereby the gas is washed so as to cause the removal of a small portion of the naphthalene and rendered sufficiently rich in the vapours of oils of the necessary vapour tension, is probably the most economical and reliable way of dealing with the naphthalene difficulty. The oil most suitable for vaporizing has been found to be crude naphtha, distilling to the extent of 90 per cent. between 140° and 260 °C. Less expensive oils such as light kerosene, first runnings from the distillation of carburetted water gas tar, or even carburetted water gas tar itself, have been found more or less effective. With a little attention, a complete cure can be effected and maintained at an expense which is trifling when one takes into account the enriching value of the oil added.

Some idea of the extent of the trouble and the completeness of the cure may be gathered from the figures for Birmingham, where the curative process was begun in 1906.

Naphthalene complaints.

1904.	1905.	1906.	1907.	1908.
16,646	22,748	530	95	46

Another difficulty which became intensified was "stopped pipes." This trouble is rendered the more acute the higher the temperature, the older the coal, that is the less volatile matter it contains, and the lighter the charge. It entails loss of gas and considerable labour costs. It has been overcome by increasing the size of the ascension pipes, by a proper system of augering the same, and by introducing a small quantity of steam or a drip of water.

As very high temperatures were attained the defects of fireclay material also became a source of trouble, a portion of the retort setting not infrequently giving way.

Greater attention has therefore had to be given to the quality of fireclay goods. Steps have already been taken by those interested in the fireclay industry with a view to improving and standardising refractory material for use on gas-works.

3. *A combination of large charges with high temperatures* represents the acme of perfection of modern methods of carbonization. Under similar conditions of temperature and exhaust the make of gas per ton is not so great in this case as with smaller charges but the quality is decidedly better. The effect of putting a large charge into the retort is to diminish the free space above the coal and to lessen the degree of degradation of the hydrocarbons to carbon and hydrogen. The carbonizer finds he can use more exhaust to bring the gas down to standard, hence the prevalent erroneous idea that heavy charges give a larger yield of gas per ton of coal. An analysis of the gases will show an increase in nitrogen.

Possessing the advantage of a 14 candle standard with No. 2 Argand burner, some gas engineers have been at a loss to know how to manufacture gas of this low illuminating power with the plant at their disposal. The simplest way of doing it is by "over-pulling," but this can only be done at the expense of the calorific value of the gas. One occasionally hears in these days of abnormally high makes of 12,500 to 13,000 c. ft. per ton from ordinary coal carbonized in horizontal retorts, and the success is sometimes erroneously attributed to the marvellous working of mechanical devices such as retort-house governors, dry hydraulic-main, or steam in the ascension pipe. I think it is much to be deplored that gas-engineers have found themselves compelled to resort to dilution of the gas by "over-pulling." The percentage of nitrogen has gone up very considerably in many large towns in England—not in Birmingham, I may say. In some cases it is as high as 16 per cent. This is one way of making low-grade gas—it is assuredly not the best way. The accepted practice in this country is to carbonize at level gauge, that is, to maintain the gases in the retorts at atmospheric pressure on the average. Working with a retort-house governor and a dry hydraulic main this gives a gas containing 4 to 7 per cent. of nitrogen, which might be regarded as permissible—the theoretical amount is always less than two per cent. The German gas engineer goes to the other extreme and instead of "over-pulling" maintains an average pressure in the retorts of about one inch (water column). The gas then contains about three per cent. of nitrogen, but there is undoubtedly considerable loss through leakage into the furnace.

4. *NEW PLANT.* Manufacturing costs have been appreciably reduced not only by higher production of gas but also by new machinery. A great deal of mechanical ingenuity has been expended in the construction of stoking appliances. Two of the best known of the older types are the "West" machine working with compressed air and the "Arrol-Foulis" working with hydraulic power. Of the latest machines the "De Brouwer projector" which throws the coal off a revolving belt and the "Fiddes-Aldridge" machine which fills and empties the retort at one stroke are among the most successful. Both the last-named are as a rule electrically driven. The machine most in demand for modern carbonizing practice is one that can almost completely fill the retort, the discharge being effected by a "pusher."

Inclined retorts were introduced into England in 1885. They are usually set at an angle of 32° and dispense with stoking machinery. There are difficulties in charging them satisfactorily. Much depends on the nature and size of the coal and as a rule they take only the normal charge of six to seven cwt. A few settings of retorts have been set at 45°, at which angle it is possible to work with full charges.

Vertical retorts. A great advance in carbonizing has been made by Dr. Buch of Dessau who brought out the vertical retorts in 1906. The main advantages of the Dessau system over the horizontal and inclined retorts in common use may be enumerated as follows:—1. Higher yield of gas per ton of coal, and per unit of ground area. 2. Gas is nearly free from naphthalene. 3. The yield of ammonia is considerably increased. 4. The tar is thinner

and contains less free carbon. 5. The coke is large and dense. 6. Steam may be admitted with advantage at the end of the carbonization period to make a certain amount of water gas. 7. The work is easier for the men.

There are now over 4,000 Dessau retorts in use on the continent. Some are four metres in height and take charges of 10 cwt. of coal every ten hours. Others are five metres long and take a corresponding larger charge. An installation of sixty Dessau retorts, the first of its kind in England, has just been completed in Sunderland.

English engineers have not been idle meanwhile. Theirs is the higher ambition to perfect a continuous process of charge and discharge in vertical retorts. This is an ideal system of distillation which will no doubt achieve ultimate success. At present only a few retorts of this type are at work—some on the "Woodall-Duckham" and some on the "Glover-West" system. The mechanical difficulties have been largely overcome, but so far the carbonizing results are somewhat disappointing.

Chamber-ovens. Attention is now being turned to the adaptation of the large coke-oven to gas-making. Chamber-ovens are already competing with vertical retorts. Here again we have to thank our German friends for the innovation. The original Munich chamber-ovens were inclined, but they are also being built horizontally and vertically. The charge in the largest size is about seven tons. Their advantages over vertical retorts are:—1. Still lower carbonizing costs. 2. Superiority of coke and elimination to a great extent of night work. No accurate information is so far available with regard to gas, liquor and tar. It is safe to say that want of uniformity in the gas made must militate against their adoption on small works.

The following is a rough comparison of the carbonizing costs (charging, drawing and firing) per ton of coal for the different systems.

	Old machinery, labour, horizontals.	Inclined retorts.	New machinery, horizontals.	Verticals.	Chamber- ovens.
pence.	pence.	pence.	pence.	pence.	pence.

RESIDUALS. Let us now briefly consider what progress has been made in the production of residuals.

Coke, Breeze and Dust. The sale of coke has been encouraged by paying strict attention to the sizing. It is now the usual practice to screen the coke so as to produce large coke, small coke, one inch breeze, breeze, pea breeze and dust to suit the requirements of different classes of customers. There is a steady sale of considerable quantities of "small coke" for household use. Coke-dust formerly sent to the tip is now sold for use in boiler-furnaces where special fire-bars and forced draught are used. At some works, particularly in Germany, coke dust is mixed with tar and converted into briquettes which find a ready sale.

In 1907 patents were taken out for the manufacture of what was described as a new smokeless fuel called Coalite. The material is now produced on a fairly large scale by the British Coalite Company at Wednesfield and Plymouth. This fuel is the product of coal carbonized at a temperature of 1000° F. as against 1800° for ordinary gas coke. In the process of manufacture the gas made per ton of coal is only about 5000 cubic feet, half of the total volatile matter of the coal remaining in the coke. The tar obtained is about 20 gallons and is of a light nature and particularly rich in paraffins. The yield of ammonia is 70 per cent. of that produced at high temperature. Coalite ignites more readily than ordinary gas coke and burns with more flame, but it is only slightly better in heating efficiency.

In view of its greater efficiency and smokelessness, as compared with coal, coke merits a much larger sale for household purposes than it at present enjoys.

Ammoniacal liquor.—There is little to be said regarding this residual. Synthetic nitrogenous manures, such as

nitrolime, have hitherto failed to prejudicially affect the sale of ammonium sulphate. A considerable quantity of gas-liquor is now converted into strong ammonia both in this country and on the continent. This is found to be much more remunerative at present prices. Quite a large number of gas works possess a sulphate plant which in its improved modern construction is easily controlled. The extraction of ammonia from crude coal gas in these days of perfected mechanical appliances is very complete indeed. In the final washing with a rotary washer of up-to-date construction one may confidently expect an efficiency of 99 per cent.

Tar. Since the discovery and development of the aniline dyes, coal tar has had an attraction for the young research chemist. The unfortunate fact remains that 30 years ago tar fetched nearly double the price that it does to-day. The cause of the fall in price is the usual one—the supply is greater than the demand. Quotations depend largely on the market for pitch. As a dressing for roads a new use has been found for gas-works tar. It is said to preserve the surface of the road from disintegration and suppress the dust nuisance. Its use is accompanied by diminution in the expenditure on road cleansing, watering and maintenance. Carburetted water gas tar is of slightly less value than coal-tar. Special use has been found for it in the manufacture of naphthalene solvent. It yields a good kind of pitch which finds a use in the manufacture of special varnishes.

Spent oxide.—One of the troubles in purifying the gas by means of oxide of iron has been "back-pressure" caused by the oxide settling down in a compact mass, and thus offering excessive resistance to the passage of the stream. This has been remedied in a large measure by alterations in the design of the grids supporting the material. Various kinds of oxide ore are employed, but they are being displaced to quite a large extent by "artificial oxide" prepared from the burnt spent oxide. This material is inactive towards sulphuretted hydrogen immediately after coming from the kilns but after exposure to the action of air and water for a prolonged period and treatment with a little lime and copperas it is able to do its work satisfactorily, especially when lightened by the addition of sawdust or similar material. Nearly all the spent oxide of the gas-works is used for the manufacture of sulphuric acid. A small proportion is bought by a few chemical works for the extraction of Prussian-blue and sulphocyanide. This is said to be a profitable business only when the oxide contains at least 5 per cent. of the former ingredient. Lime for purification has been largely discarded, especially in the South of England.

Cyanogen extraction.—Ten or 12 years ago and occasionally since then prussiate of soda crystals were quoted at 4½ and 5 pence per lb. The price has been dwindling down for some time and during the present year it has stood at threepence. At the former figure a handsome profit could be made if the plant was sufficiently large to treat at least two million cubic feet of crude gas per day. At the present time few are bold enough to erect expensive appliances for the sake of cyanogen recovery. In the absence of a cyanogen recovery plant the impurity (only 0.2 per cent. by volume of hydrocyanic acid) is removed to the extent of about 80 per cent. by the oxide through which it has to pass. Prussiate processes on the Foulis, Davis-Neill, or similar systems are now in operation at seven or eight large gas-works in England.

A description of the various processes would carry us too far. Suffice it to say that ferrous hydrate, sulphide, or carbonate mud is the essential ingredient, the base being either ammonia, soda, or lime, or a combination of these. One of the great difficulties experienced has been to find a suitable washer to deal with a heavy sludge. The Holmes brush rotary washer is employed with success when the mud is thin but troubles ensue when the sludge is inclined to be gritty or thick. The highly ingenious washer patented by Feld in 1906, though not so high in efficiency as one would like, gets over this difficulty very satisfactorily.

It is more profitable to treat the gas before removing the ammonia. On the continent the Bueb prussiate process is very generally employed in the larger works. The

method consists simply in running a strong solution of copperas from time to time into a rotary washer. The sludge containing soluble and insoluble prussiate is sold to chemical works.

The British Cyanides Company's patented process of extraction has been in operation at a number of moderate-sized works for some years. In this process sulphur is added to strong ammonia liquor in a suitable washer to form polysulphide which takes up the hydrocyanic acid to give sulphocyanide. The resultant product is sold in the form of liquor to the chemical works.

DEVELOPMENTS IN PURIFICATION.—*Carbon bisulphide.* Under the old restrictions of the sulphur clauses, lime had to be employed on a large scale. This was sulphided so as to remove the carbon bisulphide as thiocarbonate. At the same time a large proportion of the carbon dioxide present was eliminated. With the repeal of the clauses the use of lime became no longer necessary except where no better means could be found of maintaining the illuminating power. It is possible to gain one "candle" by removing all the carbon dioxide, but all things considered it has generally been found unprofitable to do so. When the sulphur clauses were enacted the incandescent burner was not known. The diminution in the consumption of gas for a given candle power with incandescent burner was thought to be good cause for removal of the sulphur restrictions. Nevertheless the elimination of organic sulphur, as it is called, would be a welcome gain to the gas industry, for there is no gainsaying that the formation of even minute quantities of sulphuric acid in a room cannot but be harmful to furniture as it is to metallic fittings.

It is not likely that lime purification will again be resorted to on account of its tediousness, high cost, and uncertainty, and the difficulty of removing the malodorous product. Some hope of success is held out by the large scale experiments of Mr. Hall, of Portland, Oregon, the results of which have been recently published. Mr. Hall has adopted the expedient recommended by Mr. Vernon Harcourt 50 years ago of simply heating the gas leaving the purifiers to a temperature of 700° to 900° C. The probable reaction that takes place is represented by the equation $\text{CS}_2 + 2\text{H}_2\text{O} = 2\text{H}_2\text{S} + \text{CO}_2$. The heating takes place in brick chambers and the gas is afterwards purified a second time with iron oxide. The great bulk of the organic sulphur is said to be removed in this way, but nothing is known as to costs.

Liquid purification.—Seeing that a purifier-box must be opened more or less frequently with attendant dangers of firing of the oxide by rapid revivification, the loss of gas and the subsequent admixture of a large quantity of air when the box is again put to work, a process of liquid purification in closed vessels has been much sought after by gas manufacturers. Partially successful attempts to solve the problem were made in the eighties by Hills, Claus, and Holgate. The processes then experimented with depended on the action of purified ammonia, obtained by the distillation of the gas liquor, in absorbing hydrogen sulphide and carbon dioxide. The experimental plants that were erected were discarded one by one. Their failure was due to the following causes:—1. Loss of ammonia; 2. incompleteness of the reactions; and 3. the costly nature of the plant and the supervision necessary.

Two or three years ago Dr. Feld launched a scheme for condensing and purifying coal or coke-oven gas. The gas was to be taken as hot as possible, say at 200° C., from the retorts and treated in a series of centrifugal washers. The tar was to be fractionated by hot washing into pitch, dry heavy tar and dry light tar. It was intended to extract ammonia in two washers and sulphuretted hydrogen in another set of two. One washer was to be used as a cooler. Thus it was proposed to perform the whole process of condensation and purification in one small building under the supervision of one man. Attempts have been made to work the process in Germany, but so far as I can gather, without complete success. There have been naphthalene and other troubles. The idea is brilliant and, I think, well worthy of a sustained effort to put into execution.

In the extraction of sulphuretted hydrogen Feld makes use of its reaction with sulphur dioxide. He at first used

certain oils as the medium for carrying the sulphur dioxide and sulphur, the latter of which eventually crystallised out. This method has been abandoned in favour of a process which has been in operation on a small scale at Königsberg and has just been started on a larger scale at one of the Hull gas-works, where 1½ million cubic feet per day are being dealt with. The active agent is zinc thiosulphate solution, made in the first instance by the action of sulphur dioxide on zinc sulphide formed from zinc oxide and sulphuretted hydrogen. Two Feld washers are used in the process and the reactions that take place are represented by the equations:—

The most recent proposal by Feld is one that ensures a very complete extraction of ammonia to form sulphate simultaneously with the removal of sulphuretted hydrogen. It necessitates an elaborate chemical plant, however. The process is explained by the following equations:—

1. First washing:

2. Regeneration of iron liquor:

3. Second and further washings:

4. Oxidation: $2\text{FeS} + 2(\text{NH}_4)_2\text{S}_2\text{O}_3 + 3\text{SO}_2 + 4\text{O}$

Then follows the filtration of the sulphur.

5. Final precipitation of iron:

Then follows the filtration of ferrous sulphide, leaving a pure solution of ammonium sulphate.

NEW APPLIANCES.—*Gas washers.*—Professor Burstall of Birmingham University, who also has a scheme for the fractional separation of tar, has recently devised and patented a gas-washer and a fan tar-extractor the ingenuity of which appeals to everyone.

Among the washers that have been introduced in recent years may be mentioned the Holmes brush washer, the Feld vertical centrifugal washer already referred to, and the new vertical centrifugal washer of Messrs. Kirkham, Hulett, and Chandler. The last named is very similar in its action to the Feld washer.

Gas governors.—In the works the retort-house governor is coming into general favour. It ensures greater uniformity of gas. The use of district governors to regulate the pressure to consumers' meters is also being extended with beneficial results.

Gas calorimeters.—The "Boys" calorimeter was introduced by the Metropolitan Gas referees in 1905. It agrees closely in results with the Junkers and Simmance-Abady instruments and possesses peculiar advantages of its own.

Pyrometers.—Of new instruments the Wanner electrical pyrometer is largely used in Germany. The Féry radiation pyrometer is in greater favour in England and France. The latest modification is the Féry radiation spiral pyrometer—a very simple and compact mechanism capable of taking temperatures of combustion chambers and retorts with the greatest convenience and celerity.

Recorders.—*Pressure.*—In a gas-works it is highly desirable to have a record of pressure or vacuum at inlet of retort-house governor, inlet of exhauster, inlet of purifiers and outlet of holder. Every well-equipped works takes daily records of this kind.

Carbon Dioxide.—Daily records of carbon dioxide in the waste gases from boiler furnaces, in crude carburetted water gas, or even in waste gases from retort settings, are of great assistance in controlling manufacture. Several ingenious contrivances for this purpose are now supplied.

Calorimetry.—One of the latest advances is the recording calorimeter. Junkers' firm supply an elaborate and accurate calorimeter recording gross value. Messrs

Parkinson and Cowan supply a very simple mechanism which records nett value. These instruments are of immense value to the gas-manufacturer as they promptly indicate any want of uniformity in the quality of the gas made, and this affords opportunity of rectifying a defect without delay. This is all the more important in these days when the uniformity of calorific value is so essential.

Carburetted water gas.—In most gas-works possessing a carburetted water gas plant this auxiliary to coal-gas is only used either as a stand-by or as an enriching agent. That it is much cheaper to manufacture than coal gas is, I believe, the general opinion of the outsider. With oil at a comparatively high figure, as it has been for some years, carburetted water gas is probably on an average slightly dearer than coal gas, candle for candle.

One cannot say that any important improvements in water-gas manufacture have been made in the last ten years.

Research work.—There have been no contributions of great practical importance to our knowledge of the chemistry of carbonizing.

Improvements have been mainly physical and mechanical. The reactions that take place in the retort are as yet but little understood.

I would remind you of the bold experiment made by the Birmingham Gas Department in erecting five years ago as a test-plant a complete gas-works carbonizing 24 tons of coal per day. Hitherto we have not published any results, chiefly for commercial reasons. I may confidently say, however, that the remarkable improvement in the carbonizing results of the different works of the Department is in large measure attributable to the test-works, and justifies the considerable expense of its erection and working.

DISCUSSION.

After some remarks by Dr. R. LESSING,

Mr. H. T. PINNOCK said he was pleased to see in the town gas industry that it was found necessary to use producer-gas for heating the retorts. For lighting purposes town gas held pride of place; but for power and heating purposes the claims of Mond gas must be considered. His experience was that suction gas did not come fully up to expectations; while the cost of labour and water, associated with such a plant, and the waste of time in starting up, took away much of the efficiency of the plant. He desired to know whether the new Fery spiral pyrometer was as accurate as the thermo-couple type.

Dr. DAVIDSON: Very nearly; they agree closely.

Mr. PINNOCK, continuing, said he regarded the recording calorimeter as a useful invention. His firm were unfortunately situated, in that they had an apparatus which no one else had. No one was able to work it, except the professor who made it. It was made to satisfy the requirements of the Board of Trade, in order that the gas might be tested at any time; and when an official came he would probably be unable to use it. He was much interested in Professor Burstall's new tar extracting fan. He understood a test had been made and that the fan brought out the last traces of tar from the gas.

Mr. N. P. BOOTH asked how to detect minute traces of carbon monoxide in air—this being a problem with which he was recently faced?

Mr. R. B. BATTY said he regarded Victoria Square, Birmingham, as the experimental lighting area and supposed it was the show place of what could be produced at Saltley. A friend of his, who knew Europe well, looked upon that part of Birmingham as the best gas lighted area he had ever seen. Alluding to the observations as to the naphthalene trouble the gas experts were to be congratulated upon getting rid of the nuisance. In the statistical record on the prices of gas Dr. Davidson was not ashamed to state the price charged at Sheffield. He was glad to hear that high pressure gas would be

given without any great cost or inconvenience to the gas department.

Mr. WALTER asked whether it was necessary to use specially designed retorts where, as in Germany, a higher working pressure was maintained in order to bring down the percentage of nitrogen in the gas; also whether the ordinary fire-clay retorts could be used in the above case.

Dr. DAVIDSON, in reply, said in the coal gas industry the best return to be obtained from ordinary gas-coal was a conversion of 25 per cent. of the calorific value from the solid into gaseous form. With regard to producer gas 75 per cent. could be obtained. It had been suggested that towns should be supplied with producer gas, rather than coal gas, by reason of the lower cost of production. One important consideration, however, was the heavy cost of distribution, as huge holders and mains were necessary for distributing producer gas. He was not aware of a satisfactory calorimeter for accurately testing producer gas. As to the retorts in use in Germany where a comparatively high pressure was maintained, they were of the ordinary fireclay type, as used in this country, and there was found to be a certain leakage into the furnace and therefore loss of gas. The test for carbon monoxide was iodine pentoxide; the particulars being given in the *Journal of Gas Lighting* of June 22nd, 1909, p. 823. With reference to street lighting in Birmingham he was rather ashamed of it, with the exception of that in Victoria Square. They were very much behind Continental towns. In Germany where there was a lower grade gas incandescent lighting was far better. There the organisation and supervision of the lighting were superior, and the gas itself showed greater uniformity. When the new 24 in. main was laid in Birmingham the central streets would be much better lighted than they were to-day. On the question of price, Sheffield, which had a lower figure than Birmingham, was favourably situated, being near the coal mines. They paid three to four shillings per ton less for their coal than the Birmingham Corporation. They were also able to obtain a great deal of cheap slack. Sheffield was not however the lowest in price although it was the lowest in the list of the twenty-four largest towns. Widnes supplied gas at 1s. per 1,000 c. ft.

Canadian Section.

Meeting held at Montreal on Friday, October 22, 1909.

DR. MILTON HERSEY IN THE CHAIR.

ETHYL ALCOHOL FROM SAWDUST AND OTHER WOOD WASTE.

BY PROF. R. F. RUTTAN, M.D.

The action of the zymase of yeast upon glucose and certain other fermentable sugars is the one source of the ethyl alcohol of commerce. It therefore follows that the problem of how to produce ethyl alcohol in a more economic manner can only be solved by finding a new and cheaper method of obtaining solutions of fermentable sugars.

The fermentable sugars employed in the preparation of alcohol have been derived hitherto from a number of sources, which may be generally stated to be (1) the products of the hydrolysis of starch and allied substances by means of an amylase; (2) solutions of sugar obtained directly from fruits, &c., and the non-crystallizable by-products of sugar works, &c.

The cost of alcohol from these sources is much too great to enable it to compete with other products in many fields where it could be used to great advantage. This is due, not so much to the cost of manufacture as to the cost of the raw material from which the fermentable sugar is obtained. The most economical source of starch on this Continent is Indian corn, yet this raw material costs at

present \$21.60 per ton. One ton of corn gives about 90 gallons of alcohol of 94 per cent. at a cost of 24 cents per gallon for raw material. About two gallons of raw molasses produce 1 gallon of 94 per cent. alcohol, and this raw material costs 21—22 cents. The raw material of German alcohol has been estimated to cost 20 to 21 cents per gallon of alcohol of this strength.

There is a process in which a waste product of nominal commercial value is the raw material from which fermentable sugars can be obtained. The actual cost of sawdust and other wood waste to any industry is difficult to estimate. In some localities, where the quantity of waste is not great, a local market for it has been established, and in most forms it has been disposed of at a small profit. The larger mills, now that electricity is of such general application, have in many cases increased their power and find an economic outlet for all forms of wood waste as fuel for generating this power. There remain, however, the great majority of the large sawmills of this continent where the wood waste has either to be disposed of by sawdust burners at a cost of about 20 cents per ton, or allowed to accumulate in heaps upon the land, or is turned into an adjoining stream to be a nuisance and an injury for many years, if not for generations.

Any industry employing wood waste situated in the vicinity of a large mill of the last-mentioned class, should be able to obtain waste for the cost of transportation and handling which under moderately favourable conditions should not exceed 30—50 cents per ton.*

As I shall later explain, one ton of sawdust or other comminuted wood waste calculated to a dry basis can be made to yield about 20 gallons of alcohol of 94 per cent. This then reduces the cost of raw material from 20—24 cents to 2 or 2½ cents per gallon of alcohol.

That fermentable sugar can be produced from wood has been known to chemists for nearly a century. Braconnet as early as 1819, by heating wood cellulose with sulphuric acid, produced a pulp which contained glucose. The sulphuric acid, however, could not be economically removed. Since then no process has been devised until quite recently for hydrolysing cellulose and allied bodies economically.

Numerous attempts have been made to solve this problem and the list of patents on the subject is a large one. Prior to 1900, when the Classen patents were taken out, the hydrolysing effect of many acids on starch and the celluloses had been studied and the processes patented. C. Pope, for instance, in 1898 obtained a patent for hydrolysing starch and obtaining fermentable sugar by sulphuric acid, and Einar Simonsen in 1898 a patent to make sugar or glucose from sawdust by the action of dilute sulphuric acid (see this J., 1898, 365, 481, 1164). Sulphurous acid had long been used to make wood pulp from comminuted wood before these patents; it was also well known that when sulphurous acid was heated with wood, sulphuric acid was always formed which took part in the reaction, and its action was prevented in pulp-making by the use of calcium bisulphite, the sulphuric acid combining with the calcium as it was produced.

Dr. Alexander Classen of the Polytechnic School of Aachen, stated in 1900 that sulphurous acid in aqueous solution under pressure converted the cellulose of wood into glucose and that the product could be fermented in the usual way yielding ethyl alcohol. He patented this process all over the world, but the original methods as stated in the patent proved to be crude and unworkable. The claim is as follows:—

"The process of converting cellulose into sugar, which consists in heating the cellulose in a closed vessel at a temperature of 120°—145° C. with a solution of sulphurous and sulphuric acids substantially as described." (This J., 1900, 1028; 1901, 734, 1908.)

After successful experiments in a test plant erected by Classen in Aachen, a similar plant on a larger scale was erected at Highland Park near Chicago, to demonstrate to American capitalists its possibilities. The results were so satisfactory that a larger plant on a commercial scale was

erected at Hattiesburg, Miss. The plant included the following elements:—

1. An acid apparatus where the solution of sulphurous acid was prepared and where the excess of sulphur dioxide after use could be re-absorbed and saved for further utilisation.

2. A revolving cylinder, 30 feet long, and about 36 inches in diameter, which formed the converter or digester.

3. An exhausting battery consisting of a series of tanks in which the sugar was washed from the partly converted sawdust by hot water.

4. Neutralising vats in which the various acids remaining in the saccharine liquid were neutralised by calcium carbonate.

5. Fermentation vats, and a still, where the process was completed as in an ordinary distillery.

The wood waste was introduced into the digester (which it nearly, but not completely filled), made of iron lined with lead to prevent action of the sulphuric acid, and surrounded by a steam jacket by which it was heated. This revolving cylinder had a capacity of about two tons. To the charge of wood waste was added a weight of a nearly saturated solution of sulphur dioxide corresponding to about one-third of the raw material. The drum was closed air-tight and steam turned into the jacket while the whole slowly revolved. The temperature of the interior was thus slowly raised to 290°—300° F., and the pressure to about one hundred pounds. After from four to six hours the sulphurous acid and steam were blown off into the absorbing tanks and the sulphur dioxide thus partially recovered. The cover was removed and the contents emptied looking then very like finely ground coffee. This finely divided, treated wood was conveyed to the exhaustion batteries and the sugar extracted. The liquid obtained, contained from 350—400 lb. of sugar for each ton of raw material treated. The next steps were to neutralise the acid liquid, allow it to clear by subsidence, pump it into the fermentation vats, ferment it by yeast and distil the product in the usual way. It was claimed for the process that each ton of wood waste gave about 18—20 gallons of absolute alcohol.

The history of the original Classen process is an excellent example of how a process which will give very good results on a laboratory scale, and good results even on a larger experimental scale, will just fail to succeed when magnified to a size necessary for working on a commercial basis. Even the strongest supporters of the original Classen process do not now believe it to be a success as a money-making proposition.

The difficulties in the way to success for this process are explained to be: (1) The length of time necessary to convert 1½ to 2 tons of wood, this requiring from 4 to 6 hours; (2) the quantity of acid required; (3) the prolonged action of so much acid and water in the rotating converter reduced the wood to a very fine powder and formed much sulphuric acid which, acting on the sugar and other substances, produced gums and caramels, and so made the complete extraction of the sugar from the residue very tedious and expensive. (4) The buckling and breaking of the lead lining of the converter, which had to be repaired after every two or three operations, and proved a very great source of delay and expense.

The plant built in the United States, which is reported to have cost for building and working for a year about \$250,000, has not been used for some time. Two chemical engineers, Malcolm F. Ewen and G. H. Tomlinson, who were associated with the Classen process, both in Germany and the United States, finding the original process unlikely to prove a commercial success, obtained substantial financial aid from a Chicago engineer, Mr. J. M. Ewer, and in 1904 began experimenting along new lines to overcome the difficulties which prevented the old process from being a success. The result of their researches and experiments has been to shorten the time of the hydrolysis in the converter from six hours to 40 or 45 minutes, to obtain the treated wood waste in a form which could

* Tenders have been offered to deliver, 200 yards away, 200 tons of sawdust, etc., per day at 25 cts. per ton.

be quickly and efficiently extracted, to devise a converter which is not in the least degree affected by the process, to reduce the quantity of acid employed, and to obtain a very uniform and large yield of fermentable sugar from wood waste.

This process, by the courtesy of the patentees, I was enabled to study in June, 1909, at Chicago Heights, about 20 miles from the city of Chicago. The plant was erected by the Wood Waste Products Company, now called the Standard Alcohol Company, which has control of the Ewen-Tomlinson patents. This experimental plant was composed of units of commercial capacity, and was set up in workshops in the grounds of a large machinery manufactory. It consisted of the same elements as those required for the older process, *viz.*, the acid generating and recovery apparatus, a converter or digester, a battery of diffusion cells to extract the sugar, neutralising and storage tanks, fermentation vats, and a distillery.

The converter in use at Chicago was a revolving cylinder, 12 feet by 8, of steel, lined with fire-brick, and set in a cement of lead oxide and glycerin. It had a capacity of about two tons of shavings or three of sawdust. The wood waste, sawdust, shavings, or small chips, are dumped into the converter, which is completely filled, and is then closed air tight. Gaseous sulphur dioxide in measured quantity, only about 1 per cent. by weight of the dry wood, is introduced through a perforated tube passing through the trunnions of the cylinder and thus through the centre of the revolving mass of the sawdust. When the required quantity has been added the sulphur dioxide is turned off and live steam is introduced through the same tube till a pressure of about 100 lb. is reached. It takes from 10 to 15 minutes to get the contents of the digester heated up to the required temperature. The steam is then cut off and the digester revolves slowly for another 40 to 45 minutes, the temperature and pressure being kept constant, when the hydrolysis is complete. The steam, carrying with it the terpenes, the excess of sulphur dioxide, and some acetic acid, is then discharged into the absorption tank. The manhole is again opened and the coffee-coloured chips and sawdust discharged into a V-shaped bin which supplies the conveyors going to the diffusion cells.

In the plant now being built for the Du Pont Powder Company at Georgetown, S.C., it is probable there will be three or four converters, egg-shaped or spherical, and capable of taking four to five tons at one charge. These are to be so arranged that when the digestion in one is completed the steam and acid may be directly discharged into a second digester already filled with wood waste, thus saving time and expense in recovering the acid of each charge.

From the converter the treated wood is conveyed to the extraction battery where it is rapidly and effectively exhausted by hot water, the acid liquid neutralized with slaked lime and carbonate, allowed to settle in the settling tank, and then pumped to the distillery, fermented and distilled.

In the tests I made of the plant two charges of the converter were used. The first contained 3623 lb. of shavings from Chicago Mills, air dry and almost entirely pine. This carried 18.61 per cent. of moisture, making the dry wood equivalent 2948.8 lb. The second charge consisted of 2992 lb. of shavings and 2105 lb. of wet hardwood sawdust, consisting chiefly of oak but with some pine. The total weight of the second charge was 5097 lb. with a dry wood equivalent of 3058 lb. This second charge was made with a view of testing the effect of the process on sawdust carrying a very high percentage of moisture. The sawdust gave on analysis 70.4 per cent. moisture.

The product of the action of steam and sulphur dioxide on the first charge of shavings was a friable brown product resembling tan bark or coffee, with a fragrant aromatic odour and strongly acid. Analysis of this gave:

	per cent.
Moisture	32.23
Total reducing sugars	13.70
Calculated to dry basis	20.20
Total acidity (as sulphuric acid, H_2SO_4)	1.23
Sulphuric acid (H_2SO_4)	0.418
Reducing sugars, fermented	10.70
Unfermented sugars, xylose, etc.	3.00

The wood waste in the second charge after treatment resembled the heated shavings, but was finer and had a powerful aromatic odour and gave the following results:

	per cent.
Moisture	34.63
Total reducing sugars	14.28
Calculated to dry basis	24.18
Total acidity	1.12
Sulphuric acid	0.353
Reducing sugars, fermented	10.97
Non-fermented matter, xylose, etc.	3.21

The total weight of waste wood in the form of sawdust and shavings in these two charges was 8760 lb., or calculated to a dry basis, 6007.1 lb.

The treated wood was then exhausted with hot water in the extraction battery. The liquid containing the sugar from these two charges was collected in one storage tank and occupied a volume of 2984 gallons, or 26,150 lb. in weight. The mingled liquors contained 5.6 per cent. of reducing sugars calculated to dextrose.

The total acidity was 0.64 per cent. calculated to sulphuric acid; of this 0.21 per cent. was sulphuric acid and the balance was composed of acetic acid, a little sulphurous acid, and aromatic compounds of the type of pyrogallol. The presence of the polyphenols and tannin bodies was most obvious. On neutralizing this solution with lime and calcium carbonate it blackened rapidly and when ready for fermentation had an inky colour due to the oxidation of the aromatic salts. The liquid also contained a considerable amount of furfural. As there is little or no nitrogenous material suitable for yeast food in the liquor it does not ferment well alone, hence before adding the yeast about half a bushel of malt sprouts was added to a vat of 3000 gallons as food for the yeast.

In this experimental plant various forms of yeast have been tried. The problem as to which particular breed of yeast will give the best results was, in June last, still unsolved. The yeast used in my experiment was brewers' yeast from a neighbouring lager beer brewery which was found to give constant and regular fermentations, but not more than 75 to 80 per cent. of the theoretical yield of alcohol was obtained. The fermentation occupied about three days, when the liquid was handed over to the gauger and distiller who was an employee of the United States Government, and placed in charge of the distillery. From the 2984 gallons of fermented fluid, corresponding to 6007.1 lbs. of dry wood the gauger reported 115.92 gallons of proof spirit or 61.66 gallons of 94 per cent. alcohol.

This will be seen to be equivalent to 20.55 gallons per ton of wood waste calculated to a dry basis, or 14.14 gallons per ton of wood waste including the wet sawdust which contained over 70 per cent. of moisture. This alcohol when rectified to 94 per cent. is of a potable spirit, crystal white, and carries no trace of odour or flavour of wood. It contains no trace of methyl alcohol or of the higher alcohols such as fusel oil but, gives the reaction for traces of furfural and aldehyde.

At present there has been little or nothing done towards utilizing or indeed determining the quantity and value of the by-products resulting from the manufacture of ethyl alcohol by this process. The Standard Alcohol Company have contented themselves with manufacturing a very cheap and pure ethyl alcohol and have left the working out of the by-products to the future.

The wood waste left behind after complete extraction is a friable cellulose and represents about 65% of the original wood, of which only about one-third is rendered soluble and extracted by the process. This material, according to the present plan, is to be squeezed between rollers, dried partly by waste heat from the boilers and used as fuel. Turpentine and acetic acid are found in the absorption tanks after blowing in the steam from the converter and will no doubt be recovered.

In France there is in operation another process for the manufacture of ethyl alcohol from wood waste. I know nothing of this process beyond an account of it which appeared in the General Electric Review of September, 1909, by G. U. Borde. The claims for this process are interesting and extraordinary. Finding the Classen process

unworkable on a commercial scale the company who controlled those patents for France are reported to have so modified the process as to largely increase the value of the by-products, chiefly the acetic acid and the solid tailings, and can still produce about 20 gallons of alcohol per ton. The raw material is treated in a Classen converter with a solution of sulphurous acid at a pressure of 100 lb. Neither the time required—a most important item—nor the form of the converter nor yet the quantity of acid used are stated in the report. From the profound change effected in the character of the wood, however, the process must be greatly prolonged and the sulphuric acid formed given ample opportunity to attack the cellulose. The digested mass is allowed to partly cool in the digester when it is found to have shrunk about 25 per cent. The sulphurous acid is recovered and the material from the digester passed over to a separator in which the acetic acid is recovered by vapourizing it with steam. The whole mass, without any attempt at separating the sugar, is then neutralized, made into a mash, which is fermented and distilled in the same way as an ordinary grain mash is handled in a whisky distillery.

The tailings from the still are compressed and dried as in the previous process by waste gases from the boilers. This material is claimed to be useful as a stock food, or can be briquetted or mixed with magnesia to form artificial stone of value. In an experiment conducted by the writer I am quoting, he obtained from 3200 lb. of refuse wood 21½ gallons of 94 per cent. alcohol, 76 lb. of acetic acid and 1800 lb. of stock food. The value of this he estimates as follows:

Alcohol at 40 c. per gall.	\$ 8.60
Acetic acid at 6 c. per lb.	4.56
Stock food at \$23 per ton	17.25
	<hr/> \$30.41
Estimated cost of production	7.00
Net profit	<hr/> 25.41
	<hr/> \$30.41

If this be a true estimate of the value of the products obtained from a ton and a half of sawdust it is much more profitable than the process I have reported upon. The ethyl alcohol produced according to the above is of secondary importance both commercially and economically to the manufacture from sawdust of a food-stuff for stock of greater value than Indian corn. The description of the process does not convince one that the inherent difficulties of the Classen process have been removed. The exaggerated value placed upon the stock food is obvious. There is no reason, however, why a prolonged digestion of wood at a high temperature should not greatly increase the yield of acetic acid and might produce a substance from cellulose by the hydrolysing effect of sulphuric acid which might have a food value, but necessarily a very low one after the extraction of the sugar. It is known that the partial hydrolysis of keratin (horn, hoof, hair, etc.), renders such substances digestible. If the process be carried so far as this, however, it seems very probable that the sulphuric acid formed would destroy much of the sugar and thus lower greatly the yield of alcohol. In the Ewen-Tomlinson process which I have studied, it was found that the more rapidly the contents of the digester could be raised to the required temperature the shorter was the time required to produce the maximum yield of sugar; a gradual elevation of temperature, as occurs in the Classen process, induces secondary reactions and a lower yield of fermentable sugar. This rapid heating of the contents of the converter is only possible by the Ewen-Tomlinson method of introducing live steam into the interior of the mass by the perforated tube in the axis of the converter.

All will watch with interest the development of these two offsprings of the Classen process in America. A plant is being erected to use this French process at Hadlock, Wash., and another is proposed for some place in Ontario.

As to the cost of production of ethyl alcohol by the Ewen-Tomlinson process, a very close estimate has been made, based upon tenders and the experience of the

patentees in the Classen plant. Broadly speaking, the cost is about the same as that required to produce alcohol from grain or any other starchy material. Outside the converter itself there is nothing used in the plant which is not quoted on the market and made for other purposes. Without going into details, a plant capable of handling 100 tons of dry sawdust in a ten hour day, or working continuously, 200 tons per day, including buildings of a simple character and of cheap substantial construction, was estimated at \$99,500. The daily cost of maintenance, including interest, depreciation, labour, and material, allowing 50 cents per ton for the sawdust or other wood waste, would amount to \$217, i.e., \$217 for 100 tons, or \$2.17 for 20 gallons of alcohol, 90 per cent., or a net cost of 10.8 cents per gallon. No allowance is here made for fuel, save the cost of drying the unused portion of the sawdust. This estimate further is made on a plant not smaller than 100 tons.

When one considers the possible value of the by-products from a large plant, and the fact that quite 20 per cent. of the available sugar was not fermented in the experiments made last June, it would appear that cheap industrial alcohol has at last arrived.* Ethyl alcohol from grain, 94 per cent., averages about 52 cents to the consumer without the Government tax, and denatured alcohol from 45 to 60 cents. Alcohol made from refuse wood should not cost the consumer more than 20 to 25 cents.

Quite apart from its economic aspect, the manufacture of fermentable sugar from wood by this process is intensely interesting to the chemist. The process is essentially one of hydrolysis analogous to the conversion of starch to sugar by the amylolytic ferments. The celluloses are, like starch, polysaccharides of unknown constitution. They are generally represented as having the same percentage composition and empirical formulae, and just as we can represent the hydrolysis of starch to maltose and dextrose, so we can show how by the assimilation of water the cellulose can give rise to maltose and dextrose. It is assumed that it is the cellulose element in the wood which gives rise to the sugar.

I was much struck by the regular action of sulphurous acid upon the sawdust, a constant quantity, about 35 to 40 per cent. of the wood, only being attacked. We know from the studies of numerous chemists, such as Hugo Müller, Sachs, Cross and Bevan, and others, that wood freed from adventitious constituents such as the tannins, colouring matters, resins, &c., is strikingly uniform in the composition of its fundamental tissues, notwithstanding the great variety in structural complexity, and this uniformity in composition is not confined to species, but is found to embrace all sorts and varieties of woody tissue. The average composition of wood from all sources may be said to be, water 11 per cent., cellulose 50 per cent., soluble in water 3.5 per cent., non-cellulose 35.5 per cent. Lignum vitae and ebony are exceptions, being very low in cellulose and high in non-cellulose.

In the Classen patents and in one of the Ewen-Tomlinson patents it is the cellulose which is claimed to be converted into fermentable sugars. It seems more than a coincidence that the quantity of material hydrolysed in the Ewen-Tomlinson process should be so constant and should correspond so closely to the proportion of non-cellulose found in woods. In all processes of hydrolysis the non-cellulose or lignone complex is the first to break down whether the hydrolysis occurs in an acid or an alkaline medium. There is every evidence that here the lignone complex is broken down. The presence of hydroxy-derivatives of benzene, of pentoses, acetic acid, and furofural in quantity is obvious in the liquid extract of the treated wood. It seems probable that the lignone complex in woods is attached to a certain proportion of cell cellulose (hemi-cellulose) as well as to the oxy-cellulose and perhaps to the true fibre cellulose.

The material left after treatment consists of cellulose which is found on being again submitted to steam and sulphur dioxide to yield but a trace of sugar. True fibrous

*The Standard Alcohol Company claim to be able to produce this alcohol at a cost of 7 cents per gallon in a large plant.

cellulose (absorbent cotton) in another experiment remained unattacked. Its physical as well as its chemical properties were practically unchanged.

Under the conditions of the process a small quantity of sulphurous acid is employed for a short time only and very little sulphuric acid is formed. It would seem that the acid acts here as a catalyser inducing a rapid hydrolysis of the lignone complex and of a proportion of easily attacked cellulose. The oxy-cellulose for the most part and the true cellulose present are not seriously altered chemically. It would seem possible that, authorities to the contrary notwithstanding, the lignone complex is capable of yielding a certain amount of fermentable sugar. Should this, on further study, prove to be the case, it might be possible to treat pulp wood by this process as a preliminary to its conversion into pulp, and then by a second treatment to produce pulp fibre from the unattacked residue.

There is little doubt that in the original Classen process there was, owing to the larger proportion of acid and the prolonged action, a more profound action on the cellulose and the lignone complex, as well as probably a secondary action on the carbohydrates produced.

In a lumber producing country like Canada, any industry that can utilise waste wood and give it commercial value should receive encouragement. If this be the "revolutionary discovery," which the Department of Agriculture at Washington has pronounced it to be, it will add much to the wealth of nations. It will not only open up new fields for the use of industrial alcohol, but will liberate for use as food the million of bushels of grain now used up in the manufacture of ethyl alcohol, 90 per cent. of which is used as a luxury in life and regarded by many as a distinct evil in the community.

MR. MAX M'SPRATT IS THE CHAIR.

A RAPID METHOD FOR THE DETERMINATION OF ZINC IN THE PRESENCE OF IRON.

BY JAMES M. TAYLOR.

The published volumetric methods for the determination of zinc in the presence of iron require a preliminary treatment to obtain a pure zinc solution. This usually means the separation of copper, lead, and bismuth by hydrogen sulphide. The excess of hydrogen sulphide is boiled off, and iron oxidised. Precipitation by ammonia or ammonium acetate, in the presence of ammonium chloride, throws down ferric hydroxide with varying amounts of zinc; this is dissolved in acid, and reprecipitated by ammonia, the process being repeated till the filtrate is free from zinc. In most methods it is also necessary to remove manganese before estimation of zinc. The precipitation of zinc sulphide in the presence of chloroacetic acid is not complete if chlorides are present. These separations require too much time, and methods involving them were not useful on that account. A method of titrating zinc in the presence of iron seemed, therefore, a necessity.

Zinc sulphide is precipitated when hydrogen sulphide is passed into a dilute neutral solution of a zinc salt, with the liberation of an equivalent of acid. Ferrous salts,

under similar conditions, are unaffected. An endeavour was made to utilise these facts, by titrating the free acid liberated with caustic soda, using methyl orange as indicator.

Hydrogen sulphide was added to a mixture of zinc and iron sulphates, and normal caustic soda run in from a burette; towards the end of the titration "clots" of ferrous hydroxide were formed where the caustic soda dropped into the liquor, which did not readily dissolve. The white zinc sulphide first obtained darkened when the neutral point was reached. The further addition of about 0.2–0.3 c.c. of caustic soda gave an almost black coating of ferrous sulphide. The results were not satisfactory.

Sodium carbonate was tried instead of caustic soda, with some success, and pointed to the possible additional advantage of using bicarbonate. The latter was adopted with immediate success, and concordant results were obtained.

The use of methyl orange as indicator was abandoned, and the point when all zinc was precipitated and ferrous sulphide commenced to be thrown down, giving a greyish chocolate colour to the precipitate, was taken as the end point.

The following is the method employed for the determination of zinc in solutions containing ferrous salts, supposing them to be free from lead and copper—5 or 10 c.c. of the liquor are measured into a 600 c.c. flask 20 c.c. of a saturated solution of ammonium chloride, and a drop of methyl orange solution are added, and the solution neutralised with $N/2$ sodium bicarbonate. About 100 c.c. of water saturated with hydrogen sulphide are added, and then $N/2$ sodium bicarbonate is run from a burette, at first at the rate of about 2 or 3 drops per second. The contents of the flask must be well shaken throughout the titration. Each drop of sodium bicarbonate as it touches the liquor gives a black precipitate which *instantly* dissolves. Should the black precipitate of ferrous sulphide not form, it is a sign that insufficient hydrogen sulphide is present. When the zinc sulphide commences to turn grey, the sodium bicarbonate is added more slowly, shaking for four or five seconds after the addition of every 0.1 c.c. Finally, one drop will change the colour to a decided chocolate, when the titration is finished. 1 c.c. of $N/2$ sodium bicarbonate solution is equivalent to 0.016 gm. of zinc. The sodium bicarbonate solution is made by dissolving 42 grms. of bicarbonate in water and diluting to one litre. The solution is stable, but it is advisable to titrate a known amount of zinc alongside the sample till the operator becomes accustomed to the end point, taking the sample to the same depth of colour. The bicarbonate solution is standardised as follows:—0.15–0.25 gm. of zinc is measured into a 600 c.c. flask, and 20 c.c. of saturated ammonium chloride solution and about 0.1 gm. of ferrous sulphate are added. The solution is neutralised, treated with hydrogen sulphide, and titrated as described above for the actual determination of zinc. The end point is more distinct if the ferrous sulphate is added about 0.5 c.c. before the finish.

One, or at the most two drops of sodium bicarbonate solution cause a distinct darkening that is not materially increased by the addition of a further cubic centimetre.

In carrying out the determination of zinc by this method, the following points must be noted:—

(A) Copper, lead, and bismuth, unless present only in traces, must be removed by means of iron gauze or hydrogen sulphide in acid solution.

(B) Iron should be present in the ferrous state, otherwise the neutral point is obscured. Heating with iron wire or sulphurous acid speedily accomplishes this.

(C) The volume of solution should be about 150 c.c. after adding hydrogen sulphide water, when the zinc is 0.1–0.3 gm. If the zinc is present in small quantity, say 0.1 gm., a sharper end reaction is given if the volume does not exceed 70 or 80 c.c.

(D) As in the case of most zinc titrations, the conditions should be as near alike as possible in sample and check test.

Although designed primarily for the rapid determination of zinc in ferrous liquors, the method is capable of wider application if the prescribed conditions are adhered to. Unlike most well-known methods, iron and manganese are not detrimental: in fact, the former is necessary.

The following experiments were made to show the effect of various metals on the zinc assay:

Weight of zinc taken.	Iron.	Manganese.	Cobalt.	Nickel.	Aluminium.	Zinc found.
grms.	grms.	grms.	grms.	grms.	grms.	grms.
0.25	0.02*	—	—	—	—	0.2498
0.25	0.50	0.1	—	—	—	0.2464
0.25	0.02	0.1	—	—	—	0.2504
0.15	0.02	—	—	—	—	0.1504
0.15	0.02*	—	—	—	—	0.1496
0.15	0.02	0.15	—	—	—	0.1496
0.15	0.02*	—	0.015	—	—	0.1500
						0.1472
0.15	0.02	0.15	0.15	—	—	0.1516
0.15	0.02	0.15	—	0.015	—	0.1510
0.10	0.10	—	—	—	—	0.0956
0.10	1.00	0.10	—	—	—	1.000
0.10	0.10	0.10	—	—	—	1.004
0.10	0.02	—	—	—	0.02	0.1020
0.01	0.01	—	—	—	—	0.0104

It will be seen from the above that the amount of iron has very little effect on the result. Cobalt, nickel, and aluminium, if not more than 5 per cent. to 10 per cent. of the zinc present, do not interfere. Manganese has a beneficial influence, causing the end point to be more distinct.

In the absence of metals of the second group and ferric salts, the whole operation can be completed in 5 or 6 minutes.

If desired, the chocolate coloured precipitate, consisting of the whole of the zinc as sulphide, together with a small amount of ferrous sulphide, may be filtered off; and after washing with water to remove manganese, cobalt, nickel, and iron, dissolved in hydrochloric acid followed by bromine. One precipitation with ammonia will suffice to separate the whole of the zinc present. A rapid means is thus afforded of obtaining a pure zinc solution, on which a check analysis may be made by some other method.

These experiments were carried out in the central Laboratory of the United Alkali Co., Ltd. I am indebted to the courtesy of Dr. Raschen and the directors of the company for permission to publish these results.

DISCUSSION.

Mr. E. CAREY asked what the author considered the limit of error in the assays. The results were very interesting, but he felt a little disappointed at the want of definiteness with regard to the point at which the indicator would show black; it was evidently a test which required a considerable amount of practice.

Prof. F. G. DONNAN asked if the concentration of iron was likely to produce an error. Example No. 2 in the table, which showed a considerable error, gave the iron as present in large excess.

Mr. TAYLOR in reply, said he could not give examples of the limit of accuracy other than those in the table, which were the results of experiments on known amounts of zinc. The probable error would be about 1 per cent. of the zinc present, but with practice, should be much less. He could not explain why in one case where the iron was twice that of the zinc, the zinc found was 0.2464 gm. instead of 0.25 gm.; in one case the zinc found by titration was exactly the amount introduced, though the amount of iron present was 10 times that of the zinc.

* In these experiments the ferrous sulphate was added near the end of the titration.

DR. J. LEWKOWITZ IN THE CHAIR.

THE MANUFACTURE OF ARTIFICIAL STONE FROM SAND AND LIME.

BY J. C. STEAD.

The manufacture of artificial stone blocks from mixtures of sand and lime has been carried on for some years with more or less success, but little appears to have been published as to the results of actual work, although German and American literature referring to silica and sand-lime bricks is fairly plentiful.

With slaked lime, bricks and also satisfactory blocks of artificial stone which have upwards of 25 cubic feet content are produced. For either brick or stone the proportion of lime used varies from 4 to 10 per cent., and both, when finished, are usually capable of sustaining fairly high compressive loads.

The stone with which this paper deals was made of a mixture of sand and quick lime filled into moulds, subjected to the action of steam or hot water under a pressure gradually raised to, and maintained at, 9 to 10 atmospheres, then cooled, removed from the moulds, and used without further treatment. However, although it is possible thus to make perfect blocks of, say, 6 feet in diameter and 3 feet deep, yet so far there have been considerable difficulties as to uniformity of output.

When working with plain moulds, with a mixture containing from 12 to 14 per cent. of lime, the finished blocks were found to contain globular masses of stone quite distinct from the exterior cylindrical shell. The division between the two coincided apparently with the points or lines where the pressures developed by the resistance of the mould to the expansion of its contents (due to the slaking of the lime) were equalised, and became uniform. This necessitated some modification of the rigid mould employed, and in the next and all succeeding experiments a cushion of sand surrounding the whole of the mixture contained in the mould was introduced in order to neutralise these pressures to a certain extent. The globular formation within the stones then ceased to be produced. The sand layer or cushion appeared also to have a further advantage, in that it assisted the diffusion of the water or steam throughout the mass of the stone mixture, besides facilitating the removal of the stone from the mould at the completion of the process and cooling.

With a mixture containing 13 to 14 per cent. of lime, stone as that marked S3 in the table resulted. This was very hard, and although excellent in all other respects, was rather too dense for ordinary building purposes.

In the next series 10 per cent. of lime was used, the other conditions remaining the same. The stone from this was cracked at right angles to its greatest dimension, and was evidently of insufficient strength to withstand the stresses set up within its mass.

A return to 13 to 14 per cent. of lime gave unsatisfactory results with blocks 3 feet deep, owing apparently to dusty sand being used. The penetration of the water into the mass of the contents of the mould was in many instances bad, portions of the blocks were not thoroughly hardened, and the stone formation was incomplete. Cracks encircled and crossed the imperfect parts and also radiated therefrom; but in those portions which were well penetrated by water the stone was of good quality, free from flaws when cut up, and generally remained so when exposed in the yard.

On diminishing the vertical thickness, stones up to 2 ft. thick showed no flaws, and their texture was uniform throughout, the water having evidently diffused equally

and quickly in all directions. These last blocks were made at a time when the temperature varied considerably. The slabs into which the blocks were cut, soon developed cracks at right angles to their greatest dimensions, but not extending to the circumference. Sound slabs of stone made during the summer months did not so crack, although exposed in the yard immediately after sawing onwards and also during the winter months to alternating damp and frosty weather. The winter-made blocks, which were of good uniform hardness when cut, when exposed, laid flat, just as natural stone would lie upon its bed, became softer and ultimately cracked up in all directions. The porosity of the newly made stone obviously favoured the absorption of moisture from mist and rain which, alternating with hard frosts, had the usual disintegrating effect.

All of the series were made with sand containing 98.3 per cent. of silica, and quicklime titrating upon an average 92.4 per cent. of calcium oxide.

The general characteristics of typical specimens of the stone produced are given in the accompanying table.

The first six of the following are samples of the stone referred to in the foregoing:—

Number of mark on block.	When made.	Per cent. of CaO in mixture used as per titration.	Appearance of the stone produced.	Porosity 20/5/09. The numbers rising as the porosity increases.	Load on bed under which stone failed, lbs. per sq. in. The tests were made with 3-in. cubes rubbed dead true.	Remarks.
S 3.....	Oct., 1907	13.4	Very close and fine; arrises sharp and good.	1	9,485	Full sized block = 6 ft. diam. by 3 ft. 6 in. deep approximately. Stone excellent throughout.
S VIII.....	May, 1908	11.0	Somewhat coarse; arrises not sharp.	7	1,038	Full sized block. Stone uniform throughout. Cracked vertically.
S XIV.....	June, 1908	17.2	Close; arrises good.	2	8,879	Full sized block. Penetration of water imperfect; block contained patches of badly formed stone.
S XXX.....	Aug., 1908	14.0	Close; arrises good.	3	5,535	As S XIV.; in this case central portion badly formed.
S XXX.....	Aug., 1908	15.7	Close; arrises good.	4	6,24	Full sized block; had but few faults; was generally good.
SL VIII.....	Dec., 1908	14.27	Close; arrises good.	8	4,683	Block of diminished depth; well penetrated by water, and stone good.
E.....	Prior to July, 1907	6.8	Somewhat coarse; arrises not good.	6	4,815	
III. (made with slaked lime)	April, 1908	9.3	Somewhat coarse; arrises not good.	5	3,612	

The figures as to porosity and resistance to crushing are not comparative, the specimens not being of uniform age. They, however, show the effect of different proportions of lime and of varying age.

The results obtained indicate at least four considerations which require to be constantly borne in mind. They are:—

(1) The proportion of lime used must be such that the resulting stone be sufficiently strong to withstand the stresses set up.

(2) The whole of the mass of the dry mixture contained in the mould *in situ* in the hardening cylinder must at the commencement of the process be thoroughly and as nearly as possible simultaneously saturated with steam or water.

(3) The contents of the mould must not be subjected to excessive pressure.

(4) The stone, particularly when made during a season of low temperatures and variable climatic conditions, requires some period for maturing and that preferably in a suitable atmosphere, e.g., one containing carbon dioxide, for the purpose of diminishing its porosity before use.

The first two conditions are not obtained without considerable attention to detail. A mixture of sand and lime containing, say, 10 per cent. of lime is easily and quickly

permeable to water, but the resulting stone lacks strength and is liable to crack during or immediately after formation. A mixture titrating 13 to 14 per cent. of lime yields stone which is strong enough, but which may be cracked owing to the unequal and imperfect penetration of the water or steam. It would seem that this is not solely due to the increase in the proportion of lime *per se*; but in part to the silica dust contained in the sand. The fine particles favour a more intense reaction with the increased lime, which is to a certain extent cumulative and tends to seal off portions of the block. These are not necessarily the central portions, since the imperfect stone due to bad water or steam penetration is sometimes found to be annular or horse-shoe shaped, the centre of the block being hard and perfect. If the sand be very dusty or dirty it may of itself impede or stop the diffusion of water or steam. Sound stone can be produced by the means indicated from a mixture containing a certain percentage of lime, and ordinarily uniform procedure with uniform temperate climatic conditions produces uniform results.

I am indebted to the directors of Ford Stone, Limited, for their kind permission to publish the foregoing notes,

DISCUSSION.

Mr. W. F. REID said he did not like to criticise this paper in the absence of the author and would only remark that he seemed to think that pressure and high temperature were unsuitable for producing this stone, but it was a well-known fact that sand lime-stone was made successfully in large quantities under such conditions. It was stated that the temperature must be raised simultaneously throughout the mass; and other conditions were laid down without any indication of how they were to be fulfilled.

Mr. WATSON SMITH referred to the extraordinary results obtained by Messrs. Parr, Ernest and Williams in the United States, in the use of finely divided silica mixed with lime (see this J., 1909, 1131). They stated that by the high-pressure steaming of briquettes (150 lb. per sq. in.) made by moulding 80 per cent. of finely divided silica with 20 per cent. of lime, blocks were obtained which had a tensile strength of 278 lb. to the sq. in. These on subsequent heating to various degrees, showed great and singular variations. Thus heated to:—

400° C.	a tensile strength of	0 lb. per sq. in. (i.e., a fall to zero)
600° C.	" "	131 " " " "
750° C.	" "	27 " " " "
800° C.	" "	71 " " " "
1330° C.	" "	263 " " " "

Large rise, but not as high as strength at 20° C.

Meeting held at Burlington House on Monday, December 6th, 1909.

DR. J. LEWKOWITZ IN THE CHAIR.

THE ARTIFICIAL SILK INDUSTRY.

BY W. P. DREAPER, F.R.C.

In the French Exhibition of 1889 Count de Chardonnet exhibited his now well-known process of manufacturing filaments of nitrocellulose by squirting collodion under suitable conditions into the air. The progress from this early production of highly inflammable filaments, to the present production of the large output of artificial silk manufactured by this process, which exhibits none of these inflammable properties, and resists the disintegrating action of water has been achieved by careful research. To-day the production of the material by the original method, starting with a solution of gun-cotton, has met with signal success; and even in the absence of any competing process would have led to the building up an industry of a permanent nature, from which the textile industry generally would have derived much benefit. This process of manufacture may in time go the way of most original processes, and give way to the more direct methods of later date. At present it is responsible for about 50 per cent. of the world's output. I have been informed in the Elberfeld-Barmen district, where 500,000 kilos. are worked up every year, that for some manufacturers the nitro-product is absolutely essential, while for others the newer products are of more value. If time proves that this is a normal condition, then the mere cost of production will not be the only determining factor in the situation.

Any way it is patent to all those interested that great economies have been effected in this process, more especially in the recovery of the solvents, and their re-use; in the rapidity of production; and in other ways of which no one outside the actual works can have definite knowledge.

Of the processes which have survived to this industrial stage, the three systems called, respectively, the nitro-cellulose, the cuprammonium, and the viscose ones may be specially mentioned. These have been so controlled, that they now produce a marketable product, which is in such demand that delivery can only be obtained for the second half of next year at the earliest. This latter point is an important one, for it is an indication that the newly-founded industry is based on a genuine demand.

These yarns, which range in size from 100 deniers upwards, are not adapted to the manufacture of such materials as are prepared from ordinary silk fibres of from 15 to 32 deniers, or even upwards; but they enter into a whole range of articles, and have had a profound influence on certain manufacturers, such as the braid industry, and given employment to a large number of hands. The new uses which are being found almost daily for these products also indicate a steady and increasing demand for the yarns in the future. For example, it is possible to manufacture a heavy cloth from these high denier yarns.

The early samples of the nitrocellulose product were extremely brittle and inflammable, and lost 50–70 per cent. of their strength on wetting. They were, however, extremely brilliant, and this satisfactory factor certainly led to further research and improvements in other directions, which gradually decreasing these objectionable features, caused such a demand for the yarn in comparison to the possible supply, that the price of this artificial silk for a time actually exceeded that of the real material. The extreme brightness of the goods made from it, and their peculiar feel, was undoubtedly the cause of this. With this state of affairs there is no wonder that the industry in France and Germany expanded, and several companies were undoubtedly formed to work processes which had little chance of commercial prosperity. The patent list of these times also indicated the gradual expansion of the experimental work which naturally followed, and was destined to give to these countries an absolute monopoly of manufacturing, which they have

held to all purpose until the last year or so; and also to give to the textile manufacturers of these countries a first call on this important and novel product. The absence of the yarn itself in this country, was one of the chief factors causing our neglect of this matter. The many difficulties of the process were emphasised by the failure of the English Company (starting to manufacture under the Chardonnet rights) due, it was then said, to local atmospheric conditions, the actual solution prepared in France refusing to spin at the Coventry factory.

Dr. Lehner demonstrated his process in London, but it was in Switzerland that he built up the enormous business which is associated with his name, and which to-day turns out such large quantities of the nitro-product. Chardonnet had to work with very high pressures, but Lehner, by modification of the solution, was able to squirt at very low ones. He also squirted into water, and in this way recovered the major portion of the solvent. The threads of nitro-cellulose were wound on to bobbins and dried.

Factories producing such a product were destined, sooner or later, to come under the notice of the insurance companies. Serious fires took place, and were unpreventable. It was found that the nitro-cellulose yarn in the dry state, like silk, became highly charged with electricity, and that self-ignition took place. The risks were subsequently modified by keeping the yarn in a wet state until it entered the "denitrifying" bath. There was still the alcohol-ether to be reckoned with, and it is, I believe, still impossible to insure such a factory. This mattered little, however, to companies making such profits. The Tubize Company rebuilt part of its factory a few years ago out of the year's income and still paid a good dividend.

Great speculation in shares; high and fluctuating prices for the yarn; fire at the works—but, most important of all, an increasing demand for the product, characterised the early days of the industry, the slow and steady progress of which was assured and never in doubt.

HISTORY OF THE INDUSTRY.

In 1845 the well-known French investigator Reaumur suggested the production of what might be termed artificial silk, and in 1885 Audemars patented the production from a nitro-cellulose base, but nothing more was heard of the process. In 1884 Count de Chardonnet deposited with the Académie des Sciences a sealed document which was opened on November 7, 1887; it bore the title "Sur une matière textile artificielle ressemblant à la soie." He had sufficiently worked out his process of manufacture to obtain a Grand Prix at the Paris Exhibition of 1889 for his product. He lodged his first patent on November 17, 1884 (Fr. Pat. 165,349). The first apparatus actually used for trials is shown in a photograph published in a work published by T. Foltz in 1903 (*Fabrication de la soie artificielle parisienne*).

In 1889 Dr. Vivier produced a product termed "Soie de France," but except in small details the production, and product, was very similar to that of Chardonnet. In 1892 Lehner patented his modification of the Chardonnet process (Fr. Pat. 221,991, May 25, 1892).

As a result of these early inventions the following centres have produced this nitrocellulose product in large quantities. Works at Besançon, in France; at Tubize and Droogenbosch-Ruysbroeck, in Belgium; at the four factories of the Vereinigte Kunstseide Fabriken, of Frankfurt; at Kelsterbach S.M., at Robinson near Augsburg; Glatbrugg and Spreitenbach, near Zurich; at Padua in Italy, and in Hungary.

The first patent connected with the production of artificial silk from cellulose dissolved in a cupro-ammonia solution was that of Despeissis (Fr. Pat. 203,741, Feb. 12, 1899). The only remaining record of this appears in a French publication, as under the French law of that date the specification was not printed, and being abandoned, owing, I believe, to the untimely death of this investigator, is not available for reference. Nothing more was heard of this process until Pauly in 1897 patented a process on very similar lines. The English specification has since been restricted by amendment so that the original suggestion of Despeissis, viz., the addition of a proportion of

some albuminoid substance to the solution, has been omitted in the latter specification. In 1899 (Eng. Pat. 6556, 1899), Fremery and Urban took out their first patent, dealing with details in the manufacture. In the same year (Eng. Pat. 18,260, 1899), Brounert patented his first improvement in connection with the direct solution of cellulose, although he had previously, in 1886 (Eng. Pat. 6858) taken out a patent for improvements connected with the nitrocellulose process.

Pauly, Brounert, Fremery, and Urban are for ever associated with the industrial application of the copper-ammonia process on the large scale: they have through their investigations led to the development of the celebrated Glanzstoff Company, which to-day employs over 7,000 hands, and manufactures such large quantities of this product. Their headquarters are at Elberfeld, and works at Niedermorschweiler and Oberbrück in Germany, and they are also interested in works at Givet, and at Izieux, in France (Messrs. Gillet et Fils). I believe that a Spanish Company, the Socio-lad Espanola de seda Parisien, has ceased working. The British Glanzstoff Co., Ltd., has recently started works at Flint, which it is said will give ultimately employment to 2,000 hands. It is understood also that works will shortly be erected in Russia.

In 1902 Thiele took out his first patent for improvements which enabled much finer filaments to be spun than heretofore. This and subsequent patents suggested a possible development in the industry (Fr. Pat. 320,446) in competition with the natural article.

Since that date the patents registered in connection with this copper-ammonia process have been very numerous. Only time will demonstrate their respective merits. In some cases copper carbonate in ammonia is used to dissolve the cellulose. Many patents deal with the use of different precipitating solutions, and details in the process, such as, for instance, the preliminary mercerising of the cotton.

In the early days there were in this country several investigators of note working on the subject of artificial filaments, amongst whom may be mentioned Crookes, Swinburne, Wynne and Powell, and Swan; also the first patent for a direct process of manufacturing from allulose was taken out by two Englishmen in 1884. It was not until six years after this date that Despeissis took out his first patent, which formed the basis for the early working of the cuprammonium process. It remained for France and Germany to bring this industry to a successful issue. However, having recently reached a state of manufacturing efficiency, as at the Coventry Viscose Works, we have made up for lost time.

It was natural that France, with the silkworm industry so firmly established in the south, should look with greater interest upon the possible manufacture of an artificial product, which might supplement the natural supply. The fact that Pasteur was instrumental in saving that industry from decay may also have had an influence in intensifying the belief that the problem was capable of commercial realisation through the aid of scientific research.

PROCESSES OF MANUFACTURE.

Charbonnat Process.—The original plant at Besançon started with an output of 50 kilos, a day in 1891; it had reached 1500 kilos, in 1904, and 1800 to 2000 kilos, in 1907, and seems to remain at that figure in 1909. The breaking-strain is given at 1.5 grm. per denier, and the elasticity at about 15 per cent. Whether elasticity is quite the term to use in the case of artificial silk is perhaps open to question. It is doubtful if the "stretching before breaking" which takes place can be compared with the actual elasticity of the real fibre.

Great precautions are necessary in the production of the solution or gun-cotton. The polariscope is used in determining the correct state of solution. The jets through which the colloid is squirted are accurately regulated by micrometric measurement. The process of denitration is, of course, a reducing one, and the details remain a secret. Temperature of the bath is a consideration, and the great aim is to reduce the loss of strength to a minimum.

Years of study have greatly improved this operation, and have produced a thread which varies very little in this respect from day to day.

The statement is made that in 1907 2,500,000 litres of alcohol were consumed in the Besançon works, so that each kilo. required between 4—5 litres of alcohol in its manufacture. A kilo. of 100 denier thread of this silk contains 90,000 metres in length, or nearly 2 millions metres of single filament as squirted from the jets. The selling price of this product has been given as 30 fr. per kilo. in 1896, 26.50 fr. in 1897, and 21.75 fr. in 1898; in 1903 it reached the price of 10 fr. per kilo., and it may be taken at 20 fr. to-day.

Zinc chloride process.—The first patented invention dealing with the production of artificial filaments by the direct solution of cellulose in aqueous solution and without the intervention of the nitrating process was made by Wynne and Powell in 1881 (Eng. Pat. 16,805 of 1884). These investigators seem to have confined their attention to the industrial production of electric light filaments, and this process has proved itself of great value in this direction and is in use to-day.

In conjunction with H. K. Tompkins, I took out further patents in 1897 dealing with details. In one of these patents the advantage obtained by "drying of the fibres or threads in a considerably stretched condition" was emphasised. This practice has since found a place in all the artificial silk processes dealing with the direct solution of cellulose which have since reached the industrial stage; and without it, it is impossible to obtain yarns of the maximum brilliancy.

Brounert in 1899 patented the preliminary mercerising of the cellulose and claimed that the solution was correspondingly facilitated. A good deal of work was done in this country by the Cellulose Silk Syndicate, Ltd., in connection with this process, and also by Brounert on the Continent; but in spite of statements to the contrary, I do not think that this process has ever been worked on a very large scale.

The cupro-ammonium method.—As before mentioned, this originated with the Despeissis patent (Fr. Pat. 203,741, Feb. 12th, 1890). Nothing was, however, done with the process until Pauly re-patented the process in 1897 (Eng. Pat. 28,631 of 1897). The cellulose is dissolved in an ammoniacal solution of a copper salt. The details of this method are, of course, not made public, but after filtering a satisfactory solution may be obtained. The coagulating solution may be a 15 per cent. solution of sulphuric acid, copper sulphate and ammonium sulphate being produced, and the cellulose is precipitated in the thread form, and wound on suitable winders, which are usually made of glass. The newly-formed fibre is then washed on these holders with fresh water.

E. Brounert (Eng. Pat. 18,884 of 1899) claims the treatment of cellulose with caustic soda, and then copper sulphate is added. When ammonia is added to the resulting mixture of cupric hydrate cellulose and sodium sulphate, a solution of the cellulose is obtained. Many patents have since been taken out, and it is obviously impossible to disclose the exact procedure in any works, even if they are known.

The recovery of the solvent materials is mentioned later. Fremery, and Urban have observed (Eng. Pat. 20,630 of 1899), that it is advisable to dry the product in two stages: first at 104° F., and afterwards at a higher temperature. If the yarn be submerged in water at a temperature of 158° to 212° F. they claim that a dehydrating action takes place with beneficial results.

Viscose Process.—In the year 1892, Cross, Bevan, and Beadle (Eng. Pat. 8700 of 1892) patented their method of bringing cellulose into solution for industrial purposes, but it was not until 1903 that Stearn (Eng. Pat. 1,020 of 1898), disclosed a commercial method of preparing filaments by precipitating this solution in the required manner by means of a solution of ammonium salts. This process was found to offer special difficulties, but to-day they have been overcome; and as a result of the initial work and first experiments at Kew, works have been erected at Coventry by Messrs. Samuel Courtauld and Co., Ltd., where this product is being produced in

increasing quantity. The process is also being worked at Sydowsauc, near Stettin, in Germany (Kunstseide und Acetatwerke Fürst Henckell Donnersmærk), in France, at Arc-la-Bataille, near Dieppe (Société Française de la Viscose), and in Italy.

Further important work has been done in this country on this process by Courtauld and Wilson (Eng. Pat. No. 21,405 of 1907), who suggested the addition of glucose to the precipitating bath, and Topham (Eng. Pat. 23,158 of 1900) who applied the turbine method of collecting the threads to these artificial fibres, an extension, I believe, of its previous use in the spinning of very short-fibred yarns, such as asbestos. Many patents have been taken out by other investigators, which deal with the preparation of the solution, methods of squirting, and subsequent treatment of the yarn, but they are too numerous to mention here. It is interesting to note in passing that the jets used for squirting in this process are made of platinum.

An extension has been granted to the original inventors for their patent rights in this country, so that although the patent dates from the year 1892 the rights are still in operation.

Cellulo silk process.—This product is manufactured under the Thiele patents at the English works at Great Yarmouth. Yarn is being produced down to 35 denier, or even lower. The process is a modified copper-ammonia one but there are many secret details connected with the manufacture. In spite of the relative fineness of the yarn, the number of filaments is greatly in excess of other makes which are on the market at the present time.

Cellulose acetate process.—Several patents have been taken out in this direction, notably by the Bayer Co., the Badische Co., and the Donnersmærk Co. They chiefly deal with the control of the methods of preparing the cellulose acetate. The question of a suitable solvent seems to present a great difficulty, although it is stated that there are many derived acetates, and that some of these are soluble in alcohol, or pyridine; but chloroform seems to be the chief solvent. Quite recently (Eng. Pat. 6654 of 1909), it has been claimed that formic acid is a satisfactory solvent. If this is so, a distinct advance has been made.

Gelatin and Casein Processes.—Very little has been done in this direction from the commercial point of view. In 1897 Millar patented a gelatin process (Eng. Pat. 2,713 of 1897); in 1907 Mugnier used vegetable albumins with the addition of borax, and Jannin patented the use of a solution of gelatin, glycerin, and formaldehyde in 1904 (Fr. Pat. 342,112). Casein was used by Chatelineau and Fleury, Timpe, and Todtenhaupt, but little has been heard of these processes.

Recovery of solvents.—The recovery of raw materials used as solvents is an important step in the nitrocellulose and copper-ammonia processes. It is, so far as I know, of small importance in the manufacture of viscose silk. In the first case, the recovery of alcohol, ether, or acetone from the air is important from the cost point of view, but is a difficult operation. Exactly what proportion is recovered in practice has not been disclosed.

Quite recently the Tubize Company have patented the absorption of the alcohol and ether vapour in sulphuric acid of 62° B. at 20° C.

In the copper-ammonia process both the copper and the ammonia can be recovered by known means. When the precipitating liquid is of an acid nature, electrolytic methods are available for the removal of the copper, leaving the ammonia behind in solution. This solution may be used for manuring purposes, or the copper may be precipitated as sulphide.

Recently applications of the known reducing action of glucose has been brought forward in the case where the precipitating solution is of an alkaline or caustic nature. The addition of glucose to the precipitating bath throws the copper out of solution almost immediately, and the precipitating solution has a much longer life. This process works well in practice.

These few remarks will indicate some of the methods

adopted in different cases, dealing with this important branch of the manufacture.

Machinery.—Each process has its special requirements as regards the machinery employed, and these have been naturally met in various ways. Companies working the same process in different countries differ materially in actual methods. In addition to this there is a mass of detail, which in many cases is not protected in any other way than that of secret working, and may be confined to the working of a single factory. Under these conditions I can only indicate one or two cases which may illustrate the methods adopted in the manufacture of these threads.

The first case is that of the original Chardonnet apparatus. This is of interest as showing in the original patent (Eng. Pat. 2211 of 1886) the amount of detail already available in those early days. The thread passed from the jet, which had a bore of 1/20 to 1/5th in., through a very short column of water and then on to the winder. When a thread broke, the broken end was seized by pincers and carried over guides to the reel to be wound. The pinions still ascending are cleaned by a rapidly revolving brush, before they descend again to pick up any more broken ends. This movement is repeated several times a minute. Air heated to 85° to 90° F. is passed by supply and discharge conduits through the outer chamber. The vapours carried by the air might be "condensed and removed by cooling" and the air after warming returned to the apparatus. The so-called Topham turbine system of collecting and spinning the threads at the same time (Eng. Pat. 23,158 of 1900) is a good illustration of the methods adopted to overcome the difficulties in manufacture. The squirted thread passes over a roller and thence into a rapidly rotating box. The fibres or threads as they are fed in are twisted together and are caused by the centrifugal force to form a compact coil around the interior of the box and to be formed into hanks or skeins. If the boxes are deep, a longitudinal reciprocating movement can be given to either the box or the funnel to make sure of the even coiling of the thread in the skein form. I have seen this apparatus at work on the Continent, and it certainly illustrates a very ingenious method of combining the skiving and twisting in one operation. It is, or has been largely used in the manufacture of artificial silk. It reduces the strain on the newly formed threads to a minimum.

A third example is that of one of the more recent patents dealing with modifications in the Thiele "two-solution" process of spinning. (Dreaper, Eng. Pat. 21,872 of 1908; see this J., 1909, 1246.) In this case arrangements are made so that the freshly squirted thread comes in contact with a precipitating solution which acts comparatively slowly, and then passes into a stronger one.

PROPERTIES OF THE FIBRES.

Recognition of artificial silk yarns.—The nearer these yarns approach real silk in their physical properties, the more important will it become to have a satisfactory method for distinguishing between them. The qualitative and quantitative estimation of these different fibres has been studied by Saget and Süvern (Bull. Soc. d'Encouragement, 1906, 540), in comparison with real silk.

The ash in these products is under 2 per cent. Natural silk contains 17 per cent. of nitrogen as compared with the following figures for artificial silk:

Nature of Yarn.	Per cent.
Pauly make (Cuprammonium)	13
Chardonnet (Nitrocellulose) French	15
do, do, German	16
Lehnert do,	17
Nitrocellulose	9.15 to 14.14

It must therefore be the different state rather than the amount, in which the nitrogen is present in the (reduced) nitrocellulose products which determines its effect in dyeing with basic dyes, if this is the real cause of this phenomenon.

Diphenylamine sulphate is the ready test for artificial silk, and give the following reactions:

Silk	Brown colouration.
Tussah silk	do. (intense).
Chardonnet and Lehner (Nitrocellulose) ..	Intense blue.
Pauly, Viscose or Yarmouth silks	No reaction.

Strength on wetting.—This loss in strength has introduced a serious factor into the manufacture of textiles, but under present conditions this defect is gradually decreasing, and may in time be eliminated. This is seen by comparing figures published in 1900–1901 with more recent figures which are available.

In the year 1900 an isolated test (Bronnert, Bull. Soc. Ind. Mulhouse, 1900) gave a loss of 77 per cent. for Chardonnet silk in strength on wetting.

In the year 1901 Strehlenert gave the following figures:—

Yarn.	Dry strength.	Wet strength.	Loss per cent.
China silk	53.2	46.7	14.1
French (ecrue)	50.4	40.9	18.8
Chardonnet silk	14.7	1.7	89.6
Lehner	17.1	4.3	74.8
Viscose (old)	11.4	3.5	70.0
Do. (new)	21.5	3.5	84.0
Glanzstoff	19.1	3.2	83.0

These figures give an average loss of 82.8 per cent. on wetting for the artificial products.

In 1903 Hassack gave the figures, from which the strength per denier has been calculated, as follows:

Quality.	Denier.	Breaking strain in grms.	Do. per denier in grms.	Elasticity, per cent.
Genuine silk	23	57.5	2.5	21.8
Chardonnet silk* ..	80	74.2	0.93	8.0
Fismis*	100	71.7	0.71	11.6
Walston*	120	151.4	1.26	7.9
Lehner*	120	171.8	1.43	7.5
Pauly	120	197.6	1.64	12.5
Gelatine	100	63.0	0.63	3.8

* Nitrocellulose products.

Recent figures given by the testing department of the Manchester Chamber of Commerce show the following results:—

Yarn.	Dry strength.	Wet strength.	Loss per cent.
Glanzstoff	92.5	31	66
Cellulo silk	75.5	33	56

According to these figures the Glanzstoff product now loses 17 per cent. less "on wetting" than in 1901. The Cellulo Silk product loses still less. The present-day strength (dry) is given by Cross and Bevan at 1.0–1.4 grms. per denier, against 2.0–2.5 grms. for real silk. I think this figure should now be extended to 1.6 grms. for the artificial silk product. The "extensibility under breaking strain" at 13 per cent. to 17 per cent. for the artificial product against 15–25 per cent. for real silk. The average loss in strength on wetting is given at 70 per cent. for all varieties (Escalier).

I have recently received a sample of a 25 denier artificial thread containing 60 filaments, which has a breaking strain of 58.5 grms. This shows a breaking strain of 2.3 grms. per denier. This is quite as strong as some natural silks. A pound of this silk would contain 176,000 yards, which would contain 10,560,000 yards of filaments, or six times the length which a corresponding weight of natural silk of the same size would contain.

Strength factor and size of threads.—The following figures indicate for the same make of silk an important increase in strength for the finer sizes per unit weight of

thread (denier) and with it a decrease in "elongation before breaking." This latter figure does not mean that the elasticity is less. The fact that the number of filaments remains constant for the sizes tested is probably the cause of this phenomenon. They were as nearly as possible made under standard conditions, and from the same solution of cotton. The results are shown in the curve from the actual figures obtained.

Dyeing properties.—No two makes of artificial silk dye in exactly the same way. All the makes on the market dye with the direct, or cotton dyes, as might be expected. The general procedure is to dye at a low temperature, but I have seen artificial silk in mixtures dyed at the ordinary temperature for silk, after a "boiling off" in 1 per cent. soap solution for 1½ hours. Ingrain colours do not seem to give fast results on this product; the reason for this is unknown. Difficulties have been experienced in dyeing some dark shades satisfactorily in the past, but these have been overcome.

The cellulose acetate product stands alone in its dyeing properties; it is stated that a dye-bath containing alcohol greatly facilitates this operation.

The nitro-product is not capable of standing the "Lancashire bleach," but samples of cellulo silk have stood it fairly well. Real silk would go into solution under the treatment.

Waterproofing.—The lack of strength in the finished yarn in the wet state has as mentioned been a source of great complaint in the past. Great improvements have taken place in this respect and there are indications that with time this defect may be altogether overcome. Naturally all manufacturers have been engaged in the problem of preventing this degradation of the fibre when wet, due to the hydration of the reprecipitated cellulose. No known process of waterproofing by the application of waterproof materials in a suitable solvent is applicable, or of any real value. An attempt on altogether different lines has been made by Escalier (Monit. Scient., 1908, 13, and patents), who claims that he brings about a condensation of the cellulose molecule by treatment with formaldehyde. The recently published results of the strength of yarn in the dry and wet state, certainly indicates a specific action, and that this treatment reduces the tendency for the thread substance to return to the jelly state in the presence of water.

Some years ago the application of formaldehyde for this purpose was patented by Strehlenert (Eng. Pat. 22,540 of 1896) but it was only claimed for nitrocellulose products and was applied to the solution of that substance before squirting.

The only alternative to some such process seems under present conditions to be the use of a raw material which will not hydrate in the presence of water. This material is undoubtedly present in acetylcellulose, and if the working of this material becomes amenable to commercial conditions, any special treatment will be unnecessary. However, cellulose acetate is so waterproof that it will not absorb dyes from aqueous solution. Silk itself has the advantage of not losing its strength in the wet state, yet it is easily dyed.

The loss in strength on wetting is a temporary defect. It is entirely regained on drying. For example, fabrics of artificial silk and silk in mixture were boiled in 1 per cent. soap solution for 1½ hours in order to discharge the silk gum from the silk. They have suffered little, if any deterioration from that process. Care is needed in the handling in the wet state, but it is not beyond the scope of modern dyeing and finishing to meet the necessary conditions, even with very fine counts.

Any further small reductions in the loss on wetting will materially decrease the difference which exists to-day between the relative strength of these yarns and silk, and bring nearer the time when they may be equal in this, and other respects.

Scroup.—The peculiar rustle which silk possesses when dried out of solution of acid is imitated when these artificial fibres are treated in the same manner. So that in this respect the behaviour of the two fibres is identical. This fact may, on investigation, give some more definite explanation as to the cause of this phenomenon.

The brilliancy of the fibre in the coarse counts is greater than that of real silk. In the processes dealing with the production of these yarns directly from cellulose, the chief factor in obtaining this is the method of stretching the yarn during drying. The nitrocellulose product, if properly denitrated, is very brilliant, owing to the surface condition of the fibres and as in other makes the continuous nature of the filaments.

Size of individual filaments.—The 120-denier thread of to-day varies in the number of the individual filaments, but it may be said not to exceed 25 in number; so that the size of the individual filament may be taken at from 5 to 8 denier. Actual silk averages 2.75 denier per filament. The fine denier Cellulose silk (30 to 50 denier) may contain 45 to 60 filaments, so that here the size is about 0.5 to 1.1 denier. The fineness of real silk has been exceeded in this case. In the sample produced of a 15 denier artificial silk thread (Yarmouth make), the individual filaments are 0.33 denier, or roughly 1/8th of the size of those of real silk. This is the first time that such a thread has been exhibited.

WORLD'S OUTPUT OF ARTIFICIAL SILK.

This has been recently given at about 3,000,000 kilos per annum at the present rate of production, against 1,700,000 kilos in 1906, and 600,000 kilos. in 1896. These figures indicate an increase of 500 per cent. in 13 years.

The nitrocellulose product still heads the list with an output of between 1,300,000 and 1,600,000 kilos. The "copper-ammonia" process accounts for 1,100,000 to 1,300,000 kilos. The production of Viscose silk now amounts to 500,000 kilos.

These figures are large, but that will be greatly exceeded in the future. Within three years the viscose production may be doubled, as it is the intention to establish large works in America and elsewhere.

Output of natural silk.—The total returns for 1908 of the 24 European conditioning houses amounted to 51,445,000 lb. These figures show an increase of 30 per cent. in a decade (the average for the years 1896-8 being 34,929,400 lb.) to which all the three great producing centres, viz., Europe, the Levant, and the Far East, have contributed. It is, however, significant that the increase in Europe is only 20 per cent., against 50 per cent. for the Far East, and 100 per cent. for Asia Minor. This last increase is said to be entirely due to the efforts of the Silk Institute at Broussa; and the consequent introduction of scientific methods. In France the production of cocoons has not increased during the last years, in spite of large sums paid in State bounties, amounting to over £150,000 a year.

In 1906, 227 spinning mills spun 1,732,018 lb. of silk in France. A comparison of these figures with those of the present production of artificial silk which has also been given elsewhere at 5,000 tons per annum, is instructive.

There is no indication that the large production of artificial silk is materially affecting the gradual and increasing production of the real article; especially as the present production is practically confined to high

denier sizes (100 and above). These have a use which may be stated generally to be specific to the artificial product. Exactly what influence the finer counts will have on the production of the real product is a matter which must be left to the future.

It is obvious that an enormous industry must spring up before any appreciable result is noticed in the direction of a restricted output of real silk. One can only speculate on the effect of such a revolution, if the finer artificial silk is manufactured down to 15 denier, and ultimately equals in strength the natural product. A rough opinion may be formed as to the future of the industry on the statement made in a report by the United States Consul at Lyons that already 39,000 hands are employed in this industry. If this figure is correct—and it may not be very far from the mark—this industry will in the future give employment to a great number of hands, and become an increasingly important branch of the textile industry.

It is interesting in passing, to examine the position taken up by some authorities in this country, that there is an advantage in letting other nations work out new processes, and then establishing a position on the market with their early experience, and failures before us. The manufacture of this material under the conditions reviewed starts here with a financial handicap, for the leading Continental firms have already written down their works, plant, and rights, to a nominal amount, out of the abnormal profits in the past; they have a trained staff and great experience at their disposal. So that this must be set against any security arising out of such an assured position. On the other hand, it is claimed that in the two processes working to-day in this country, at Coventry and Yarmouth, respectively, the details of manufacture have been more successfully worked out here than on the Continent. The Viscose process is working on a large scale at Coventry, and there are indications that the Yarmouth research works may lead to an equally important development in the production and marketing of finer counts. The Flint Works is not yet producing yarn.

RELATIVE VALUE OF DIFFERENT MAKES TO ONE ANOTHER AND TO SILK.

However interesting many of the products may be, from the scientific standpoint, after all their commercial value and adaptability is of first importance. It is too early to attempt to define their relative values either from the point of view of cost, or their respective physical or chemical properties.

I would suggest, with all reserve, that up to the present time this so-called artificial silk has hardly come into direct competition with the natural product; and that this has been an important factor in favour of its development in the past. It has created and is creating uses for itself. Its selling price bears little relation in its fluctuations to that of real silk; but with the demand in excess of the supply this is not in itself conclusive evidence in this direction, but it tends to confirm other known facts.

With the material now being introduced in finer counts, it may certainly enter into direct competition with silk. The substitute must then chiefly claim advantage on the grounds of price value. With an improvement in strength in both the dry and wet state, competition must increase, as it has done in the past between the natural and artificial indigo, and alizarin products, and be governed by the relative conditions of supply. The last 15 years have seen a marked improvement in strength and so-called elasticity. There is no evidence that the limit has been reached, or even approached.

There is also the question of the relative "covering power" of the yarns when woven. The ordinary makes of artificial silk have only 60 per cent. of the covering power of natural silk. With an increase in the number of filaments in each thread a corresponding improvement in this respect naturally follows, as in the cellulose silk product. The limit to-day may be put at 60-75 per cent. of that of real silk. So that there is still room for improvement in this direction. The density of the cellulose substance

is about 10 per cent. in excess of silk, so that a covering power of 90 per cent. may be regarded as the maximum under equal conditions.

This is hardly the occasion to do more than point out the financial gain which has ultimately come to those who have carried this industry to its present state on the Continent. Notices which occur in the textile journals from time to time, indicate this in detail. The leading companies have paid steady and increasing dividends up to 50 per cent., or more (See Dreaper, *J. Soc. Dyers and Col.*, 1907, p. 5 and Dreaper and Davis, *ibid.* 1908, p. 294).

The manufacture of yarns by a process entailing the solution of the raw material as a preliminary step has, therefore, become a reality. It is evident that the future will see an extension of output, due to the growing appreciation of the value of these yarns, and the consequent extension of its uses.

DISCUSSION.

The CHAIRMAN said, as Mr. Dreaper had referred to certain matters being kept secret, he wished to emphasise that it was not intended to induce specialists to reveal their secrets in these general papers. These papers were rather to be of a general character. Although they would appeal in the first instance to specialists, and would also interest those grown up in other industries, these general papers were chiefly meant for the benefit of the younger members who wished to gain wide technological information. He would leave the discussion of specific points of this industry to those mainly interested in it, and therefore best qualified to speak; but he hoped there would be some general questions asked by those who were not actually engaged in the artificial silk industry. As Mr. Dreaper had mentioned the 1889 Exhibition and incidentally also quartz fibres, he vividly recalled the Chardonnet spinning-machine stowed away in a side alley of the Machinery Hall, and working without any attention; he was able to bring some of the fibres back with him to show to Professor Boys, who had at that time been producing quartz fibres, and was naturally interested in obtaining of the thinnest possible fibres for his modification of the Cavendish experiment. With regard to the question of the recovery of the solvents, which was only shortly referred to, could the author give any information as to the method of recovering the alcohol and ether by cooling to very low temperatures? Was it merely an idea that had been patented, or was it an actual process? He would like to mention Chardonnet's German patent 207,554; therein the absorption of vapours by means of sulphuric acid or by fats and oils was rejected, and substituted by absorption in aliphatic alcohols or their neutral esters.

Concerning the action of zinc chloride on cellulose, they knew that zinc chloride acted as a condensing agent on oils and fats, but very little was known of the rationale of the reaction. He should like to know how the process was controlled so as not to lead to the throwing down, as in the case of cellulose, of a horn-like or parchment-like product.

Mr. HENRY BRONNERT said the artificial silk industry had developed year by year in special ways which nobody had anticipated. At first, everybody thought that artificial silk would compete with natural silk, but it very soon proved to be an article quite by itself, and adapted also to entirely new articles which, in a great measure, it was the means of creating, *e.g.*, for ladies' wear, for trimmings, for ladies' hats, &c., all industries in which silk had not previously been used. There were now quite a number of new industries using this yarn, and the new factories which were being opened would be sure to find a good demand for their products. There were, without doubt, still further new fields in which artificial silk could be used to advantage.

Mr. E. F. CROSS considered that the paper was an opportune *exposé* of the present position and progress of this

remarkable industry. It was not the case that there was only so much business to go round, and a new factor appearing displaced so much of the old product. In the case of artificial silk, new classes of textiles had been introduced: the market showed that consumption was far from the limit, and he could increase Mr. Dreaper's total figures as stated, *viz.*, 3,000 tons, to 5,000 tons per annum; and further the demand was so far in excess of the supply that most factories were "sold forward" several months. Mr. Dreaper's insistence on his interesting new product of low deniers, down to a 15-denier thread, was justified as a technical forecast, but at present there was no demand outside the ordinary range of 100–130 deniers.

Mr. JULIUS HÜBNER asked Mr. Dreaper if he had any experience as to the specific gravity of the different kinds of artificial silk. He should think the difference in the dyeing properties of, say, different types of enpro-ammonia silk, would be most likely due to the after-treatment. It was well known that in the case of mercerised cotton, the affinity for the direct dyeing colouring matters changed very considerably if the cotton was dried before dyeing, as compared with cotton which had not been dried. The commonly accepted explanation for that was that the so-called water of hydration was removed by dyeing. If that was correct, the water of hydration could be got rid of very readily indeed, because he found that the dyeing property of cotton which had been treated with mercerising liquids, could also be altered by pressure. It was now possible to produce two—and more—colour effects on cotton fabrics if, after being treated with mercerising liquids and before drying, they were compressed in an ordinary embossing calendar. With regard to Mr. Cross's remark, that at present the market was not yet ripe for the finer deniers of artificial silk, he had a somewhat different experience, because the fine counts could be used for warps, &c., for which purposes the coarser deniers could not conveniently be employed.

Dr. J. C. CAIS said an important paper had recently been read before the French Academy on the recovery of waste alcohol and ether. The process there described was said to be remarkably economical, and consisted in compressing the air containing the volatile vapours under four atmospheres, passing it up a large tower, and cooling it gradually from the bottom, until at the top its temperature was about that of liquid air. By this means the water was eliminated at first, and there was none of the usual difficulty of freezing in the pump. He believed the yield was about 95 per cent. of the volatile vapours in the air. With regard to the suggestion of an alternative name instead of "artificial silk," in view of the fact that cellulose became "viscose," he ventured to suggest the name of "Celvis."

The CHAIRMAN said he thought that name would not do, because there was already a cloth called "Selvyt."

Mr. W. F. REID said there was one matter he should like a little more information about, as it interested him more particularly because the material produced was much nearer in chemical composition to silk than any of those spoken about that evening. He referred to Millar's gelatin silk. All those who had experimented with that knew that it was weak, but it had a most extraordinary lustre; and, although it could be made insoluble in water, yet it swelled in that liquid and became weaker still, so that it was quite unfit in that state for any fabric. He thought the future would bring some surprises in this connection; and, if they were once able to treat material like bone, cartilage, feathers, or wool in the same manner that they now treated cotton, they would get a product much nearer in its chemical composition and general properties to silk, and probably also in its elasticity and strength. He might also ask whether any filaments had been made in the way described for fishing purposes, which was the chief use for the silk of the silk-worm, next to that in textile industries. There was another matter

which had not been referred to, that of artificial bristles, and he should like to know if any information could be given about the actual use of these fibres for that purpose. Many years ago, when making experiments on these products, he found that the nozzles were very difficult to procure. The way he proceeded was, to make a carbon fibre, enclose it in a glass tube, and fuse the glass tube; the carbon fibre determined the diameter, and all the tubes were exactly the same. Then he burnt out the carbon, and had the nozzle. It was a very crude system, but efficient. He believed there were methods now of obtaining nozzles of exactly the diameter required; but he would like to hear any further information on that point, because it was very difficult indeed, considering that the orifices were invisible, to get them accurate.

Mr. O. GUTTMANN regretted that the author had not given more up-to-date information about the manufacture. It was incorrect to state that in 1855 Réaumur made artificial silk.

Mr. DREAPER said Réaumur was the first man to suggest the idea, and another man carried it out.

Mr. GUTTMANN said that as a fact Réaumur did suggest it in about 1730; but it was Adam Millar of Glasgow who, in 1855, produced artificial silk out of gelatin. He must also correct what he thought was an error in one of the tables. Mr. Dreaper had certainly succeeded in reducing the loss of strength due to moisture absorbed by artificial silk; but the loss in the case of cellulose silk was not 46 but 56 per cent. In speaking about the Chardonnet Factory at Besançon, he said that 2,600 hands produced one ton a day; that factory produced a good deal more than two tons a day. In fact, there were several Chardonnet factories which exceeded that figure. That was shown by the quantity of alcohol consumed, because the use of 4 kilos. of alcohol for 1 kilo. of artificial silk was, on the face of it, too much. He further stated that the Chardonnet silk contained from 9 to 14 per cent. of nitrogen. But nitro-cellulose, with 14 per cent. of nitrogen, had not so far been made; and Chardonnet's had only about 11 per cent. The recovery of the ether and the alcohol from artificial silk had been several times proposed and attempted, but unsuccessfully, until about six months ago. The recovery by means of low temperatures was, at present, at least, not practicable; it cost an enormous sum, as must be evident when it was borne in mind that in a spinning-room there were millions of cubic feet of air drawn out from which a very minute percentage of solvent had to be separated. What had been tried was to absorb the solvent, chiefly the ether, in sulphuric acid; and there were also other processes which had a large amount of success before them, namely, to absorb it in solutions of high boiling point, such as calcium chloride. The absorption with sulphuric acid had some prospect; but there was a difficulty in recovering the ether from the sulphuric acid again; there were by-products formed, which at present militated somewhat against the process—though no doubt these difficulties might be overcome. He would suggest "Lustrose" for the name of the product.

Dr. STEVENS said that whilst the majority of the fibres had smooth faces, he noticed that the fibre of the finer counts was irregular on the surface; it had some peculiar flattening and loops in places. Could the author account for that, and say whether it affected the quality and the properties of the silk?

Mr. F. J. FARRELL said he could confirm what had been said by Mr. Hübner, that there was a considerable demand for the finer counts for warp purposes; and, further, the supply of fine counts would create a demand. It was no use at present getting out patterns which it would be impossible to produce on a manufacturing scale. With regard to the recovery by condensation, he knew the recovery of benzene, at very low temperatures, from mixtures of air and benzene had not been successful. He also confirmed the statements that the production of artificial silk had created an entirely new class of fabrics; except in a few cases, it had not taken the place of natural silk at all. It seemed to him, although the all-artificial fabrics

shown were of considerable interest, that it was unlikely to become, for some time, of practical value by itself. It must depend for its use on the mixing with other fibres for the production of particular effects, but the amount which could be used in that way was very large. The producers need not be afraid, even if it were found impossible to produce fabrics entirely of artificial silk; it was very useful in conjunction with real silk, because of the possibility of obtaining two-colour effects, such as had been shown. With regard to the production of fine denier silk, it must be borne in mind that the finer the denier, the greater the covering power; and, as it was principally used for the purpose of effect, it was not the weight, but the covering power or the appearance, which had to be considered. He congratulated the author on the production of the 15-denier silk, which was a very notable achievement.

Dr. J. N. GOLDSMITH asked whether experiments had been made on the viscosities of the solutions which were to be squirted; and whether there was any relation between the viscosity and the breaking strength of the thread? Lehner's patent claimed that a solution of diminished viscosity was produced by the action of acetic and other acids; and he noticed that the Lehner thread had a breaking strain of 171.8, which was interesting in comparison with the Chardonnet of 74.2. They had been told that the Chardonnet process required very high pressures, and he concluded from that that the solution was of very high viscosity. *A priori*, one would suppose that a high viscosity would lead to a thread of high breaking strength. In a well-known book on textile fibres, reference was made to the difficulty of removing air bubbles from the thick solutions to be squirted. If there were air bubbles there were breaks in the thread. It was stated in this book that the air-bubbles were removed by applying high pressure to the solution, which was scarcely what one would expect.

Mr. W. P. DREAPER, in reply, said he could not, from personal knowledge, add to the remarks made concerning the process of cooling as a possible mode of recovering the alcohol and ether. It was a fact that within the last year a process had been patented by the Tubize Company in which sulphuric acid of a certain density was proposed; and this might be taken as an indication that certain improvements were being looked for, and that they might hope for a better process than the one in use to-day. It was not an easy thing to dissolve cellulose in zinc chloride, which would give a thread. There were certain secret manipulations which were necessary, and these had taken years to work out before a satisfactory conclusion had been arrived at. He agreed with Mr. Cross that artificial silk did not compete with the natural product. It might be a fact that the market was not ripe for the sizes under 100 deniers. The people who used these finer deniers were, generally speaking, not at all interested in the coarser counts; it appealed to a different class of manufacturer altogether; but there was certainly an increasing demand and inquiry for these fine counts. He had done no work himself on the specific gravity, but simply quoted the figures to which Mr. Guttmann had also probably referred, in which it was stated that this was about 10 per cent. denser than real silk, with the exception of the gelatin threads, which were said to be about the same as silk itself. With regard to this gelatin silk, to which Mr. Reid had called attention, he had certainly noticed its extreme brilliancy; but at the same time it would not be possible to weave or work up this product in competition with other makes.

As regarded the output, Mr. Cross mentioned that this was 5,000 tons per annum, and he believed that was correct. He had quoted figures recently published, when he said the output was 3,000,000 kilos.; but he thought it was an under-estimate. With regard to the irregular markings on the fine denier cellulose silk filament exhibited, they were not always present; they might be due to irregularities in the solution itself, or to the special conditions under which it was squirted, giving rise to surface tension effects or to some other causes of an indefinite

nature. Concerning viscosity and its influence, if any, he should say that it was only one of a very large number of factors controlling the manufacture. There were many ways of getting rid of air-bubbles, but he had never heard that external pressure was one of them; whether it would work or not, he should not like to say.

Nottingham Section.

Meeting held at Nottingham on Wednesday, November 17th, 1909.

MR. S. J. PENTECOST IN THE CHAIR.

THE AMOUNT OF SKIN SUBSTANCE DISSOLVED IN FELLMONGERS' COLLECTING LIMES.

BY J. T. WOOD AND S. R. TROTMAN.

In the *Leather Trades' Review*, of June 9, 1909, Mr. Seymour-Jones drew attention to various causes of looseness in sheep skins. By "looseness" is meant that condition of the skin fibres in which, instead of being compact and close like a piece of felt, they are loosely united like the texture of a blanket. In a short introduction the editor remarks:—"It is not too much to say, perhaps, that the matter of sheep pelt improvement is almost of national importance, for the demand existing to-day for high grade sheep pelts can hardly be met, whilst, on the other hand, common stock can hardly find a purchaser at remunerative prices."

Amongst the causes of looseness, a prominent place is given to the loss of skin substance caused by the condition of the lime liquor in which the pelts are collected in fellmongers' yards before being sent in to the leather dresser or tanner. The common practice is to throw the fellmongered pelts into an old lime, which is claimed to be a weak one. Some yards clean the lime-pits out after each lot of pelts and others after a few lots have been through, others every six or twelve months, and in one case they never remember cleaning out the limes, but they were freshened up from time to time. Here we have cases—and they are but too numerous—where fellmongers, not through carelessness, but through want of knowledge, keep the old limes for storing up the pelts pending sale.

Lime alone is capable of dissolving the interfibrillar substance of the skin, but in its fresh condition it will not attack the actual skin fibres. Out of each lot of pelts the lime dissolves a certain quantity of the interfibrillar substance, and this affords nutriment for bacteria, with which the pulled pelts are swarming. This bacterial lime is now capable of attacking the fibres of the skin, and thus taking out valuable substance, which should be made into leather. A new lime is antiseptic, and if pelts, after pulling, are washed in clean water and put into such a lime, they are practically sterilised for the time being, and will keep intact until the lime has dissolved out sufficient skin substance to act as nutriment for bacteria. It is these bacteria which produce the ammonia compounds, and which effect the solution of the skin substance.

The presence of dissolved skin substance in the limes may be demonstrated by placing 50 c.c. of the filtered lime liquor in a 100 c.c. cylinder, adding 10 c.c. of glacial acetic acid, and filling up to 100 c.c. with a saturated solution of common salt; the dissolved skin will be precipitated and float to the top. This method has been proposed by Gordon Parker and others, and has been in practical use in the tan-yard for many years.

In the Trent Bridge Laboratory, we have used hydrochloric acid in excess, and saturated the solution with salt. In this way somewhat more skin substance is

precipitated than by the method mentioned by Seymour-Jones (*"Leather Trades' Review,"* June 9, 1909) in which the solution is made only slightly acid, and not completely saturated with salt. In the article referred to the number of c.c. occupied by the skin in the tube after standing for one hour are termed "degrees," and for works use this is a convenient way of expressing it.

At Trent Bridge Works, Nottingham, we have made a number of analyses of fellmongers' collecting limes, and by permission of Sir John Turney, we are able to give the results of these analyses. The limes were obtained from districts as far separated as Scotland and Cornwall, and thus represent a fair sample of the condition of fellmongers' limes in this country.

The following are the details of the analytical methods employed. The liquors were filtered through a thick plug of cotton wool for analysis. The total alkalinity was determined by titrating 10 c.c. of the filtered lime liquor with N/10 hydrochloric acid, using phenolphthalein as indicator. A portion of the filtered liquor was boiled in a Kjeldahl apparatus, the expelled ammonia being collected in excess of decinormal acid and titrated (see foot note). The residue in the flask was titrated with phenolphthalein and decinormal acid, the acid used being calculated to lime. Soda, if present, was of course included in this figure, but there was in no case reason to suspect its presence.

The dissolved hide substance was obtained from the total nitrogen by multiplying by the factor 5.62. In determining the total nitrogen, the liquor was first acidified and concentrated, the ammonia already present being assumed to be derived from hide substance. This is undoubtedly the case, since the degradation of the skin under the influence of putrefactive bacteria rapidly passes the peptone stage with the production of amines and ammonia. A dilute solution of gelatin free from ammonia when incubated with a drop of lime liquor gave reactions for ammonia in three days.

The following is a further analysis of lime liquor 17* in which the nitrogen has been differentiated:—

Percentage of nitrogen present as hide substance.....	35.5
Percentage of nitrogen present as ammonia and bodies capable of yielding ammonia when boiled with alkali.....	21.4
Percentage of nitrogen present as peptone	43.1

The nitrogen as albumose or hide substance after the first stage of hydrolysis was determined by precipitation with zinc sulphate. Ammonia and ammonia-yielding compounds were obtained by direct distillation, and the difference between the sum of these and the total nitrogen was assumed to be peptone nitrogen.

The results on the table are of interest, as we believe they show for the first time in what a bad condition many of these limes are. In general, the older the lime the more skin substance it contains in solution, but the factors of temperature and quantity of skins put through cause this to vary. If it can impress upon fellmongers, and those who have to deal with pelts, what waste is going on in this direction, it may be pointed out that an amount of skin substance equal to a good pelt, weighing 7 lb., is dissolved in every 20 litres (about two buckets) of sample No. 4. For the mean of all the limes examined, such a pelt is contained in every 63 litres of liquor. The minimum shows one pelt in 300 litres (sample 8), but this is practically dirty water through which the skins have been drawn.

As to the nature of the skin substance dissolved in the limes, Van Lier (see this J., 1909, 1150) has shown that the true interfibrillar substance of skin is totally extracted by means of weak lime solution (about 0.7 gm. of lime per litre) in from 8 to 28 days, according to the nature of the skin (eight days for cow and horse; 28 days for calf), but this is for quite fresh lime solution renewed every 24 hours. The alkalinity of such a solution is 2.25 c.c. N/1 per 100 c.c. In the limes shown in the table it will be seen that the alkalinity in one case reached 12.8 c.c.

* The more accurate method of estimating ammonia in lime liquors of Procter & McCandlish (this J., 1906, p. 254), was not used, as we considered the distillation method sufficiently accurate for works control.

In addition to this excessive alkalinity, a microscopical examination shows the presence of numerous bacteria in these limes, which undoubtedly attack the actual fibre of the skin, and take out substance which should be made into leather.

In a paper entitled "Recent progress of tanning as a chemical industry" (this J., Nov. 30, 1903, p. 1274) one of us has already suggested that the role of bacteria in the liming process ought to be studied in our research laboratories in the same way that the bacteria in tan liquors, bates, and drenches have been investigated by Andreasch, Becker, and Wood. The various species growing in the liquors should be isolated and their life history and action on skin worked out. In such a way the process of liming as carried out in practice would be thoroughly illuminated.

Approximately 0.2 per cent. of nitrogen corresponding to 1.12 per cent. of skin substance is equivalent to 7.6 of Seymour-Jones' degrees, so that when the skin substance passes this amount it is no longer possible to distinguish between the limes, as the whole tube is filled with a mass of separated skin.

In conclusion, we recommend the following limits for a lime in which pelts are collected:—Lime in solution not to be less than 0.1 gm. of CaO per 100 c.c. The alkalinity should not exceed 6 c.c. N/1 per 100 c.c. To attain this standard the pelts would require to be well washed in clean water after pulling, and the lime pit cleaned out and renewed after two lots of pelts have been put through.

We would suggest that the Fellmongers' Association might advise fellmongers gratis as to these conditions, the ascertainment of which is of a very simple character.

Analysis of fellmongers' limes, used for collecting sheep pelts (grms. per 100 c.c.)

No. of analysis.	Lime (CaO) in solution.	Alkalinity as c.c. normal acid per 100 c.c.	Ammonia.	Total nitrogen by Kjeldahl's method.	Dissolved hide substance.

Obituary.

LUDWIG MOND.

Dr. Ludwig Mond, F.R.S., born on March 7th, 1839, at Cassel, Germany, was a son of the late Moritz B. Mond, a merchant in that town. He attended the Polytechnic School there, and subsequently studied at the Universities of Marburg and Heidelberg, where he was the pupil of Bunsen. After leaving Heidelberg he held several appointments in chemical works in Germany. He came to England in 1862 with the object of introducing a process for the recovery of

sulphur from alkali waste, and became associated with Mr. John Hutchinson, of Widnes, at whose works he perfected his system. Two years later he undertook the erection and management of a Leblanc alkali works at Utrecht, Holland. In 1867 he settled definitely in England, and installed his sulphur recovery process in a number of British and foreign alkali works. He met early in 1872 Ernest Solvay, of Brussels, who had carried out successfully near Charleroi his new process for the manufacture of soda by the saturation of brine with carbon dioxide and ammonia. Solvay gave Mond the fullest opportunity to examine his process, and the latter was so struck with its possibilities that he entered into an agreement with Solvay for its introduction into the United Kingdom. In conjunction with Mr. (now Sir) John T. Brunner he established in 1873 the firm of Brunner, Mond & Co., and erected works near Northwich for carrying out the Solvay process, works which have grown until they have become the largest alkali manufactory in the world.

Another question to which he applied himself was that of the economical utilization of fuel; and the outcome of his work on this subject, which began about 1879, was the invention of the system of producing power-gas known by his name. At every stage of the process the most ingenious arrangements were introduced to utilize the thermal energy and prevent waste, and the volume of power-gas produced from each ton of fuel is stated to be about 150,000 cubic feet, sufficient to develop about 2,000 indicated horse-power hours when consumed in gas engines.

Many experiments were also made by him in the hope of utilizing Grove's gas battery for the production of electricity on an industrial scale; and though they did not enable him to achieve success in this particular object, they incidentally led him to the discovery of a valuable process for the extraction of nickel from its ores. Being anxious to use the hydrogen contained in producer-gas for the purposes of the battery, he sought for some means of removing the accompanying carbon monoxide; and in the course of the work, in which Carl Langer and Friedrich Quincke took part, it was noticed that the latter gas combined with nickel to form a substance now known as nickel carbonyl, which is remarkable as being a volatile compound formed at a temperature below a red heat, and which affords a means by which nickel can be separated from other metals. This compound, which was first described in 1890, was the first representative of an entirely new group of compounds, other members of which Mond subsequently discovered in the shape of iron, cobalt and other carbonyls. On the basis of these observations a large experimental plant for the reduction of nickel from its ores was erected at Smethwick in 1892, and in time the process was developed into the successful form in which it is now worked by the Mond Nickel Company at Swansea.

His connection with the Society of Chemical Industry lasted from its first inception to the end of his life. In January, 1880, he took the chair at a meeting held in Liverpool to establish a "Lancashire Chemical Society," and in the following April, at Manchester, it was he who advocated the extension of this local society into a national one devoted strictly to the interests of applied chemistry. When this society was founded in 1881 he was appointed Hon. Foreign Secretary, a post which he continued to hold, with one short interval, for the rest of his life. That short interval was spent as President and Vice-President of the Society. In August, 1881, he undertook the arrangements for the foundation of the JOURNAL, and to him it owes its general plan and order, which are substantially the same to-day. The contract for printing was drawn up by him in conjunction with the late Mr. George E. Davis and Mr. Watson Smith, and he guaranteed the cost until the JOURNAL should prove self-supporting.

In 1888 he was elected President. His address in 1889 was devoted primarily to the consideration of the

various methods of ammonia production, and incidentally to cyanides and power gas. In 1906 he was awarded the Society's medal for his conspicuous services to Applied Chemistry by his researches, discoveries, and improvements in processes. He was chairman of the Chemical Section of the British Association at the Liverpool meeting in 1886. He was the chief promoter and supporter of the International Congress of Applied Chemistry held in London last May. His generous hospitality will long dwell in the memories of those who were present.

He was a munificent benefactor of scientific research. It was through him that the Royal Society was enabled to bring out its international catalogue of scientific papers, and he made generous contributions in aid of the investigations carried out at the Royal Institution. Further, he transferred to the managers of the latter body, under a trust endowment, the freehold of the house adjoining its premises in Albemarle Street, for the purposes of a laboratory for research in pure and applied science, to be known as the Davy-Faraday Laboratory of the Royal Institution. This laboratory, which was formally opened by King Edward (then Prince of Wales) in 1896, he not only furnished with the most modern apparatus, but he also placed in the hands of the managers of the Royal Institution an ample annual endowment sufficient to maintain it in a state of thorough efficiency.

For some years past he had been in delicate health, and was accustomed to winter in Rome. He would have been President of the Chemical Society this year but had to decline office from this cause.

In November he became seriously ill, and died at his house in Avenue Road, Regent's Park, on December 11th, in his seventy-first year. He was buried in a mausoleum designed by himself in St. Pancras Cemetery, East Finchley, on December 14th, and his remains were followed to the grave by six past Presidents of the Society of Chemical Industry, and other members, with many other representatives of science.

List of Papers contributed to the Journal of the Society.

- "Ammonia Soda Process, Origin of the," 1885, 527.
- "Carbonyls, Metallic," 1892, 750. Abstract.
- "Chlorine, History of Manufacture of," 1896, 783.
- "Development of Voltaic Electricity by Atmospheric Oxidation of Combustible Gases," 1890, 42.
- "Nickel Carbon Oxide and its Application in Arts and Manufactures," 1891, 836. Abstract.
- "Nickel Extraction Process, History of," 1895, 915.
- "Patent Laws as applied to Chemical Inventions" (First Proceedings, 1881, 53).
- "Patent Laws Committee, Report of," 1882, 252.
- "Presidential Address," 1889, 505.

Journal and Patent Literature.

PATENT SPECIFICATIONS may be obtained by post by remitting as follows:—

English.—8d. each, to the Comptroller of the Patent Office, W. Temple Franks, Esq., Southampton Buildings, Chancery Lane, London, W.C.

United States.—1s. each, to the Secretary of the Society.

French.—1 fr. 25 c. each, to Belin et Cie., 56, Rue des Francs Bourgeois, Paris (3e.).

German.—1 mark each (with full particulars) to Kaiserlich Patentamt, Berlin, Germany.

I.—PLANT, APPARATUS, AND MACHINERY.

PATENTS.

Drying dissolved leather, concentrated or coagulated blood, paints or pigments and other semi-solid substances: Apparatus for — K. Hofmann and J. J. Main, Leicester. Eng. Pat. 25,216, Nov. 23, 1908.

IN drying apparatus in which the material to be dried is fed upon the upper surface of a pair of cylinders heated internally, and rotated in contact in opposite directions, trouble often arises owing to the material accumulating at the ends of the spaces between the upper surfaces of the cylinders, passing on to the bearings and frame, and clogging the action. This defect is sought to be overcome by increasing the length of the axes of the cylinders so as to provide a space at each end between the cylinders and the frame. Further, plates, movable in the direction of the axes of the cylinders and supported from above, are pressed by springs against the ends of the cylinders so as to form ends to the space between the upper surfaces of the cylinders. One of the rotating cylinders is supported on ball bearings in movable journal-boxes, kept in position by springs, which allow the cylinders to separate slightly should an unusually large piece of material be fed on to the surface.—W. H. C.

Extraction of grease or oil from condensed water: Process for the — E. Hatschek, London. Eng. Pat. 26,228, Dec. 1, 1908.

THE claim is for the use, as filtering material, of a layer of precipitated calcium carbonate resulting from the manufacture of caustic soda from sodium carbonate. The layer of calcium carbonate is spread over the surface of the filtering apparatus and allows the water to pass

through, but prevents the passage of the grease, which accumulates on the surface and is removed from time to time.—W. H. C.

Separating solids of different densities: Machines for — R. S. Baxter, Broughty Ferry, N.B. Eng. Pat. 2544, Feb. 3, 1909.

THE mixture of solid bodies of different densities is placed in a V-shaped trough, one of the sides of which is formed of vibratory bars. An oscillatory motion is imparted to the bars by any suitable means, and the shaking which ensues causes the materials to arrange themselves in two layers. The lighter particles are discharged over the edge of the trough and the heavier ones through doors near the bottom, which are controlled by springs.—W. H. C.

Water distribution devices specially adapted for use in cooling towers. D. E. Morison, Hartlepool. Eng. Pat. 18,402, Sept. 2, 1908.

THE water is fed into a tank placed on the top of the tower and flows into the latter through a number of vertical nozzles which pass through the bottom of the tank. The nozzles consist either of vertical earthenware pipes with a conical bore or of cast iron cylindrical pipes with an earthenware nozzle or jet at the lower end. The upper ends of the pipes, which project slightly above the bottom of the feed-tank, are enlarged, or are cut away at one side, in order to obtain a "solid" jet of water from the nozzle. The jets of water impinge upon spraying saucers or trays placed within the tower directly below each of the nozzles. The trays have upturned, serrated edges which may be varied as to inclination and height in order to vary the angle at which the spray is projected from their upper surfaces.—W. H. C.

Filtering apparatus. F. Sheard, Dewsbury, Eng. Pat. 20,140, Sept. 2, 1909.

THE liquid to be filtered enters through the pipe, G, and passes through the sand, E, which rests on the perforated plate, D. The perforations in this plate have domed covers, *d*, pierced with small holes. Below D, is a layer of pebbles, C, supported on the perforated plate, B. After passing through the sand and pebbles, the liquid is discharged through the pipe, J. When it is necessary to cleanse the sand, the supply of water is shut off by the tap, *g*, and clean water is forced through the pipe, L, into the annular pipes, *k*, and the radial pipes, *k*¹; the latter have perforations, M, closed by non-return valves which open only by pressure from within. At the same time the wedge-shaped agitator blades, *f*, provided with pointed, wedge-shaped projections, *f*¹, are rotated by the shaft, F, so as to stir up the sand with the washing water. The latter flows away through the pipe, N, carrying the impurities with it.—W. H. C.

Filter for viscous liquids. L. Morane. Fr. Pat. 403,107, May 17, 1909.

A SERIES of circular filter-frames provided with central holes is arranged in a vertical cylinder and held in position by a hydraulic cylinder below. The liquid to be filtered enters the vertical cylinder, and after filtration, leaves the apparatus by means of the tube formed by the central holes of the frames, which communicates with an exit pipe on the cover of the cylinder. Each frame consists of two discs, one of which is provided with radial ribs forming channels to carry the filtrate to the central tube, while both are pierced with holes. The surfaces carrying the filtering material, which is secured by wires, are slightly conical. A balanced cover on the top of the cylinder, enables the frames and press-cakes to be easily removed.—J. W. H.

Filter-press for laboratory use. C. C. Leclaire. Fr. Pat. 403,115, May 18, 1909.

THE claim is for a compact filter-press for laboratory use, in which the liquid to be filtered does not come into contact with the pump. A circular disc filter-frame is mounted at the top of a receiver containing the liquid to be filtered. An agitator in the conical base of this receiver, and connected with the lever of the hand pump, prevents settling of the precipitate. Compressed air from the pump enters the receiver and forces the liquid through a vertical tube into the filter-frame. Provision is made for washing the press-cake and for working with vacuum. Screw-down valves are used in place of cocks.—J. W. H.

Evaporating apparatus. J. Parker, Assignor to Kestner Evaporator Co., Philadelphia, Pa. U.S. Pat. 940,473. Nov. 16, 1909.

THE evaporator consists of a steam chamber, containing a number of vertical tubes. Liquid is fed into the base of the tubes. A chamber enclosing the upper end of the steam chamber, and in open communication with the upper ends of the tubes, receives the vapour, and also the entrained liquid. Centrifugal devices are provided for separating the entrained liquid from the vapour, the former being then led to a point of discharge below the level of the top of the tubes, whilst the latter is removed at a point below the liquid-outlet.—G. W. McD.

Dissolving salts; Apparatus for —. E. Nitschke. Ger. Pat. 215,823, March 4, 1908.

THE apparatus is of the type in which the outlet in the bottom of the dissolving vessel for the discharge of the undissolved residue, serves also as a filter for the saturated solution. The outlet is provided with a conical or cylindrical perforated pipe, which projects upwards to such a distance that its upper part is above the level of the undissolved substance. Below this level, the pipe is provided with a valve, which is closed whilst the dissolving operation is proceeding, the solution being discharged through the portion of the perforated pipe below the valve. When the operation of dissolving is completed, the valve is opened, so that the solution can be withdrawn rapidly. The valve is then again closed, and suction applied to the outlet pipe, in order to drain the undissolved substance.—A. S.

Kilns; Annular —. H. Köddewig, Bochum, Germany. Eng. Pat. 24,528, Nov. 14, 1908.

SEE Fr. Pat. 396,233 of 1908; this J., 1909, 476.—T. F. B.

Mixtures; Process for obtaining intimate —. E. Dor-Delattre, Liege, Belgium. U.S. Pat. 939,989, Nov. 16, 1909.

SEE Eng. Pat. 24,958 of 1907; this J., 1908, 492.—T. F. B.

ERRATUM. This Journal, Dec. 15, 1909, page 1239, col. 2, line 19 from bottom, for "Diamond" read "Diamand."

II.—FUEL, GAS, AND LIGHT.

Illumination; Needs of —. S. P. Thompson. Inaugural Address to the Illuminating Engineering Soc., Nov. 18, 1909. J. Gas Lighting, 1909, 108, 535–536.

THE author pointed out the importance of getting international agreement as to the unit of light, and as to what shall be taken as the requirement for the illumination of a surface. There is, at present, no agreement in the standard of illumination. In England, it is the custom to

deal with illumination in terms of the candle-foot—meaning the intensity of illumination on a surface situated at a distance of 1 foot from a light of 1 candle. Reading is impossible with illumination so small as $\frac{1}{10}$ candle-foot, and is fatiguing at $\frac{1}{2}$ candle-foot. It is, however, comfortable with $1\frac{1}{2}$ or 2, 3, or 4 candle-foot. If the illumination exceed 8 candle-foot, the glare is too great. Very seldom in any ordinary room does the artificial illumination exceed 3 candle-foot. By day, on a writing-table placed near a north window, or, in fact, near any window receiving direct illumination, there will be from 3 to 4 candle-foot. "Well lit" was at one time vague; now there are exact terms for expressing it. For a writing-table one must have at least $1\frac{1}{2}$ candle-foot. In school-rooms on the desks, the illumination should not be less than 1 candle-foot.

There are three distinct things a photometer may be employed to measure. First, the intrinsic brightness or the effulgence of a source of light, the amount of which is expressed by saying it has a power equal to so many candles. Secondly, photometry is wanted for illumination at the surface, to be expressed in terms of candle-foot, candle-metre, or lux. Illumination is independent of the nature or colour of the substance on which the illumination falls. Photometers are needed to measure not how much light looks on a surface, but how much light falls upon it. Thirdly, photometry is wanted to measure the luminosity or the specific brightness of a surface. The amount of light given off from an illuminated surface, per square inch, varies enormously. It will depend upon the quantity of light thrown by the source, and upon the surface itself. The photometry of the specific brightness of an illuminated surface has been very little studied. It is, however, of great importance; and accurate figures are needed. It should be possible to say just how much a certain wallpaper or a certain coloured paint will throw back the light that it receives.

With a standard of illumination, and simple portable photometers with which to measure the illumination, there can be no excuse for ignorance in respect of the lighting of any place. The Home Office, the author considers, ought to thoroughly look into the subject of illumination, and place the illumination of factories and workshops on a proper scientific basis. At present, all they ordain is that such a building must be "adequately lighted." There are various views as to what constitutes adequate illumination; and the employer should be given proper regulations, and made to give proper illumination. In Holland, an adequate lighting standard for ordinary factories is prescribed at from 10 to 15 candle-metres, or rather more than 1 candle-foot.

PATENTS.

Liquid fuel; Utilization of the vapours or gases derived from — in the heating of steam boilers and the like. J. Wilson and R. Prescott, Ulverston, Lancs. Eng. Pat. 26,248, Dec. 4, 1908.

THE patent relates more especially to the use of liquid fuels for heating the steam generators of steam-driven motor-cars. To permit of the use of benzene, coal-tar naphtha, paraffin oil, and other fuels liable to form deposits owing to incomplete combustion, the following process is adopted. The fuel is first passed through a coil in which it is vaporised at a comparatively low temperature, superheated steam from a second coil is mixed with the vapour, and the mixture is passed through a strongly heated coil in which gasification takes place. The mixture is next forced through a nozzle so as to draw in air, and the combustible mixture is finally led to the burner orifice.—A. T. L.

Illuminating gas; Process and apparatus for the continuous manufacture of —. Martin und Pagenstecher Ges. m.b.H. and K. Meitzler. Ger. Pat. 214,661, Jan. 6, 1906.

THE gas is manufactured in a vertical retort, consisting of an upper portion constructed of refractory material, resting on a lower portion which is constructed of metal, and surrounded by conduits through which the secondary

air supply is passed; the air serves to cool the coke and is itself preheated. Dampers are provided in the heating flues, so that the supply of heat to the middle and upper portions of the retort can be controlled. The middle portion of the retort is heated most strongly. A movable pipe passes down through the top of the retort and extends to the zone between the middle and upper portions of the retort; the distillation gases are withdrawn through this pipe, so that the gases evolved in the earlier and later stages of distillation respectively are withdrawn together, but do not mix inside the retort. At the lower end of the retort there is a coke-breaking device, and a jet through which a steam blast is injected during the discharge of the coke. The steam is directed against the discharge outlet, so as to prevent entry of air.—A. S.

Gas purification; Apparatus for —. S. Chandler, London. Eng. Pat. 27,841, Dec. 22, 1908.

THE patent relates to wet washer-scrubbers of the type in which a series of rotating wheels or other scrubbing devices is mounted on a horizontal shaft, each scrubbing device working in a separate compartment of the apparatus, and the gas passing successively through each compartment, and flowing radially from the centre to the circumference, and *vice versa*, in alternate compartments. In order to utilise the whole surface of the scrubbing devices, these do not dip into the washing liquor, but a sump is arranged below each compartment, and pumps are provided for circulating the liquor and spraying it on to the scrubbing devices at their highest point. The sumps are connected with one another in cascade fashion, and water is introduced into one of the end sumps, strong liquor being drawn off at the other end. The sumps may be in the form of separate tanks connected to the scrubber by piping, when it is desired to convert existing scrubbers. The bosses of the scrubbing devices may be hollow as described in Eng. Pat. 28,387 of 1907 (this J., 1909, 83).—A. T. L.

Ammonium sulphate; Process of extracting — from distillation gases. Gewerkschaft der Steinkohlenschee "Mont Cenis." Fr. Pat. 403,050, May 14, 1909. Under Int. Conv., May 15, 1908.

IT is proposed to use acid directly as the absorbing liquid for the extraction of ammonia from distillation gases (e.g., in coke and gas works). The gases are cooled to a temperature of 15°–20° C., which causes the condensation of tar, water vapour, and about one-fifth of the ammonia, and are then made to pass into a solution of ammonium sulphate, preferably of 29°–35° B., containing about 5 per cent. of free sulphuric acid, the ammonia extracted from the condensed ammoniacal liquor being passed into the same solution. The heat produced by neutralisation prevents possible dilution of the absorbent by the condensation of water vapour from the gas, and ammonium sulphate, free from tar, separates continuously.—F. SOBN.

Illuminating gas; Liquefaction of — under pressure. H. Blau, Augsburg, Germany. Eng. Pat. 2292, Jan. 30, 1909. Under Int. Conv., Jan. 31, 1908.

SEE Fr. Pat. 398,839 of 1909; this J., 1909, 1026.—T. F. B.

Coal-gas and carburated water-gas; Process of manufacturing —. W. Thomas, Vancouver, B.C. U.S. Pat. 940,289, Nov. 16, 1909.

SEE Eng. Pat. 16,498 of 1906; this J., 1907, 861.—T. F. B.

Distillation of bituminous coal or similar carbonaceous substances. T. Parker, Ironbridge. U.S. Pat. 941,352, Nov. 23, 1909.

SEE Eng. Pat. 14,169 of 1908; this J., 1909, 879.—T. F. B.

Gas washer. W. Feld, Hünningen on Rhine, Germany. U.S. Pat. 940,103, Nov. 16, 1909.

SEE Eng. Pat. 15,683 of 1908; this J., 1909, 1239.—T. F. B.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

*Mineral oils in Greece; Customs duties on ——. See XII.
PATENTS.*

*Dehydrating liquids [tar, etc.]; Apparatus for ——. Soc.
du Gaz de Paris. Fr. Pat. 402,917, May 11, 1909.*

THE apparatus consists of an oil-bath containing a serpentine coil leading into an expansion chamber containing baffle-plates. The oil, tar, or other liquid to be treated is fed into the serpentine coil, where it becomes heated to a temperature above the boiling point of water before being discharged on to the baffle-plates in the expansion chamber. The steam generated is carried away to a condenser by means of one pipe, while the dehydrated liquid flows away by another.—J. W. H.

Bitumen from lignites; Process for the purification of ——. Montanwachs-Fabrik Ges.m.b.H. Ger. Pat. 216,281, June 4, 1907.

THE crude bitumen from lignites cannot be purified by treatment with sulphuric acid in the ordinary manner, owing to the great amount of decomposition, and the difficulty of recovering the solvent used for dissolving the bitumen. It has now been found that if the "resin" be removed from the crude bitumen, of which it forms from 15 to 25 per cent., the difficulties mentioned are avoided. The process claimed consists in dissolving the crude bitumen in hot petroleum spirit (benzene), and allowing the solution to cool, whereupon the "resin" remains dissolved, whilst the "wax" separates and can be subsequently purified by treatment with sulphuric acid, &c., in the usual manner. The "resin" may be recovered from the benzene solution: it has a reddish-brown colour and softens at 50°–60° C.—A. S.

Tar, tar-oils, pine-oils, and allied distillation products; Process for the purification of ——. O. Sprenger, Bremen, Germany. Eng. Pat. 3074, Feb. 8, 1909.

SEE Fr. Pat. 399,760 of 1909; this J., 1909, 932.—T. F. B.

Artificial resins from pyroligneous products. Fr. Pat. 402,907. See XIII.B.

IV.—COLOURING MATTERS AND DYESTUFFS.

Fluorescent substance derived from physostigmine. Gaubert. See XX.

PATENTS.

Azo dyestuffs; Production of ——. P. A. Newton, London. From Farbenfabr. vorm. F. Bayer und Co., Elberfeld, Germany. Eng. Pat. 1397, Jan 20, 1909.

THE dyestuffs are produced by combining in acid solution the diazo compounds of alkyl or aryl ethers of 5-nitro-2-aminophenol or their derivatives or substitution products with derivatives of 2-amino-8-naphthol-6-sulphonic acids alkylated or arylated in the amino group. For example 168 parts of 5-nitro-2-aminoanisole are dissolved in 1000 parts of 20 per cent. hydrochloric acid and 700 parts of water. The solution is boiled and diazotised by adding 69 parts of sodium nitrite. The diazo-solution is filtered and treated with sodium acetate and then, while still cooled, is stirred with an aqueous solution of 315 parts of 2-phenylamino-8-naphthol-6-sulphonic acid and 136 parts of crystallised sodium acetate. The dyestuff produced in this way gives on wool from an acid bath, black shades fast to light and milling.—S. H. H.

Anthracene derivatives; Production of new ——. Farbenfabr. vorm. F. Bayer und Co. Fr. Pat. 403,205, May 21, 1909. Under Int. Conv., June 25, 1908, and March 4, 1909.

1-AMINOANTHRAQUINONES or their derivatives are con-

densed with epichlorhydrin and the product is sulphonated. Example: A mixture of 150 parts of 1:4-diaminoanthraquinone, 1500 parts of glacial acetic acid and 375 parts of epichlorhydrin is heated at 30°–35° C. for several days until the mixture becomes blue. The product is filtered, dried, and 30 parts are warmed with 500 parts of concentrated sulphuric acid at 30° C. until a sample is soluble in water. The mixture is thrown on ice, and the dyestuff salted out and separated by filtration. It gives pure blue shades on wool.—J. C. C.

Disazo dyestuffs; Production of ——. Farbenfabr. vorm. F. Bayer und Co. Fr. Pat. 403,208, May 21, 1909. Under Int. Conv., June 30, 1908.

DISAZO dyestuffs are obtained by combining the tetrazo compounds of *m*- or *p*-diaminodiphenylurea or their homologues with one molecule of a *m*-phenylenediamine-sulphonic acid or *m*-aminophenolsulphonic acid, or their homologues or analogues, and one molecule of *m*-phenylenediamine, *m*-tolylendiamine, *m*-aminophenol, resorcinol or their derivatives which do not contain a sulphonic acid group. An example is given in which *m*-diaminodiphenylurea is tetrazotised and combined with one molecule of *m*-phenylenediaminesulphonic acid and one molecule of *m*-phenylenediamine. The dyestuff gives orange yellow shades on cotton which, on development with diazotised *p*-nitraniline, become rich yellowish brown.—J. C. C.

Anthracene vat dyestuffs; Production of ——. Farbenfabr. vorm. F. Bayer und Co. Fr. Pat. 403,259, May 22, 1909. Under Int. Conv., Nov. 7, 1908.

VAT dyestuffs are obtained by condensing *p*-aminoalkoxyanthraquinones with halogenated anthraquinones, or *p*-halogenated alkoxyanthraquinones with aminoanthraquinones. They furnish vats which yield fast Bordeaux to violet shades. Example: A mixture of 30 kilos. of 1:4-aminomethoxyanthraquinone, 30 kilos. of 2-chloroanthraquinone, 4 kilos. of cuprous chloride, 25 kilos. of anhydrous sodium acetate, and 300 kilos. of naphthalene is boiled for 6 hours. The dyestuff is precipitated by benzene, and washed with benzene, glacial acetic acid, and water. It produces a Bordeaux shade on cotton.—J. C. C.

Diphenyl-naphthylmethane dyestuffs; Process for preparing acid chrome ——. Farbenfabr. vorm. F. Bayer und Co. Ger. Pat. 216,305, Oct. 22, 1908.

THE disulphonic acids of 2-hydroxy-1-naphthaldehyde (e.g., the 3:6- or 3:7 disulphonic acids) are condensed with two mols. of salicylic or *o*-cresotinic acid to form leuco-compounds which, when oxidised, are converted into diphenyl-naphthylmethane dyestuffs. They dye wool from acid baths, and the shades produced are rendered deeper and faster by subsequent chroming.—T. F. B.

Vat [indigo] dyestuff; Brown — and process of making same. G. Engi and H. Kappeler, Assignors to Soc. Chem. Ind. in Basle, Basle, Switzerland. U.S. Pat. 940,586, Nov. 16, 1909.

4:4'-DIAMINOINDIGO is treated with halogenating agents. The resulting substances dye cotton brown shades from alkaline vats. The dyestuff obtained by brominating the diaminoindigo, which is specifically claimed, dyes cotton reddish-brown shades.—T. F. B.

Anthracene; Production of a series of new derivatives and dyestuffs from ——. Badische Anilin und Soda Fabrik. Twelfth Addition, dated April 30, 1909, to Fr. Pat. 349,531 of Dec. 21, 1904.

THE dyestuffs described in the ninth addition to the chief patent (this J., 1907, 251) when halogenated, yield new dyestuffs. The dyestuff prepared by chlorinating isoviolanthrene (obtained from monohalogenated benzanthrone) either by means of sulphuryl chloride or chlorine, is the dichloro-derivative and gives a blue vat, dyeing vegetable fibres in blue shades, which when

was-hed and dried, become bright reddish violet. Bromination of isoviolanthrene leads to the dibromo-derivative which also gives a blue vat dyeing vegetable fibres in blue shades which become bluish violet on washing and drying.—J. C. C.

Vat dyestuffs of the anthraquinone series; Process for preparing —. Badische Anilin und Soda Fabrik. Ger. Pat. 215,182, Dec. 10, 1908.

NEW vat dyestuffs of the anthraquinone series are produced by the action of one mol. of a diamine of the benzene or naphthalene series on two mols. of a halogenide of anthraquinone-2-carboxylic acid or one of its derivatives. The dyestuffs dye bright yellow to brownish-orange shades from the vat, which are fast to washing, chlorine, sulphur, potting, and light.—T. F. B.

Anthraquinone; Process for preparing —. Chem. Fabr. Grünau, Landshoff und Meyer A.-G. Ger. Pat. 215,335, May 26, 1908. Addition to Ger. Pat. 207,170, Feb. 2, 1908.

THE reaction described in the principal patent for preparing aromatic nitro-compounds by the use of the compounds of zinc or copper oxide with nitrogen oxides (this J., 1909, 360), can be utilised for the oxidation of anthracene, if carried out at high temperatures, e.g., 250°–350° C.; a stream of air or oxygen is passed through the reacting mixture, at ordinary or reduced or increased pressure. It is probable that a *meso*-nitro-dihydroanthranol is at first formed (as when anthracene is treated with nitrous gases in acetic acid solution) and the nitrogen is eliminated during the reaction.—T. F. B.

Vat [thioindigo] dyestuffs; Process for preparing —. Farbwerke vorm. Meister, Lucius, und Brüning. Ger. Pat. 216,224, July 23, 1908.

THIOINDIGO or halogen-derivatives of thioindigo are nitrated, and the products are treated with halogens or halogenating agents, or they may be first reduced and then halogenated. The dyestuffs dye from the vat, grey-black or violet-black shades, which are faster than those obtained with the dyestuffs produced by merely nitrating (or nitrating and reducing) thioindigo.—T. F. B.

Azoxybenzene and azobenzene; Process for preparing —. Farbwerke vorm. Meister, Lucius, und Brüning. Ger. Pat. 216,246, Oct. 1, 1907.

WHEN nitrobenzene is reduced by means of alkali sulphides in strong solutions of alkali hydroxide, only traces of aniline are formed, the product consisting of either azoxybenzene or azobenzene, according to the amount of sulphide used and the duration of the reduction. The yields of the two substances amount to 90 per cent. of the theoretical yield.—T. F. B.

Dianthraquinone oxides; Process for preparing —. Farbwerke vorm. Meister, Lucius, und Brüning. Ger. Pat. 216,268, Oct. 14, 1908.

WHEN hydroxyanthraquinones are heated with halogen derivatives of anthraquinone in presence of sodium acetate or salts of other weak organic acids, dianthraquinone oxides are produced. For example, the condensation of α -chloroanthraquinone with β -hydroxyanthraquinone furnishes α - β -dianthraquinone oxide, which is insoluble in water and in dilute acids and alkalis. These oxides may be used for the preparation of dyestuffs.—T. F. B.

Monazo dyestuff; Process for preparing a — insoluble in water. Act.-Ges. f. Anilinfabr. Ger. Pat. 216,417, July 1, 1908.

NITROCHLORO-*m*-ANISIDINE ($\text{OCH}_3 : \text{NH}_2 : \text{Cl} : \text{NO}_2 = 1 : 3 : 4 : 6$) is diazotised and combined with β -naphthol; an insoluble, orange dyestuff is produced, which is especially suitable for making lakes. These lakes, which are fast to light, can be prepared by effecting the combination in presence of alumina, barium sulphate, or other substratum.—T. F. B.

Monazo dyestuffs; Manufacture of —. A. G. Bloxam, London. From Act.-Ges. f. Anilinfabr., Berlin. Eng. Pat. 6086, March 13, 1909.

SEE Fr. Pat. 401,006 of 1909; this J., 1909, 1120.—T. F. B.

Colouring matters of the anthracene series; Manufacture of —. J. Y. Johnson, London. From Badische Anilin und Soda Fabrik, Ludwigshafen on Rhine, Germany. Eng. Pat. 7931, April 2, 1909.

SEE Twelfth Addition to Fr. Pat. 319,531; preceding.—T. F. B.

Azine dyestuff and process of making same. P. Ott, Leverkusen, Assignor to Farbenfabr. vorm. F. Bayer und Co., Elbertfeld, Germany. U.S. Pat. 940,354, Nov. 16, 1909.

V.—PREPARING, BLEACHING, DYEING, PRINTING AND FINISHING TEXTILES, YARNS, AND FIBRES.

Bleaching and dyeing works and cotton cloth printing works. Statutory Rules and Orders, 1909, No. 1370. [T.R.]

AN order has been issued, applying the provisions of Sec. 116 of the Factory and Workshop Act, 1901, with modifications, to bleaching and dyeing works, and works in which the printing of cotton cloth is carried on. The order relates to the furnishing of workers with particulars as to their work and wages, and to the penalties liable to be imposed for divulging trade secrets.

Chemicals for use in textile factories in Uruguay. Board of Trade J., Dec. 9, 1909. [T.R.]

THE "Diario Oficial" of Uruguay for the 28th October, contains a Decree adding "Gibet" glue, potassium sulphate and cyanide, and crystallised sodium sulphate to the list of articles which may be imported on payment of duty at the rate of 5 per cent. *ad val.* for use in washing and dyeing processes carried out in yarn and tissue manufactures.

PATENTS.

Nitrocellulose; New solvent for —, for the production of artificial threads, films, &c., J. M. Sauverzac. Fr. Pat. 402,950, Sept. 12, 1908.

THE nitrocellulose is dissolved in the solution of a metallic chloride in alcohol. A solution of 10 grms. of aluminium chloride in 100 c.c. of alcohol dissolves 50 grms. of nitrocellulose, and the mixture may be diluted with as much as 80 per cent. of water. The threads spun from this solution are said to be very supple and elastic. (See also Eng. Pat. 1858 of 1896; this J., 1897, 335.)—F. M.

Artificial silk; Apparatus for spinning — and "lustring" natural silk and other textile fibres. B. Loewe. Fr. Pats. 403,242 and 403,243, Sept. 18, 1908.

UPON a vertical frame a reservoir is mounted from which the cellulose solution is fed, under pressure, to a pipe carrying a number of spinnerets. The thread issuing from each spinneret is wound upon a bobbin to which a to and fro motion is imparted. Or, upon leaving the spinneret,

the thread may be led into a box, in the centre of the bottom of which there is a fine orifice, through which the thread is drawn and then wound upon the bobbin. When the bobbin is full, it is removed and the thread is drawn off through a bath in which the coagulation is completed, and wound upon a reel. In "lustreing" natural silk or other fibres, these are passed through a special form of spinneret, in which they are "sized," and traverse a similar spinneret in which they receive a coating of artificial silk, the covered threads being then treated as above described.—F. M.

Artificial silk; Improving the elasticity and resistance to water of —. J. Gebauer. Fr. Pat. 403,264, May 22, 1909.

The improvement consists in producing a thread of artificial silk and caoutchouc, the latter ingredient being subsequently vulcanised. A solution of caoutchouc may be added to the spinning solution, or the thread or tissue of artificial silk may be passed through the caoutchouc solution. Vulcanisation is carried out in the ordinary way with sulphur chloride.—F. M.

Artificial silk; Manufacture of "animal" —, and its applications. H. du Boistesselin and C. Gay. Fr. Pat. 403,193, May 21, 1909.

CASEIN or fish glue is dissolved in an excess of soda lye, and dilute hydrochloric acid is slowly added. Excess of acid is avoided and the product which is precipitated if filtered off, pressed and dissolved in water. The aqueous solution can be coagulated with strong acids, common salts or salts of iron and yields threads which are supple, unaffected by water, and possess the properties of natural silk. Incorporated with animal or vegetable fibres, the product is suitable for working up into artificial leather, and with the alkaline-earth yields products which are hard and capable of taking a high polish.—F. M.

Wool; Carbonisation of —. V. Floquet. Fr. Pat. 402,847, May 8, 1909.

By leaving the woollen material to soak for some time in the acid bath, before carrying out the process of carbonising proper, the disintegration of the vegetable matter is assisted. It is claimed that the effect is more energetic if an oxidising agent (hydrogen peroxide) be added to this acid bath, or if oxygen gas be passed through it during the period of immersion.—F. M.

Bleaching of textile materials. A. Margotin. Fr. Pat. 403,245, Sept. 18, 1908.

The invention relates to the bleaching of textile materials by means of potassium permanganate and of hydrogen or other peroxides and the subsequent action of sulphur dioxide on the material. The impregnation with the oxidising material takes place in the ordinary way, but the treatment with sulphur dioxide is carried out in an apparatus of special construction. This consists of a vertical cylinder provided with a removable cover for the admission of the textile material and with a manometer to register the pressure. A perforated pipe passes down the centre of the cylinder and is connected underneath the apparatus, by means of a three-way cock to (1), a supply of sulphur dioxide gas; (2), a vacuum pump; and (3), an air compressor. By means of a series of valves, the material placed in the cylinder can therefore be submitted to a partial vacuum and to an atmosphere of sulphur dioxide; finally the sulphur dioxide can be expelled from the apparatus by the admission of compressed air. The exhaust gases are made to pass through a tube in the side of the cylinder into a vessel containing an alkali solution to absorb the sulphur dioxide.—S. H. H.

Colouring yarns for the manufacture of carpets and other fabrics. J. Bright and Bros., Ltd., and R. E. Oldroyd, Rochdale. Eng. Pat. 15,341, July 1, 1909.

This invention relates to the production of two or more colours in the same yarn by dyeing. The yarn is first dyed one colour, then another colour is dyed over the first, and if necessary yet another colour is applied.

The dyed yarn is submitted in parts to the action of chemical agents which destroy one or more of the colours with which the yarn is dyed. This can be carried out by dipping, saturating or steaming the parts under different conditions. For example a yarn is dyed first scarlet with Erythrosin and then dark crimson by further dyeing with Azofuchsin. On treating the yarn now, in parts, with sodium hydrosulphite solution the Azofuchsin is destroyed. Also a suitable brown colour made up of red, blue and yellow dyestuffs may be discharged in different parts of the yarn to give a variety of shades; the red, blue and yellow dyestuffs may be separately discharged by suitable reagents.—S. H. H.

Half-dyeing apparatus. F. Bauer, West Orange, N.J. U.S. Pat. 938,738, Nov. 2, 1909.

The apparatus comprises a semi-cylindrical tank provided with a longitudinal rotating shaft mounted in bearings on the end walls of the tank. A cylindrical wire screen is mounted around the shaft, being connected, at its ends, to the latter by means of radial spokes. The wire cylinder which rotates within and close to the tank, has, in one side, a longitudinal door, through which a perforated drip-board can be inserted, so as to divide the cylinder into two compartments of approximately equal size.

—A. S.

Dyeing textile fabrics; Apparatus for —. E. de Journo. Fr. Pat. 403,013, May 13, 1909.

The dyeing is effected by projecting a jet of dye-liquor on to both sides of the cloth. The cloth passes from one batch to another over five small rollers arranged somewhat in the form of the letter W and situated above the dye-liquor in the dye-bath. The middle roller is contained in a small box which is connected with a centrifugal pump by means of a tube which proceeds vertically downwards through the dye-bath and then horizontally to the pump. The pump is also connected directly with the liquor in the dye-bath, and, further, by means of a pipe which is a continuation of the pipe proceeding from the box mentioned, it supplies dye-liquor to another receptacle placed directly over that box. This receptacle has a perforated bottom and is made to fit the contour of the cloth passing over the middle roller; the arrangement is similar to the ordinary humidifier. The dye-liquor passing through the perforations mentioned, penetrates the cloth on the roller and is held for a time by a concentric semi-cylindrical envelope placed under the roller, so that the latter revolves for a time in the dye-liquor, and the lower surface of the cloth is impregnated. The dye-liquor then proceeds to the pump and round again in circulation.—S. H. H.

Dyeing silk yarn; Apparatus for —. E. de Journo. Fr. Pat. 403,014, May 13, 1909.

The apparatus consists of a bath containing the dye-liquors in which, suspended from a series of rods, hang the skeins of silk or other textile material. These rods are rigidly connected to another series of rods directly below them, inside the separate series of skeins, and just above the dye-liquor. By means of mechanism these lower rods are caused to revolve during the dyeing operation and thus to "turn" the skeins which are being dyed; the lower rods revolve to a position above the first-mentioned rods and back again, carrying the skeins round with them, and ensuring an equal time of immersion of all parts of the skeins in the dye-liquor. The upper rods are placed in notches on a frame which is fixed over the dye-bath. Above this frame there is an arrangement to secure the transference of the skeins from one side of the dye-bath to the other. The upper part of this device consists of a rack and pinion and gear wheels which cause the whole arrangement to move from one side of the bath to the other. This upper part is connected by a chain to the lower arrangement, which consists of a chain running on cog-wheels over and at right angles to the rods which hold the skeins. Hooks are attached to the links of the chain and as the chain revolves, these hooks catch the rods carrying the skeins and carrying them along, deposit the

rods and skeins at the other side of the dye-bath. During the transference the "turning" of the sticks referred to above takes place. Thus the skeins are periodically lifted outside of the dye-liquor from one side of the dye-bath to the other and at the same time "turned."—S. H. H.

Chemical treatment of textiles mounted on bobbins; Apparatus for the —. T. Robatel, J. Buflaud et Cie. Fr. Pat. 493,148, May 18, 1909.

THE core of each bobbin is surrounded by a cylinder containing many slits throughout its length. The thread is wound on this cylinder, which can be readily removed from the bobbin, and the thread dried or after-treated apart from the bobbin. The bobbin, cylinder, and thread are placed in an enclosing bobbin which has perforated ends, and series of these bobbins are then placed on end vertically in the bath which contains the chemical with which it is intended to treat the threads. By a mechanical device the series of bobbins is caused to revolve so that each series moves in a different direction from its neighbour.

—S. H. H.

Dissolved substance for use in making artificial threads and the like; Process for the production of a —. P. Friedrich, Berlin. Eng. Pat. 7617, March 30, 1909. Under Int. Conv., March 30, 1908. Addition to Eng. Pat. 4104 of 1909, dated Feb. 19, 1908.

VII.—ACIDS, ALKALIS, SALTS, AND NON-METALLIC ELEMENTS.

Hypophosphoric, phosphorous, and hypophosphorous acids; Determination of — in presence of each other and of phosphoric acid. A. Rosenheim and J. Pinsker. Z. anorg. Chem., 1909, 64, 327–341.

HYPOPHOSPHORIC acid may be accurately titrated by permanganate, and it reacts also with uranyl nitrate solution, giving a yellow precipitate, according to the equation, $2\text{NaH}_2\text{P}_2\text{O}_7 + \text{UO}_2(\text{NO}_3)_2 = \text{UO}_2(\text{HPO}_3)_2 + 2\text{NaNO}_3$, but it is not affected by heating with iodine solution. Phosphorous and hypophosphorous acids, on the other hand, are oxidised both by permanganate and by iodine, but give no precipitate with uranyl salts. The following methods of determining these acids in the presence of each other are, therefore, available and have been found satisfactory. (a). *Hypophosphate and phosphite or hypophosphite.* Titration with uranyl nitrate is followed by oxidation with standard permanganate. (b). *Phosphite and hypophosphite.* The acids are oxidised by standard iodine or permanganate, and the total phosphate produced by oxidation with nitric acid is determined. (c). *Hypophosphate, phosphite, and hypophosphite.* The first is determined with uranyl nitrate solution and

the others as in (b). (d). *Phosphate, hypophosphate, phosphite, and hypophosphite.* The total phosphorus, as phosphate, is determined after oxidation with nitric acid; the last three acids are then oxidised in another portion by standard permanganate, in a third portion phosphite and hypophosphite are oxidised by iodine solution, and a fourth portion is titrated with uranyl nitrate solution. Representing the quantities of the

acids respectively by x , y , z , and t : $x = \frac{2l+2k-n}{2a_1}$, $y = \frac{n-2k}{a_2}$, $z = \frac{k+2m-2l-n}{a_3}$, and $t = \frac{2l+n-2m}{2a_4}$, where

$a_1 = 1/\text{H}_3\text{PO}_4$, $a_2 = 1/\text{H}_2\text{P}_2\text{O}_7$, $a_3 = 1/\text{H}_3\text{PO}_3$, $a_4 = 1/\text{H}_2\text{P}_2\text{O}_5$, $m = 2g_1/\text{Mg}_2\text{P}_2\text{O}_7$ (g_1 = weight of magnesium pyrophosphate obtained), $n = 5g_2/\text{KMnO}_4$ (g_2 = weight of permanganate required), $k = g_3/21$ (g_3 = weight of iodine required), and $l = q\text{S}/\text{P}_2\text{O}_5$ (S = c.c. of uranyl nitrate solution used; 1 c.c. = q grms. of phosphoric oxide). The oxidation by permanganate is effected by slightly acidifying an approximately $N/10$ solution of the salt with sulphuric acid, adding a few c.c. of $N/10$ permanganate, and heating to $80^\circ\text{--}90^\circ\text{C}$; any red colour remaining is removed by titrating with oxalic acid, and permanganate is then again added, and the warming and titration with oxalic acid are repeated, permanganate being added in decreasing quantities until oxidation is complete. In oxidising by means of iodine, a 10 per cent. solution of hydrochloric acid and a known volume of $N/20$ iodine solution are added to a measured volume of the liquid, the mixture is heated for 2–3 hours on the water-bath in a closed flask, and the excess of iodine is titrated with thiosulphate in the presence of sodium bicarbonate, after allowing the solution to stand for several hours.—F. SODN.

Alkali-metal bicarbonates. De Forcrand. Comptes rend., 1909, 149, 825–829.

DILUTE solutions of the normal carbonates of potassium, rubidium, and cesium were exposed to the air for some weeks; they were found to absorb carbon dioxide up to a limit corresponding to the formulæ,

Dilute solutions of the bicarbonates were boiled in silver vessels, the bulk of the liquid being kept constant. In the case of the potassium salt, after a week's boiling the liquor was concentrated and cooled, when crystals separated. The crystals had the composition corresponding to the formula, $5\text{K}_2\text{CO}_3, 7\frac{1}{2}\text{H}_2\text{O}, 4\text{KHCO}_3$, or $5(\text{K}_2\text{CO}_3, 1\frac{1}{2}\text{H}_2\text{O}), 4\text{KHCO}_3$, whilst the mother-liquor was of the same composition as that attained by the normal carbonate solution through absorption of carbon dioxide. The bicarbonates of rubidium and cesium rapidly lost all their excess carbon dioxide, and were converted into normal carbonates; but on continuing the boiling, they slowly absorbed carbon dioxide again, and on concentrating and crystallising, yielded crystals of the formulæ,

respectively. The latter salt, when kept for a day on the water-bath, loses water, and becomes converted into the compound, $5(\text{Cs}_2\text{CO}_3, 2\text{H}_2\text{O}), 2\text{CsHCO}_3$; this hydrate of the normal carbonate has not before been isolated, though the other three have. No compounds containing a number of molecules of bicarbonate equal to or in excess of those of the normal carbonate, comparable to the natural *natrons*, have yet been produced in this manner. The thermo-chemistry of these compounds indicates that they are all very unstable; it is probable that a series of similar compounds exists, the composition of which is determined by dilution, temperature, and perhaps the content of carbon dioxide of the atmosphere.

—J. T. D.

Calcium silicides, and their capacity for absorbing [atmospheric] nitrogen. A. Kolb and R. Formhals. *Z. anorg. Chem.*, 1909, **64**, 342—367.

By melting together metallic calcium and pure silicon in an atmosphere of hydrogen, two silicides have been obtained, to which the formulae, $\text{Ca}_6\text{Si}_{10}$ and $\text{Ca}_{11}\text{Si}_{10}$, are assigned (compare Tamaru, this J., 1909, 526 and Hackspill, this J., 1908, 684); the powdered compounds were purified by washing with sugar solution at 0°C. and then with a little cold water. The former substance is obtained as bluish grey, very hard crystals, melting at about 1200°C.; it readily reacts with the halogens and, as a powder, burns when heated in the air; it is attacked with difficulty by cold water, but hot water, dilute alkalis, acetic acid, and hydrochloric acid decompose it with the liberation of hydrogen; it is scarcely affected by lime-water. When boiled with hydrochloric acid in the absence of light and in a current of carbon dioxide, a yellow crystalline silicone, $\text{Si}_{10}\text{H}_{10}\text{O}_8$, is obtained, which is very unstable when dry and is decomposed by boiling with water or alkalis, though fairly stable in the presence of acids; light converts it into a colourless "leucone." The second silicide is a crystalline powder, readily decomposed by boiling water, dilute acetic acid, or hydrochloric acid, which gives a white or pale yellow silicone, $\text{Si}_8\text{H}_7\text{O}_{13}$ or $\text{Si}_8\text{H}_8\text{O}_{13}$. Both silicides absorb nitrogen on heating, and very stable compounds are formed, special interest attaching to the reaction as providing a new method of utilising atmospheric nitrogen. With the compound, $\text{Ca}_6\text{Si}_{10}$, rapid absorption begins at 1010°C. and the temperature suddenly rises by 80°—100°C.; powdering the product and repeating the treatment gives a white substance, containing 26.73 per cent. of nitrogen (determined as ammonia by fusion with alkali) and smelling faintly of ammonia. The reaction takes place apparently according to the equation, $\text{Ca}_6\text{Si}_{10} + 14\text{N} = 2\text{CaSi}_2\text{N}_3 + 2\text{Ca}_2\text{Si}_2\text{N}_4$. The product is very slowly decomposed by boiling water with the liberation of ammonia. The second silicide behaves in a very similar way, but the reaction with nitrogen, which is probably represented by the equation, $\text{Ca}_{11}\text{Si}_{10} + 10\text{N} = \text{Ca}_{11}\text{N}_{10}\text{Si}_{10}$, is less vigorous; the product is dark grey and contains 14.84 per cent. of nitrogen; it is slowly decomposed by water, and completely by hydrochloric acid, giving a greenish-yellow silicone, according to the equation, $\text{Si}_{10}\text{Ca}_{11}\text{N}_{10} + 24\text{H}_2\text{O} = \text{H}_6\text{Si}_{10}\text{O}_{13} + 10\text{NH}_3 + 11\text{CaO} + 12\text{H}$. The nitrogen compounds are said to act as valuable manures and exert no poisonous action; they constitute an economical source of nitrogen in the soil, the nitrogen being liberated very slowly. Sodium cyanide may be obtained by fusing these compounds with sodium carbonate or with a mixture of sodium carbonate and carbon.

—F. SOEX.

Stannic acid; Isomerism of —. W. Mecklenburg. *Z. anorg. Chem.*, 1909, **64**, 368—374.

THE author explains the existence of isomeric *a*- and *b*-stannic acids by regarding these as colloidal modifications of hydrated stannic oxide, differing from each other in the size of their particles, and each retaining its individuality in the coagulated state. *a*-Stannic acid is believed to consist of relatively small and *b*-stannic acid of relatively large particles, and this view is supported by the fact that the *a*-acid has a greater adsorptive power than the *b*-acid and is more reactive; also, when stannic acid is prepared from colloidal tin solutions, the *a*-acid is always obtained, and this readily enters into colloidal solution again, whereas the *b*-acid is more readily precipitated from colloidal solution than the *a*-acid. The supposed salts of *b*-stannic acid are looked upon as hydrated stannic oxide containing adsorbed acids or alkalis.—F. SOEX.

Mercurous chloride; Duty on — in Switzerland. Board of Trade J., Dec. 2, 1909. [T.R.]

THE import duty on mercurous chloride has been fixed at 10 frs. per 100 kilos.

Salt for use in zinc chloride factories; Exemption of — from excise duty in the Netherlands. Board of Trade J., Dec. 2, 1909. [T.R.]

A DUTCH Royal order, dated Nov. 5, 1909, grants, under certain conditions, exemption from excise duty in the case of salt for use in zinc chloride factories.

PATENTS.

Alkalis and salts; Simultaneous electrolytic manufacture of —. C. A. Girard. Fr. Pat. 493,360, May 26, 1909.

A SOLUTION of an alkali or alkaline-earth salt, more or less concentrated, is electrolysed in a vessel forming a diaphragm, the latter containing also a soluble anode which, by solution, forms the required salt. The diaphragm is placed in an outer vessel containing water, in which the negative pole, consisting of a metallic plate unattacked by alkalis, is immersed. Instead of a soluble metal, ores, treated or not, may be used as the anode, and may be conductors or non-conductors of electricity, but in the latter case the ore is contained in a vessel which is itself a good conductor of electricity.—B. N.

Lead oxide; Manufacture of —. W. Eckford, Rhyl, Wales. Eng. Pat. 26,257, Dec. 4, 1908.

To prevent the escape of minute particles of lead oxide into the atmosphere during manufacture, separate closed melting and settling chambers are employed, which are connected by inlet and outlet pipes. A fan placed between the chambers draws the air and "floury" lead oxide over into the settling chamber, where most of the latter settles, the air returning to the melting chamber by means of the second connecting pipe. A small fan is used for withdrawing air from the settling chamber to produce and maintain a slightly reduced pressure within the apparatus and prevent leakage of the fine lead oxide. Means are provided for replenishing the air when necessary.—F. R.

Burning lime; Process of —, and apparatus therefor. H. L. Doherty, New York. U.S. Pat. 938,587, Nov. 2, 1909.

IN the process of calcination of limestone, a portion of the gases evolved is mixed with air which has been heated by a portion of the heat of the gases, and the mixture is converted into producer gas in a producer charged with carbonaceous fuel. The producer gas is mixed with another portion of the gases produced in the calcination, and the mixture is burnt in contact with the incandescent lime by means of air which has been heated by using it for cooling the burnt lime. The composition of the mixture of producer gas and calcination-gases is so regulated that the temperature developed on burning is not sufficient to cause the impurities present in the limestone to combine chemically with the lime.—A. S.

Potassium salts present in the residual liquors (calcium tartrate mother liquors) from the manufacture of tartaric acid; Process of extracting —. A. Alberti. Fr. Pat. 492,925, May 10, 1909. Under Int. Conv., May 14, June 25, and Aug. 12, 1908, and April 9, 1909.

THE process is for the recovery of the potassium chloride and sulphate contained in the calcium tartrate mother liquors obtained in the manufacture of tartaric acid. The liquor is treated with excess of lime, filtered, and transferred to suitable vats, in which it is agitated with bleaching powder, or with chlorine in the presence of a base (lime), for some hours, in order to oxidise most of the organic matter present, the quantity of hypochlorite required being established by a preliminary experiment with permanganate. When the liquor is decolorised, the precipitated calcium carbonate and sulphate are removed by filtration, and the liquor, after neutralisation with hydrochloric acid, is concentrated in some form of continuous vacuum evaporator, and the potassium salts recovered by crystallisation.—K. SOEX.

Burnt pyrites; Process for separating from — most of the heterogeneous materials present, so as to render it soluble in sulphuric acid of 52° B., with the object of preparing ferrous sulphate and separating any contained copper. A. Pezzolato. Fr. Pat. 402,939, May 12, 1909. Under Int. Conv., May 14, 1908.

Burnt pyrites, mixed with about 2 per cent. of charcoal, is heated to a red heat and cooled out of contact with air; it then acquires the property of being attracted by a magnet, and the whole of the iron may be extracted by a magnetic separator, in a form such that it dissolves in sulphuric acid (52° B.) to give ferrous sulphate. Any ferric sulphate formed during the action is reduced by acidifying the solution and adding metallic iron, which serves to concentrate the solution and precipitate any copper that may be present. An excess of carbon must not be used.—F. SODX.

Sodium-alum free from iron; Process for the preparation of —. F. O. Kauffmann. Ger. Pat. 216,934, Oct. 22, 1905.

AN excess of solid powdered sodium sulphate or bisulphate is added, at 25°–50° C., to a faintly acid solution of aluminium sulphate of sp. gr. at least 1.25, and the pulverulent sodium alum produced is separated in a centrifugal machine. Or, solid aluminium sulphate may be added to a concentrated solution of sodium bisulphate or sulphate. Crystalline sodium-alum may be obtained directly from the hot concentrated solution containing excess of sodium sulphate, by cooling it rapidly so as to produce a supercooled solution. From the latter the sodium-alum separates directly as crystals, without forming the amorphous magma obtained in the ordinary crystallisation process.—A. S.

Shaving cream [depilatory]; Process for the preparation of a —. J. Lütje. Ger. Pat. 216,250, Nov. 25, 1908.

A MIXTURE of a sulphide of an alkali or alkaline-earth metal with starch and water is heated until the starch is gelatinised. The product is stated to remove hair without having any irritating effect on the skin.—A. S.

Hydrogen cyanide and cyanogen compounds; Process for the preparation of —. C. Beindl. Ger. Pat. 216,264, Aug. 12, 1908.

HYDROGEN cyanide or other cyanogen compounds are produced by passing a mixture of a gaseous nitrogen compound, e.g., ammonia, and a gaseous hydrocarbon, either alone or in presence of nitrogen or hydrogen, or of a mixture of the two, over a contact substance. The essential feature of the process is the use of a contact substance of wire gauze or other similar form. Various metals may be used as contact substances. The temperature required varies with the nature of the contact substance and with the nature and velocity of the reacting gases. With copper gauze as catalyst, cyanogen is formed at 480° C., from a mixture of acetylene and ammonia.—A. S.

Carbide and method of manufacturing same. H. L. Hartenstein, Constantine, Mich., Assignor to Continental Investment Co., Duluth, Minn. U.S. Pat. 938,581, Nov. 2, 1909.

THE improvement claimed consists in partially cooling, and solidifying, a portion of the mass of molten carbide produced in the usual manner, and then building up a block or ingot by successive additions to the portion first solidified. The carbide is agitated whilst it is being cooled.—A. S.

Hydrogen peroxide solution; Process for the preparation of pure —. O. Dony-Hénault. Fr. Pat. 403,294, May 24, 1909.

SODIUM peroxide is mixed with dilute sulphuric acid, containing 4–5 per cent. of alcohol, in a vessel of earthenware, glass, or lead, fitted with a stirrer and cooling

worm; a further quantity of alcohol is then added (e.g., so as to bring the total to 35 per cent.), and the temperature is reduced to about –10° C., which causes almost complete deposition of the sodium sulphate present; the solution is separated from the crystals by decantation and the use of a filter-press, the plates of which are cooled by internal circulation of a refrigerating material; finally the alcohol is removed by distillation *in vacuo* at 30°–40° C. in glass or lead retorts. This process allows the direct production of concentrated solutions of hydrogen peroxide, and the yield is almost theoretical, since the peroxide is remarkably stable in the medium employed for the decomposition. Sodium peroxide is superior to barium peroxide for the purpose, in that it is purer, and contains double the proportion of active oxygen; also its decomposition by sulphuric acid is instantaneous and complete. The percentage of salts in the finished product is no higher than when barium peroxide is used.—F. SODX.

Hydrogen peroxide solutions; Process for rendering stable. E. Merck. Ger. Pat. 216,263, Apr. 27, 1909. Addition to Ger. Pat. 203,019, Nov. 7, 1907 (this J., 1908, 1204).

THE slight solubility of uric acid, which is used as a preservative for hydrogen peroxide solutions, is a disadvantage in some cases: it is now proposed to utilise barbituric acid, which is much more soluble, and which has the same preservative properties as uric acid.

—T. F. B.

Hydrogen; Production of —. Consortium für Elektrochem. Ind. Ges. m. b. H., Nürnberg, Germany. Eng. Pat. 21,032, Sept. 14, 1909. Under Int. Conv., Nov. 9, 1908.

BY the addition of lime, or calcium compounds that form lime, nearly the full theoretical quantity of hydrogen is rapidly liberated on heating silicon in an aqueous solution of caustic alkali. The process may be carried out in an iron generator fitted with stirrers.—C. J. G.

Bicarbonate of soda; Manufacture of —. D. Peniakoff, Brussels. Eng. Pat. 6115, March 15, 1909.

SEE Fr. Pat. 400,241 of 1909; this J., 1909, 1034.—T. F. B.

Ammonia; Production of —. F. W. Frerichs, St. Louis, U.S.A. Eng. Pat. 23,889, Nov. 7, 1908.

SEE U.S. Pat. 905,415 of 1908; this J., 1909, 21.—T. F. B.

Ammoniacal solution of cupric oxide; Process for the production of a permanent —. Chem. Fabr. Bettenhausen Marquart und Schulz, Cassel-Bettenhausen, Germany. Eng. Pat. 4872, Feb. 27, 1909. Under Int. Conv., March 25, 1908.

SEE Fr. Pat. 399,911 of 1909; this J., 1909, 938.—T. F. B.

Salts derived from the alkaline, alkaline earthy, and earthy peroxides; Process for the manufacture of —. G. F. Jaubert, Paris. Eng. Pat. 7633, March 30, 1909. Under Int. Conv., April 29, 1908.

Extracting ammonium sulphate from distillation gases. Fr. Pat. 403,050. See 11.

VIII.—GLASS, POTTERY, AND ENAMELS.

PATENTS.

Clays, porcelain earth and the like or mixtures thereof; Process for making slip from —. E. Weber, Schwepnitz, Saxony. Eng. Pat. 6560, Mar. 18, 1909.

IN order to render liquid by the addition of alkalis, those clays and earths which tend to gelatinise, and in which

the addition of humic acid or the like is not effectual. sufficient lime, or barium oxide, peroxide, hydroxide, or carbonate, or other suitable material, is added to render the interfering sulphate or carbonates insoluble. For example, 450 kilos. of a dry mixture of a fat refractory (Stourbridge) clay and coarse chamotte (fireclay) material with 350 grms. of barium hydroxide, 120 litres of water, and 600 grms. of caustic soda form a mass which can be readily cast.—F. R.

Ceramic objects, especially cooking utensils; Process for obtaining adherent conducting deposits on —. S. Heller and C. Baumgertl. Fr. Pat. 493,074, May 15, 1909.

THE articles are coated with a mixture of an alcoholic solution of celluloid, tar, unsaturated hydrocarbons, and a salt of gold absorbed in graphite, and are then fired in a muffle.—W. C. H.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

PATENTS.

Wood; Process and apparatus for the impregnation of —. Pagès, Camus et Cie., and P. Bardy. Fr. Pat. 403,022, Sept. 14, 1908.

THE pores of the wood are opened, and the sap is removed, by heating the wood in vapours or gases which contain solvents, for wood oils, such as formaldehyde and acetone, and render these oils soluble in the impregnating liquids. The impregnating liquids are then forced into the wood under pressure and at a high temperature. In the case of creosoting, the wood is heated in a current of wood-gas containing ketones and aldehydes, then in a current of vapour of light wood-oils or some similar product, and finally impregnated, under pressure, with hot heavy wood oils. The light and heavy wood oils may be replaced by light and heavy coal-tar oils. The process is carried out in a closed vessel provided inside with a grid, and also with inlets and outlets, controlled by suitable cocks, for the gases, the light products, and the heavy products which constitute the actual impregnating substances.—W. C. H.

Cement-kiln. T. A. Edison, Orange, N.J. U.S. Pat. 939,817, Nov. 9, 1909.

CERTAIN of the sections which form a rotary cement-kiln, are provided at the ends with flanges extending outwards, which engage and form a loose fit with other flanges extending inwards from a stationary casing surrounding the kiln at one or more of the sections. Water is sprayed on to the kiln inside the casing, the excess passing off through a trap at the bottom. Any steam generated in the casing is removed by means of a fan, which also induces a current of air through the loose joints between the kiln and the casing.—W. C. H.

Composition for paving, flooring, and like purposes; Making a — and method of laying same. J. H. Amies, Philadelphia, U.S.A. Eng. Pat. 9929, April 27, 1909. SEE U.S. Pat. 929,813 of 1909; this J., 1909, 984.—T. F. B.

Paving brick or block; Vitrified —. K. Langenbeck, Boston, U.S.A. Eng. Pat. 13,091, June 3, 1909.

X.—METALS AND METALLURGY.

Special steels. L. Guillet. Int. Congr. for Testing of Tech. Materials, Copenhagen, 1909. Z. Elektrochem., 1909, 15, 893—894.

SPECIAL or alloy steels can be conveniently arranged in four groups according to their importance, viz., (1) Nickel and nickel-chromium-steels; (2) vanadium-steels;

(3) silicon-containing steels, also called manganese-silicon-steels; and (4) tungsten-steels. Only those possessing a pearlitic structure corresponding to that of ordinary carbon steel, are available for general use. The objects sought in the manufacture of these alloy steels are first, improvement in mechanical properties, remarkably illustrated by the use of vanadium (of which 0.2 to 0.3 per cent. suffices to increase very materially the tensile strength and elastic limit of the steel), and in a less degree by use of silicon and chromium; and second to simplify the heat treatment, by rendering less rigid the requirements as to maintenance of exact temperatures and conditions of cooling. A nickel-vanadium-steel, for instance, containing nickel 7, vanadium 0.2, carbon 0.2, and manganese 0.3 per cent., needs only a single hardening in water from a very wide temperature-range. Many nickel-steels can be treated by air-cooling alone—steels showing martensitic structure are especially suitable for this treatment. The following are examples of the composition of such air-hardening steels:—

Carbon.	Nickel.	Chromium.	Manganese.	Silicon.
per cent.	per cent.	per cent.	per cent.	per cent.
0.75	3.82	1.28	0.52	0.17
0.252	5.43	0.52	0.33	0.22
0.366	4.76	0.92	0.41	—

Where the steel has to withstand much friction, a high carbon-content is desirable, though chromium in a lesser degree exhibits the same tendency. The best results are in general obtained with steel containing 0.4 per cent. of carbon, though with silicon steels the carbon may be advantageously raised to 0.6 per cent. J. T. D.

Iron; Retardation of the acidation of — by chromium trichloride. P. Rohland. Z. Elektrochem., 1909, 15, 865—866.

CHROMIUM chloride solution greatly retards the rate of oxidation of iron; this protective action is exercised in presence of acetic acid, but not when a highly dissociated acid, such as hydrochloric, sulphuric, nitric, or oxalic acid is added. In a mixed solution of sodium, potassium, or calcium chloride with chromium chloride, iron is still protected, but oxidation occurs in a solution of ferric chloride and chromium chloride. In the presence of sulphates, chromium chloride exerts a protective action, but not in the presence of nitrates. Similar protective action is exerted by chromates or bichromates; and iron, in its turn, exerts a similar influence on the rate of oxidation of copper. The protective effect of chromium compounds is possibly due to a temporary deposition of metallic chromium on the iron. The author gives an explanation of the foregoing results in accordance with the theory of electrolytic dissociation.—J. T. D.

Copper; Requirements to be satisfied by — for its technical applications. L. Guillet. Int. Congr. for Testing of Technical Materials, Copenhagen, 1909. Z. Elektrochem., 1909, 15, 897.

THE author summarises the replies received from members of the Commission on this subject. As far as the mechanical properties of the metal are concerned, a small content of arsenic is said to be advantageous, whilst silver, cadmium, zinc, silicon, lead, phosphorus, and less than 0.1 per cent. of oxygen are not harmful. Bismuth, antimony, nickel, tellurium, and sulphur must be avoided. With regard to electrical conductivity, bismuth, antimony, sulphur, and oxygen are not of great moment, but arsenic and phosphorus are very injurious. Even for its electrical uses, however, the mechanical properties of the metal are of at least as great importance as its purely electrical ones. For further research, an improvement in the method of determining oxygen in copper is greatly to be desired; it may make considerable difference whether oxygen be present as cuprous oxide or carbon monoxide. The influence on the metal of various gases also requires to be investigated.—J. T. D.

Colloidal solutions: Preparation of — by disintegration of metals by means of ultra-violet rays. T. Svedberg. Ber., 1909, 42, 4375—4377.

THE author has succeeded in preparing colloidal solutions of metals by the application of the observation of Lenard and Wolf (Ann. Phys. Chim., 1889, 37, 443) that certain substances, especially metals, are dis-integrated when exposed to ultra-violet rays. Pieces of metal, the surfaces of which had been carefully freed from oxide, were placed in a shallow dish containing a dispersion-medium, and exposed to the rays from a Heraeus quartz mercury arc lamp placed a few centimetres above. After a few minutes colloidal solutions were obtained from silver, copper, tin, and lead, but platinum, aluminium, and cadmium remained practically unaffected. The action was especially marked in the case of lead, which yielded a colloidal solution in ethyl alcohol, and a milky liquid, probably containing colloidal lead hydroxide, in water. Experiments with silver and lead in water, ethyl alcohol, isobutyl alcohol, ether, acetone, ethyl acetate, and amyl acetate showed that the nature of the dispersion-medium had a great influence on the results. It is possible to prepare solutions by this method, the colloidal particles of which are very small, and of practically uniform size.

—A. S.

Aluminium-copper alloys: Electrical properties of — W. Broniewski. Comptes rend., 1909, 149, 853—855.

THE author has determined, for a series of 22 aluminium-copper alloys of composition varying from 100 per cent. of aluminium to 100 per cent. of copper, the specific conductivity, the temperature-coefficient of resistance, the thermo-electric power compared with copper between 0° and 100° and 0 and -80° C., and the electromotive force, with respect to a carbon electrode depolarised by manganese dioxide in a saturated solution of ammonium chloride. All the determinations, except those of electromotive force, were made on chilled and annealed specimens of each alloy. The curves plotted from the tables of results indicate the existence of four compounds, having the formulae, Al_2Cu , AlCu , Al_2Cu_3 , and AlCu_3 ; the third of these has not before been indicated. Annealing, in the case of most of the alloys, increases their conductivity, but reduces that of the compound, AlCu_3 , by half; the change occurs at a temperature above 500° C., and is possibly due to the polymerisation on cooling of the variety stable at a high temperature into a variety stable at the ordinary temperature and of higher specific resistance.—J. T. D.

Mineral production of Tasmania. Board of Trade J., Dec. 2, 1909. [T.R.]

THE following figures show the mineral production of Tasmania during the years ended 30th June, 1908 and 1909:—

	1907-8.		1908-9.	
	Quantity.	Value.	Quantity.	Value.
Gold .. ozs.	65,436	277,957	48,406	205,619
Silver-lead ore .. tons	68,107	450,348	77,463	230,125
Blister copper ..	8,715	650,359	8,845	608,535
Copper and copper ore ..	659	11,483	1,783	17,074

Total value	—	1,902,810	—	1,616,390

Gold and silver production of the United States. U.S. Geol. Survey, 1908. [T.R.]

THE production of gold in the United States in 1908 was 4,574,340 fine oz. valued at \$94,560,000 and the pro-

duction of silver was 52,440,800 fine oz., with the commercial value (at the average price for the year) of \$28,030,600. As compared with the figures for 1907, the above shows an increase in the gold product of \$4,124,300 and a decrease in the silver product of 4,073,900 fine oz.

Air for metallurgical operations: Diccication of —. L. Sterne, London. From L. Block, New York. Eng. Pat. 23,529, Nov. 3, 1908.

IN an apparatus for the removal of moisture from the air blast used in blast-furnaces, by first compressing the air to an extent considerably in excess of that required for the blast and subsequently cooling it, and allowing it to expand (see Eng. Pat. 24,647 of 1905; this J., 1907, 206), a preliminary drying is now effected. The incoming air is caused to pass through pipes arranged within the chamber in which the previously compressed air is allowed to partially expand, the resulting cooling causing the deposition of a considerable proportion of the water contained in the air before the latter enters the compressors.

—F. R.

Iron: Process and apparatus for the introduction of solid reducing agents into molten slag floating on molten —. O. Tichl. Ger. Pat. 213,479, April 10, 1908.

IN order to protect the reducing agent from the oxidising action of the furnace-gases, whilst it is being introduced into the molten slag (containing iron oxide) floating on the molten iron, some molten slag is introduced at the same time, so as to form a protecting layer above the reducing agent. For this purpose, the inlet pipe is provided with a pipe for the introduction of the reducing agent in addition to the funnel through which the molten slag is introduced.—A. S.

Calcium-silicon alloys, etc.: Method of manufacturing —. H. Goldschmidt and O. Weil, Assignors to T. Goldschmidt, Essen on Ruhr, Germany. U.S. Pat. 938,758, Nov. 2, 1909.

THE content of alkaline-earth metal in alloys of the same with silicon can be increased by melting the alloys with iron. The process is specially useful for increasing the calcium content of calcium-silicon alloys.—A. S.

Antimony sulphide ores: Treatment of — for the production of metallic antimony, its oxides, sulphides, and oxysulphides. A. Germot. First Addition, dated Sept. 7, 1908, to Fr. Pat. 379,143, June 22, 1907 (this J., 1907, 1204).

A PART or the whole of the blast of air or oxygen (*loc. cit.*) is directed on the surface of the molten ore, to which, also, antimony oxide produced in previous operations is added.—J. W. H.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

(A.)—ELECTRO-CHEMISTRY.

Lead accumulator-plates; Rapid formation of —. G. Just, P. Askenasy, and B. Mitrofanoff. Z. Elektrochem., 1909, 15, 872—892.

SMOOTH lead plates were first formed in pure sulphuric acid by Planté's method, their rate of increase of capacity and curves of charge and discharge being determined during the course of the process. Similar plates, formed in acid to which potassium nitrate had been added, showed a much more rapid rise of capacity, and a change in the form of the curves of charge and discharge. As the concentration of the nitrate was increased, the coating showed a greater tendency to fall away from the plate; having regard both to this tendency, on the one hand, and to the increased rapidity of formation on the other, an acid containing 218 grms. of sulphuric acid and 30 grms. of potassium nitrate in the litre is most advantageous. When nitrate is used, the first effect is the formation of a white coating of lead sulphate on the positive plate; this is thinner and more adherent, and is sooner converted completely into peroxide, according as the nitrate-concentration is lower. Attempts to prevent the scaling-off of the formed coating with high nitrate-concentration were unsuccessful. With grooved or cellular plates, higher nitrate-concentrations could be used, and capacities suitable for technical use attained very rapidly, whilst the coatings were still sufficiently adherent and durable.

J. T. D.

PATENTS.

Insulating layers of oxide or hydroxide; Production of — on polished metallic wires. Spezialfabrik für Aluminium-Spulen und -Leitungen Ges.m.b.H. Fr. Pat. 403,234, May 22, 1909. Under Int. Conv., Feb. 5, 1909.

THE metallic wire or ribbon, in the form of bundles, or wound on bobbins, is introduced into a liquid capable of bringing about oxidation, and the material is afterwards dried artificially or by exposure to air. The air contained in the interior of the bobbins is rarefied, and the oxidising liquid forced into the bobbins by an increase of pressure.—B. N.

Electrodes; Manufacture of — composed of oxides, or electrode masses with great internal cohesion, for primary and secondary elements. R. Pörsche. Fr. Pat. 403,276, May 24, 1909.

THE process consists in the application of the thermite process to the production of electrodes. An oxide, such as copper oxide, is mixed with a finely-divided metal such as iron or aluminium, and heated to incandescence. The oxide yields oxygen to the finely-divided metal, and the heat which is developed during the action produces a sintering of the oxides, and a partial welding of the metal. The oxide formed is removed by appropriate

treatment, e.g., by the aid of the electric current in an alkaline electrolyte or by the action of mineral acids, thus producing a porous electrode. The lower oxide or the metal which remains after disengagement of oxygen, may be afterwards completely reoxidised by heating or by the action of the electric current. In a variation of the process, the oxide formed by the action of oxygen on the finely-divided metal is left in the finished electrode, and only the oxide supplying the oxygen, or the reduced metal, is removed by appropriate means.—B. N.

Electric furnace for the treatment of gases. Salpetersäure-Ind. Ges.m.b.H. Ger. Pat. 216,090, Aug. 26, 1908.

THE apparatus is shown in the accompanying figure. Besides the two chief electrodes, 7 and 8, auxiliary electrodes, 2, 3, are provided, which do not quite meet at their upper ends, but are connected below by a conductor, 4, and a resistance, 5. Streams of the gas to be treated are forced in through the nozzles, 11, 12, in order to assist the electro-dynamic action, and carry upwards the flames produced between the two pairs of electrodes, until they unite to form the long stable flame, 13, 15. The main quantity of the gas to be treated enters through the openings, 16, 17, and the reaction-products leave through 18. Should the flame, 13, 15, be quenched during working, flames are again produced between the inner and outer electrodes, and these rise and form another stable flame.—A. S.

Mica; Process for softening —. Siemens-Schuckert Werke Ges.m.b.H. Ger. Pat. 216,404, March 20, 1908.

NATURAL mica is frequently too hard to be used for various purposes in electrical apparatus. According to the present patent it is softened by packing it in layers between metal plates in a metal box, heating it to a relatively low temperature, and then quenching in water.—A. S.

Insulating media; Process for producing transparent, flexible, infusible —. K. Winkler, Zürich, Switzerland. Eng. Pat. 24,597, Nov. 16, 1908. Under Int. Conv., Nov. 18, 1907.

SEE Ger. Pat. 208,753 of 1907; this J., 1909, 529.—T. F. B.

Electrolyte for use in electric batteries. W. J. L. Sandy, London. U.S. Pat. 940,734, Nov. 23, 1909.

Electrolytic manufacture of alkalis and salts. Fr. Pat. 403,360. See VII.

(B.)—ELECTRO-METALLURGY.

PATENTS.

Iron oxide scale; Electrolytically removing —. C. W. Danforth and N. Jones, Sharon, Pa. U.S. Pat. 939,223 and 939,224, Nov. 9, 1909.

THE iron or steel is subjected to the action of an electric current, the density of which is not less than seven amperes per square foot, whilst immersed in an electrolyte consisting of a solution, in water or dilute sulphuric acid, of an alkali bisulphate at a temperature of not less than 40° C.—B. N.

Metals; Process for extracting and refining — J. H. Reid. Fr. Pat. 403,033, May 11, 1909. Under Int. Conv., Sept. 23, 1908.

THE mineral or material to be treated is mixed with a reagent which forms, with the metals to be extracted, compounds from which the metals can be recovered by electrolytic deposition. This mixture is allowed to fall down a vertical column consisting of chambers provided with electrodes and forming a vertical series of electric arc furnaces. The temperature of each chamber corresponds with the point of volatilisation of a compound contained in the mixture or produced therein as the material falls. The vapours given off in each chamber are withdrawn by means of pipes into condensing vessels containing water. The contents of the condensers are treated electrolytically for the separation of the metals.

—J. W. H.

Furnace; Electric induction — A. Hiorth. Fr. Pat. 403,038, May 14, 1909. Under Int. Conv., May 15, 1908.

THE furnace comprises a bath of metal, in the form of two circular channels united at one side, forming the secondary, with two vertical limbs of an iron core passing through the circular channels. The primary of the furnace consists of four bobbins in the form of discs surrounding the vertical limbs, two being placed below, and two suitably suspended above the circular channels. The furnace is mounted on a pivot, so as to be oscillating in character, whilst the core of iron is fixed and mounted independently of the furnace. —B. N.

Zinc; Process and apparatus [electric furnace] for the extraction of — from its ores. A. L. J. Queneau. Fr. Pat. 403,048, May 14, 1909.

THE process consists in using a rotary electric furnace, into which the ore, previously heated and mixed with a reducing agent, is charged. The furnace consists of a cylindrical iron casing lined with refractory material and provided with annular rings for support and an annular gear wheel for rotation. Each end of the furnace is provided with an annulus of graphite blocks by which the current is carried to the contents of the furnace. A fluid resistor of any convenient substance (*e.g.*, iron) and of suitable volume is charged into the furnace on commencing work. Condensers for the zinc are fixed to the end covers of the furnace and rotate with it. —J. W. H.

XII.—FATTY OILS, FATS, WAXES, AND SOAPS.

Fats; Melting and solidifying points of — 1., *Binary mixtures and II., ternary mixtures of stearic, palmitic, and oleic acids.* E. Carlinfanti and M. Levi-Malvano. *Gaz. chim. ital.*, 1909, 39, II., 353–385.

THE authors have applied the methods used in the thermal examination of metallic alloys to mixtures of fatty acids, using an apparatus similar to that employed for cryoscopic determinations. The oleic acid used in the experiments had the iodine value, 90.5. The results obtained are given in tables and curve-diagrams. In the case of mixtures of stearic and palmitic acids, the fusion-curve shows a distinct "break" at a point corresponding to a mixture of equimolecular proportions of the two acids and a temperature of 56° C. The whole curve may thus be divided into two portions. The first corresponds to mixtures of stearic acid and the addition-compound, $C_{18}H_{36}O_2$, $C_{16}H_{32}O_2$; this is a smooth curve, the mixtures solidifying as a series of solid solutions. The second portion, corresponding to mixtures of the addition-compound and palmitic acid, shows a maximum at 56.25° C. (about equal parts by weight of palmitic and stearic acid) and a minimum at 54.75° C. (about 70 per cent. of palmitic acid), but as neither of these points corresponds to a mixture of the two acids in stoichiometrical proportions, the authors conclude that the addition-compound and palmitic acid form three different series of solid solutions. Mixtures of stearic and oleic acids and of oleic and palmitic acids give smooth fusion-

curves, indicating the formation, in each case, of a simple series of solid solutions. Starting from pure stearic acid or palmitic acid, the solidifying point falls at first slowly and then more rapidly on addition of oleic acid, the curves being markedly convex. In the case of mixtures of the three acids—stearic, palmitic, and oleic—the temperature rises by 1°–1.5° C. when the fused mixture begins to solidify, and then falls, slowly until solidification is complete, and more rapidly afterwards. In no case is there any retardation of the rate of cooling; hence only one solid phase, consisting of a solid solution of the three acids, is present. The solidifying points (beginning of crystallisation) of 50 ternary mixtures of the three acids in different proportions are shown in the following table:—

Stearic acid.	Palmitic acid.	Oleic acid.	Solidifying point.
Per cent.	Per cent.	Per cent.	° C.
74.5	13	12.5	62.30*

5.5	77.5	19.5	54.85*
8	66	26	52.40*
20	30.5	49.5	44.55*

These results are given graphically in an equilateral triangle, the three corners of which represent the three acids, and isothermal curves are traced within the triangle. With the aid of such a diagram the composition of a mixture of the three acids can be ascertained directly, in most cases, if the solidifying point and either the proportion of oleic acid (from the iodine value) or that of stearic acid (by Hehner and Mitchell's method, *Analyst*, 1896, 321) be determined. —A. S.

Castor oil bean in the Sudan; Experiments in the production of — Board of Trade J., Dec. 2, 1909. [T.R.]

THE Monthly Report of the Sudan Central Economic Board for October states that experiments were carried on at Kassala during the season 1908–9 with the cultivation of the castor oil plant, Java and Indian seed being used. The seed was sown early in September and the harvest took place about the middle of January. The

beans were sold in Hull at about £11 per ton. The cost of cultivation and the yield per acre were as follows:—

	Cost of cultivation per acre.	Yield per acre.
	£	lbs.
Java seed	4.41	1,750
Indian seed	3.67	1,640

The results of an examination, at Khartoum, of samples of the beans produced, were as follows:—

	Java.	Indian.
Percentage of oil	51.48	48.68
Weight of 100 seeds in grms.,	42.6	25.2

The samples were both stated to be of good quality, that grown from Java seed especially so.

China bean oil for candle making in Australia; Denaturation of —. Board of Trade J., Dec. 2, 1909. [T.R.]

THE regulation for the denaturation of China bean oil for free importation into Australia, when for use for the manufacture of candles, is now amended as follows:—To each 100 gallons of oil contained in a vat fitted with a heating appliance, there shall be added not less than four per cent. of sulphuric acid of strength not less than 1.77 sp. gr. at 60 deg. Fahr., and the whole heated to a temperature exceeding 230 deg. Fahr. for at least 30 minutes. Treatment of the oil with dilute sulphuric acid before denaturing may be allowed. (See this J., 1909, 250.)

Beeswax, mineral oils, etc., in Greece; Customs duties on —. Board of Trade J., Dec. 2, 1909. [T.R.]

THE import duties on wax and mineral oils and their derivatives have been modified as shown in the following statement:—

No. of the Tariff.	Tariff Classification.	Rate of Duty.	
		Former.	Fixed by the Law.
8	Yellow beeswax, in cakes or pieces	Drachme (metallic). Per 100 okes. 70-00	Drachme (metallic). Per 100 okes. 170-00
9	Yellow beeswax, in tapers of every kind, or otherwise prepared	125-00	225-00
61h	Residues of distillation of mineral oils, having a blackish or chestnut colour and a melting point not higher than 48°C. and containing not less than 10 per cent. of mineral oils (those of a whitish colour and having a higher melting point and containing a smaller quantity of oils, besides organic substances, being subjected to duty under Tariff No. 99)	(Not specified)	50-00
62	Mineral oils (except petroleum, the importation of which is forbidden as a State monopoly) ...	50-00	100-00
98	(a) Sealing wax	120-00*	120-00
	(c) White wax in cakes		220-00
99	Kerosene, paraffin, stearin, and all artificial waxy substances (without deduction for tare)	120-00	220-00

*White wax in cakes and pieces and sealing wax.

The Law further provides that the use of colophony and resinous substances in general in the manufacture of wax or tapers is prohibited, and that import duty will be returned upon the exportation of paraffin in cakes or tapers manufactured of the residues of mineral oils referred to in No. 61 (h) of the Tariff, and having paid the duty fixed for that number.

Oliver oil; Apparatus for the continuous extraction of —. J. de Acuna y Gomez de la Torre. Fr. Pat. 402,015, May 13, 1909. Under Int. Conv., May 14, 1908.

OLIVES or other oleaginous materials are introduced under pressure, in a continuous process, into an annular space between two concentric cylinders with perforated walls. Meanwhile a current of liquid (e.g. water) is introduced under pressure into the interior space in such a way as to give a rotatory motion to the mass, and carry with it the expressed oil through the perforations in the outer cylinder. The residual material is discharged automatically.

PATENTS.

Paint for use as an anti-fouling composition for ships. E. A. Palk, Totton, Hants., and H. F. Basset and W. Nash, London. Eng. Pat. 21,627, Nov. 16, 1908.

A PAINT prepared by mixing acetone and gold size with a pigment, varnish and turpentine oil, in proportions which are varied according to the colour and thickness of coating required, is found to prevent the adherence of vegetable and animal growths to ships' bottoms.—J. A.

Pigments with a basis of antimony; Manufacture of — and obtaining of by-products. A. Vietti. Fr. Pat. 403,017, Sept. 14, 1908.

ANTIMONY pigments are obtained by injecting solutions of sulphantimonates of metals of the alkali or alkaline-earth groups and also a solution of sodium sulphate into flues conveying sulphurous fumes from the roasting of sulphides, etc. The sulphate is reduced to sulphide, which reacts with the sulphantimonate to

form antimony sulphide and alkali thiosulphate. The latter may either be purified or used in the preparation of antimony vermilion from antimony chloride.—C. A. M.

Ultramarine; Apparatus for the manufacture of —. L. Royer. Fr. Pat. 403,077, May 17, 1909.

CLAIM is made for the use of a furnace, together with its connected pipes and vessels, constructed of carborundum.—C. A. M.

Ultramarine blues; Process and apparatus for the manufacture of —. J. Luciani. Fr. Pat. 403,247, Sept. 19, 1908.

A FURNACE, intended for the oxidation of ultramarine or, in general, for all reactions in which material at a high temperature is treated with gases, is described. It consists essentially of an annular space between two cylinders of brick of special construction. The material is placed in this space, air is admitted through holes in the inner brick cylinder, and the gaseous products of the reaction pass through openings in the bricks in the outer cylinder into a flue above. The furnace is charged from wagons above, and is emptied through openings in the lower part of the annular space.—C. A. M.

Rosin; Method of bleaching —. L. C. Minor, Cincinnati, Ohio. U.S. Pat. 939,733, Nov. 9, 1909.

THE melted rosin is subjected to the action of artificially produced ultra-violet rays in a vessel, the inner sides of which reflect light.—C. A. M.

Artificial resins; Process and apparatus for the manufacture of — from pyroigneous products, with the production of acetates as by-products. Pagès Camus et Cie and P. Bandy. Fr. Pat. 402,907, Sept. 9, 1908.

CLAIM is made for a process of obtaining artificial resins by the interaction of the "phenolic oils," "aldehydic oils" and "aldehydic residues" formed in the distillation of wood or analogous products, preferably in the presence of an acid or alkaline condensing agent. Thus the pyroigneous vapours from the distillation are mixed together at a temperature below 250° C. (acid condensation). The vaporised products are then treated with a substance with alkaline reaction, and the resulting resins dissolved (alkaline condensation). Finally, the solution is neutralised with suitable acids. The three stages may be carried out successively so as to obtain the different kinds of resins formed in the different condensations, and special types of apparatus for the different modifications of the process are described. An alternative process claimed is to render alkaline the mother liquors from the crystallisation of pyroigneous solutions, and to submit them to the general methods of condensation mentioned above, thus obtaining resins, acetates, and a new source for higher fatty acids (butyric acid, etc.). Apparatus for this process is also described. Another alternative is to treat the pyroigneous vapours with an insoluble neutral salt (e.g., calcium carbonate), which is not acted on by phenols but is decomposed by acids. The crude acetates resulting from this process may then be separated and purified.—C. A. M.

Oils; Process for heating (boiling) — for the preparation of varnishes and polymerised oil products. A. Genthe. Ger. Pat. 215,348, June 13, 1908.

TO avoid loss of oil by evaporation during "boiling," and also to prevent oxidation by the air, the vessel in which the boiling is performed is provided with a float, which is of a slightly smaller size than the inner wall of the vessel, so as to leave a small space for the escape of

steam or volatile substances. The vessel is preferably made of aluminium, and it may be protected from damage by flame, by an iron jacket.—T. F. B.

Resins, lacquers, varnishes, and driers; Process for the preparation of transparent coloured —. M. Schwarz. Ger. Pat. 215,549, April 11, 1908.

RESINS or resin-acids when heated to temperatures of from 150° to 420° C., are capable of dissolving dyestuffs of the indanthrene and "algal" classes; and the products may be used for the preparation of coloured lacquers, varnishes, driers, etc.—A. S.

Lacquers containing nitrocellulose; Process for preparing —. B. G. Buchstab. Ger. Pat. 216,307, Jan. 31, 1909.

NITROCELLULOSE is dissolved in a suitable solvent (e.g., is used as collodion) and treated with air, oxygen, ozone, or gases containing oxygen until the solution is a brownish-yellow colour. The thick liquid thus obtained is diluted to suitable consistency with methyl or ethyl alcohol. For preparing paint-oils, etc., the solution is mixed with suitable non-drying or semi-drying oils, and for preparing lacquers, with resins, glycerin, etc. The products may be rendered incombustible by adding lactic acid or a lactate, especially strontium lactate. In place of using nitrocellulose for the process, materials containing nitrocellulose, such as celluloid, may be employed.—T. F. B.

(C.)—INDIA-RUBBER, &c.

Rubber; Influence of protein on the determination of — as tetrabromide. D. Spence. Gummi-Zeit., 1909, 24, 212–213. (See this J., 1909, 1149.)

THE part played by the protein of raw rubber in the Budde method of estimation of rubber as tetrabromide has so far been largely ignored. The author has therefore studied the behaviour of protein, derived from the latex of *Funtumia elastica*, towards bromine under various conditions. The protein was isolated in the following way:—100 c.c. of acid *F. elastica* latex were diluted with 800 c.c. of distilled water in a separating funnel. On standing for 3 hours, the liquid separated into two layers, of which the lower, aqueous serum contained the protein. The serum was drawn off, saturated with ammonium sulphate, and the finely flocculent precipitate obtained filtered off and dissolved in 200 c.c. of distilled water. The solution was filtered, and dialysed against running water for three days. The dialysed solution was saturated with ammonium sulphate, and the purification process repeated, dialysis being finally conducted against distilled water for one day. From this purified solution the solid protein was obtained, (1) by precipitation with three times its own volume of absolute alcohol, washing with 80 per cent. alcohol, and drying *in vacuo*; (2) by evaporation to dryness *in vacuo* over sulphuric acid. Both products gave the following results:—(1) an aqueous solution gave no precipitate on addition of bromine-water. The bromine was completely absorbed, and no protein was precipitated when alcohol was subsequently added; (2) when bromine water was added to a solution of the protein which had been rendered opalescent by the addition of alcohol, the opalescence vanished, and protein could no longer be precipitated from the solution. Protein from *F. elastica* latex therefore yields bromine derivatives which are soluble both in water and in alcohol. 0.156 gm. of dry, finely-divided protein was suspended in 50 c.c. of carbon tetrachloride, the mixture was cooled in ice-water, and 50 c.c. of Budde's bromine solution were slowly added. The liquid was allowed to stand for 24 hours. The small quantity of undissolved protein remaining was filtered off, and the filtrate evaporated to dryness in a current of carbon dioxide. The brown syrupy mass obtained, weighed 0.128 gm. and contained about 16 per cent. of bromine. The undissolved protein was also found to contain bromine, but the amount was not estimated.—E. W. L.

Rubber [*ebonite*]; *Hard vulcanised* — G. Hübener.
Gummi-Zeit., 1909, 24, 213–214.

(1). *A simple method of estimation of sulphur of vulcanisation.*—In the method previously described (this J., 1909, 251) a determination of sulphur in the ash, in addition to determinations of “free” sulphur (including sulphur in sulphides and soluble sulphates) and of total sulphur, was necessary in the presence of insoluble or sparingly soluble sulphates. By proceeding in the following manner instead of employing Henriques’ method for the determination of total sulphur, the first determination becomes unnecessary. To 1 gm. of the finely-rasped ebonite in a 100 c.c. Erlenmeyer flask, 15 c.c. of concentrated nitric acid are carefully added. The flask is then heated first on a sand-bath, and finally on a water-bath in order to drive off the excess of nitric acid. The residue is diluted with water, 3 c.c. of bromine are added, and the flask is again heated until the excess of bromine is removed. The liquid is poured through a filter, and the sulphuric acid in the filtrate precipitated and determined as barium sulphate. The difference between the amount of sulphur thus found, and the “free” sulphur (see above) represents combined sulphur (sulphur of vulcanisation). The author points out that results obtained by the new method are appreciably higher than those obtained by the soda-fusion method (Henriques). This is due to the fact that barium sulphate is appreciably soluble in concentrated solutions of potassium, sodium, calcium and magnesium salts. This solubility is clearly shown by the results of a special series of determinations, in which barium sulphate was fused with sodium carbonate, the melt extracted with water and filtered from barium carbonate, and the sulphate in the filtrate precipitated with barium chloride, whilst the barium carbonate was dissolved in hydrochloric acid, and the barium precipitated with dilute sulphuric acid. The results were as follows:—

	(a) per cent.	(b) per cent.
(1) Sulphate precipitated by barium chloride.....	90.35	93.2
(2) Barium precipitated by sulphuric acid.....	97.55	97.67

The barium sulphate obtained in (2b) was treated in a similar manner, with the following results:

	per cent.
Sulphate precipitated by barium chloride.....	91.69
Barium .. sulphuric acid	99.75

In (1b) and (2b) the proportion of sodium carbonate employed was higher than in (1a) and (2a).

(2). *Investigation of the phenomena of hot vulcanisation.*—Results obtained by the author, in the case of ebonite, by his method of analysis already described (this J., 1909, 251), confirm those obtained by Hinrichsen and Stern, who studied vulcanisation in naphthalene solution (this J., 1909, 1050). The results are as follows, in the case of samples vulcanised under similar conditions:—

No.	Rubber, per cent.	Sulphur, per cent.	Combined sulphur, per cent.
1.....	36.23	22.60	3.62
2.....	29.01	24.39	3.52
3.....	26.58	24.44	3.01
4.....	19.21	22.96	2.88

The author concludes from the results that in mixings containing equal percentages of rubber, the amount of combined sulphur increases with the quantity of sulphur added, and that in mixings containing equal percentages of total sulphur, the amount of combined sulphur increases with the percentage of rubber.—E. W. L.

PATENTS.

Rubber; *Apparatus for cleaning and devulcanising* — M. C. Clark, Providence, R.I., U.S.A. Eng. Pat. 12,250, May 24, 1909.

THE waste rubber is cracked and screened, then treated in an acid bath, washed, devulcanised by means of steam,

disintegrated, and dried. The chief improvements claimed in the apparatus for carrying out the process, are as follows:—(1). The washing tanks are provided with overflow arrangements, each of which includes an inclined screen having a vertical foot-piece at its lower end, whereby any rubber carried by the overflowing liquid is retained. (2). For the operation of devulcanisation, the rubber is packed in a cylindrical car divided into compartments by movable perforated horizontal shelves, and one side wall of which consists of curved sectional plates, to allow of charging the car one compartment at a time; the car is open at the top and has a perforated floor through which steam passes from the devulcanising chamber. (3). The drying apparatus for the disintegrated devulcanised material comprises two superposed endless belts in a casing through which hot air is passed. The material is fed on to the moving upper belt until this is filled; the belt is then stopped for a time, after which the partially dried material is transferred to the lower belt, which moves in an opposite direction to the upper one. The lower belt, when filled, is left at rest until the material is completely dry.—A. S.

Indiarubber (whether vulcanised or not) and similar products; *Process for the recovery or regeneration of* — G. Capelle, Liege, Belgium. Eng. Pat. 27,567, Dec. 18, 1908.

SEE Fr. Pat. 398,583 of 1908; this J., 1909, 895.—T. F. B.

Tannin-extracts; *Process for decolorising* — Deutsche Versuchsanstalt für Lederindustrie und H. Arnoldi, Freiberg, Germany. Eng. Pat. 19,804, Aug. 30, 1909. Under Int. Conv., Sept. 7, 1908.

TANNIN-EXTRACTS are decolorised by treating them with “activated aluminium,” prepared by treating aluminium scrap with caustic alkali solution, rinsing with water, and then treating with mercury chloride and again washing. The tannin-extract is well mixed with the activated aluminium, the mixture heated, agitated, then allowed to cool and settle, and the clear liquid separated and concentrated. The process is said to be specially suitable for the treatment of mangrove-bark, maleto-bark, and quebracho-wood extracts, and the treated extracts produce leather which becomes but little darker under the action of light, and is free from the red shade usually characteristic of leather prepared with these extracts.—A. S.

Horn waste and similar substances; *Process for converting — into plastic materials.* C. Claessen, Ger. Pat. 216,214, Aug. 31, 1906.

THE horn waste or the like is treated with phenols, or aniline, or their derivatives, then mixed with binding agents, such as resins, carbohydrates, glue, casein, etc., and if desired, with glycerin, oil, vulcanised oils, etc., and the mass heated to 120°–150° C. and compressed. A. S.

Sugar cane; Treatment of — and manufacture of useful products therefrom. A. and S. Wynberg, Amsterdam. Eng. Pat. 2219, Jan. 29, 1909.

THE wax and other bodies adhering to the rind of the sugar cane are removed by a system of mechanically operated brushes, which, since the cane is irregular both in size and shape, are so mounted as to be elastic and flexible. The dust removed by the brushes is carried off by an air-blast and collected for further treatment. The juice obtained from cane brushed in this way is found to give better results in filtration and crystallisation than the juice from untreated cane.—J. A.

Beet slices; Continuous extraction apparatus for —. W. Bock. Ger. Pat. 213,021, Aug. 25, 1906.

THE apparatus comprises a series of vertical cylindrical receptacles disposed one above the other. A hollow shaft extends centrally through the receptacles and, near the bottom of each receptacle, is provided for a short distance with a projecting helix, so as to act as a screw conveyor; immediately below each helix the receptacle is contracted, so that the beet slices become compressed and practically impervious to liquid, thus closing communication between adjacent receptacles. In the remaining portion of each receptacle the beet slices remain loose, and come into intimate contact with the extracting liquid. The beet slices are introduced at the top and pass downwards through each receptacle in succession. The extracting liquid passes through the lowest receptacle first, then through the next higher one, and so on, but in each receptacle its direction of flow may be the same as, or opposite to, that of the beet slices. Pipes are provided for conveying the extracting liquid from one receptacle to the next.—A. S.

Yeast-juice; The hexosephosphate formed by — from hexose and phosphate. W. J. Young. Proc. Roy. Soc., 1909, 81B, 528–545.

IT has been shown by Harden and Young that the rate of fermentation of glucose by yeast-juice is temporarily greatly increased by the addition of a soluble phosphate, and that during this period of increased activity, the phosphate undergoes an alteration, so that at the end of the time it is no longer precipitable by magnesium citrate mixture (this J., 1906, 490, 1111; 1907, 62; 1908, 824). They suggested that a combination of the phosphate with the sugar, to form a phosphoric acid ester, had taken place. The present paper embodies work on this substance which has been isolated through the medium of its lead salt. The compound formed during fermentation is the salt of an acid which probably has the formula,

$C_6H_{10}O_4(PO_4H_2)_2$. The free acid, which is obtained in solution by decomposing its lead salt with sulphuretted hydrogen, is very unstable and readily decomposes on keeping, or at ordinary temperature *in vacuo* over sulphuric acid, with formation of a reducing substance and phosphoric acid. The hexose-phosphoric acid reduces Fehlings' solution very slowly in the cold, but rapidly on boiling, whilst no osazone or hydrazone has been obtainable from it. The same hexose-phosphoric acid is obtained from glucose, fructose or mannose, and on hydrolysis by boiling, yields phosphoric acid and fructose; no other hexose could be identified. The salts of lead, barium, silver, and calcium have been prepared.—R. L. S.

Yeast; Distribution of phosphoric acid in — and its alteration during storage. Heinzelmann. Jahrb. Versuchs- u. Lehranst. f. Brau., 1909, 12, 123–124.

EXPERIMENTS with two top-fermentation distillery yeasts, Races XII and M (mixed races) showed that during storage, the amount of inorganic phosphoric acid increases at the expense of the organic phosphoric acid. This increase amounted to 29.4 per cent. of the total phosphoric acid of the yeast in 18 days at 15° C., in the case of Race M, and to 21.8 per cent. in 64 days at 7° C. in that of Race XII. The change is attributed to the action of the yeast peptase (endotryptase), which produces decomposition of the yeast-protein, with formation of phosphoric acid or inorganic compounds of the same from organic phosphorus compounds.—A. S.

Yeast; Action of oxygen on quiescent —. M. Delbrück and F. Hayduck. Jahrb. Versuchs- u. Lehranst. f. Brau., 1909, 12, 34–38.

COMPARATIVE experiments were made as to the effect of treatment with air, on the one hand, and with carbon dioxide, hydrogen or other inert gas, on the other, on the properties, especially the stability, of quiescent yeast. It was found that in general, aeration renders the yeast more resistant to high temperatures, i.e., less liable to liquefy as the result of autodigestion. The favourable action of air is probably due to the repression of the destruction of the protein substance of the yeast by the yeast peptase (endotryptase). It is not yet clear whether the oxygen exerts a direct restraining effect on the peptase, or whether it has a favourable influence on the whole "physiological condition" of the cell (see this J., 1907, 60, 1104; 1908, 1170), such that the synthesising actions overbalance the decomposing actions. From the technical standpoint the results show the importance of aerating quiescent yeast which has to be transported, especially in summer.—A. S.

PATENTS.

Beetroot syrup for the cultivation of yeast; Preparation of —. K. Kruis. Fr. Pat. 402,855, May 10, 1909.

BEETROOT juice, obtained by the processes current in sugar manufacture, is evaporated to a density of 76° Brix. If the beet juice be combined with the juice of potatoes or with a proportion of molasses, the yeast nutrient thus introduced, lowers the coefficient of purity to such an extent that the syrup shows no tendency to crystallise. This syrup, suitably diluted with water, then serves as a medium for the manufacture of pressed yeast. It is stated that yeast thus cultivated in sucrose media is superior to that obtained from maltose worts.—J. F. B.

Alcohols and other volatile liquids; Distilling —. A. G. Waterhouse, Good Ground, N.Y. U.S. Pat. 939,361, Nov. 9, 1909.

THE principle of the process consists in heating the liquid to a degree sufficient to cause the vaporisation of substantially all the alcohol contained in it, maintaining the temperature approximately at this point, and controlling the introduction of fresh liquid by the temperature of that under distillation. The cold fresh liquid is caused to absorb the heat from the outgoing hot spent liquid to such a point that the alcohol in the first is partly vaporised and the vapours so produced control the inflow of alcoholic liquid and the discharge of exhausted liquid.—J. F. B.

Recovery of tartrates. Fr. Pat. 402,999. See XX.

(B.)—SANITATION; WATER PURIFICATION.

Nitrates; Decomposition of — by micro-organisms. H. Franzen and E. Löhmann. Z. physiol. Chem., 1909, 63, 52—102.

THE authors have investigated the action of various bacteria on nitrates, and have determined the extent to which the nitrate is attacked in cases where such action has taken place. The experiments were made on potassium nitrate dissolved in peptone broth and to which cultures of the organisms were added. At the end of the experiments both the nitrate and nitrite present in the solutions were determined by the method described by Busch (this J., 1906, 499). From the results obtained the bacteria may be classified as follows:—(1). Those which decompose nitrate with the production of nitrite: these include *B. Plymouthensis*, *B. prodigiosus*, *B. Kiliensis*, *Proteus vulgaris*, *B. coli communis*, and *B. typhi murium*. (2). Those which attack the nitrate but without the formation of nitrite; *B. pyocyaneus* belongs to this class. (3). Such bacteria as *B. fluorescens liquefaciens* which does not reduce nitrates. The bacteria which reduced the nitrate did so to the extent of from about 60 to 100 per cent. of the quantity of nitrate present: *B. typhi murium* appeared to be the most active, reducing the whole of the nitrate in 2 days. In the case of *B. pyocyaneus*, the reduction did not result in the evolution of nitrogen. Other observers have stated that *B. fluorescens liquefaciens* readily reduces nitrates, but the authors are unable to confirm this; they used two different cultures of the organism in their experiments and in neither case could any action on the nitrate be observed. It has also been stated that *B. Kiliense* forms only small quantities of nitrite, but it was found that this organism produced in the same length of time larger amounts of nitrite than did *B. Plymouthensis*, *B. prodigiosus*, and *Proteus vulgaris*.—W. P. S.

PATENTS.

Waters; Process for the purification of calcareous —. J. P. Lajoie. Fr. Pat. 403,172, Sept. 17, 1908.

A PORTION of the water flowing along a main, such, for instance, as the supply pipe of a boiler, is caused to pass through a side tube and vessel containing crystals of potassium acid oxalate. A small quantity of the latter is dissolved and the water is then conducted back to the main. By regulating the flow of water through the side tube, the quantity of oxalate necessary to precipitate the calcium salts in the water is dissolved.—W. P. S.

Testing air or gas by means of colour changes of one or several reagents carried on threads or the like. M. Arndt. Ger. Pat. 211,893, Jan. 10, 1908.

TWO or more threads, or strands, or ribbons, each serving as a vehicle for a reagent, are brought together (by crossing, by winding together, etc.) in such a manner that the reagents come into intimate contact. For example, the proportion of carbon dioxide in the air of a room can, it is stated, be determined approximately by making a thread moistened with lime water cross uniformly and continuously a thread impregnated with an alcoholic solution of phenolphthalein, and observing the depth of the coloration produced.—A. S.

Water; Process for purifying —. C. W. Schultze. Buffalo, U.S.A. Eng. Pat. 5676, March 9, 1909.

XIX.—PAPER, PASTEBOARD, &c.

PATENTS.

Sizing and coating machines chiefly for use in sizing and coating paper. S. Milne, Edinburgh. Eng. Pat. 16,327, Aug. 1, 1908.

A SINGLE large cylinder or a series of smaller cylinders is arranged to receive the paper as it leaves the coating cylinder and rollers. The paper is guided and supported, before passing on to the cylinder, by a series of devices arranged in a curved path, and by means of a series of rolls and curved bars it is extended to its greatest width. By this stretching during the subsequent drying a greater width of paper may be treated without risk of damage than was previously practicable. Around the outside of the large cylinder and covering about one-half of it, there is a concentric envelope or hood confining a current of hot air moving in an opposite direction to the paper. The cylinder itself is heated by steam if necessary, and any further heating is supplied by a supplementary series of rollers which receive the paper after it passes off the cylinder. But the distance between the coating brushes and the cylinder, and the size of the cylinder itself, are arranged so that the paper comes off the cylinder dry. This drying machine is particularly suitable for the treatment of paper sized with starch.—S. B. H.

Paper pulp; Preparation of —. M. Nerson, sen. Fr. Pat. 403,023, Sept. 14, 1908.

THE process, especially applicable to the treatment of straw with milk of lime, consists in digesting the material in the ordinary form of rotary boiler, at a suitable temperature, under a pressure obtained by means of compressed air. In this way the pressure is obtained independently of the temperature, and the latter may be reduced to such a point that the fibre is not injured by the process. Besides maintaining the pressure necessary for the proper penetration of the material, the compressed air also effects an energetic agitation of the mass.—J. F. B.

Paper pulp from all kinds of plants; Manufacture of —. A. W. Audibert. Fr. Pat. 403,151, May 19, 1909.

ACCORDING to this specification, all kinds of plants, particularly the parasitic plants of the forests of the Landes, are converted into paper pulp by digestion with a filtered extract of ashes of any kind, but preferably

those resulting from the combustion of resinous materials. The ash solution is first boiled with rosin and the liquid thus obtained is used for the digestion of the vegetable materials by boiling in a closed vessel for 12–15 hours.

—J. F. B.

Sulphite-cellulose liquors; Process for the purification of —. A. Kumpfmüller. Ger. Pat. 216,284. Sept. 14, 1907.

THE waste liquors from the manufacture of sulphite-cellulose are freed from sulphurous acid and calcium sulphite by evaporation in a vacuum apparatus, and are then treated with a solution of alum. The precipitate produced is separated. The solution thus obtained is suitable for use as a filling material in tanning and leather-dyeing.—A. S.

New solvent for nitrocellulose. Fr. Pat. 402,950. See V.

Lacquers containing nitrocellulose. Ger. Pat. 216,307. See XIII B.

Cattle food from sulphite-cellulose waste liquors. Fr. Pat. 402,871. See XVIII A.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENTIAL OILS, & EXTRACTS.

Harmaline, a substitute for quinine. J. A. Gunn. Roy. Soc. Edin., Nov. 22, 1909. Chem. and Drug., 1909, 75, 808.

HARMALINE is the more important of two alkaloids found in the seeds of *Peganum harmala*, a plant which grows wild over a large area of Southern Europe, Egypt, and Asia. The seeds were used medicinally by the ancient Greeks, as they are to this day in India. The author finds that harmaline belongs to the group of protoplasmic poisons of which the best known alkaloid is quinine, and the actions of harmaline and quinine are practically the same, so that it is possible that harmaline may come to be used as a substitute for quinine.

p-Hydroxyphenylethylamine; Isolation and synthesis of —, an active principle of ergot, soluble in water. G. Barger. Chem. Soc. Trans., 1909, 95, 1123–1128.

IN addition to ergotoxine (see this J., 1907, 483), the author and Dale (Biochem. Zeits., 1907, 2, 286) have suggested that ergot contains another active principle which is soluble in water. *p*-Hydroxyphenylethylamine has now been detected in the aqueous extract of ergot, and the presence of this base satisfactorily accounts for such of the physiological activity of pharmaceutical preparations of ergot as is not due to the small quantities of ergotoxine present. The base was isolated by adding sodium carbonate to the concentrated aqueous extract of ergot, and then extracting with amyl alcohol. The crude base was separated from the large quantities of inactive substances accompanying it, by a complicated method of purification, including treatment with mercuric chloride in alcoholic solution, and was finally isolated by utilising its slight solubility in ether. It was purified by means of its dibenzoyl-derivative.

As only very small quantities of the base could be isolated, it was prepared synthetically by the reduction of *p*-hydroxyphenylacetonitrile with sodium in alcoholic solution. The base is best purified by distillation (b. pt. 161°–163° C. at 2 mm.; 175°–181° C. at 8 mm.). When crystallised from alcohol it forms hexagonal leaflets melting at 161° C. It is soluble in about 10 parts of boiling alcohol, somewhat less soluble in boiling water, much less in boiling xylene, and hardly soluble at all in cold xylene. Xylene is the most suitable solvent for purifying the base by recrystallisation. By the methylation of *p*-hydroxyphenylethylamine with methyl iodide, a quarternary iodide is obtained, which is identical with the methiodide of hordenine, the alkaloid present in malt culms (see Léger, this J., 1906, 133).—A. S.

p-Hydroxyphenylethylamine; Further syntheses of —. G. Barger and G. S. Walpole. Chem. Soc. Trans., 1909, 95, 1720–1724.

p-HYDROXYPHENYLETHYLAMINE, a physiologically active principle of ergot, has been prepared previously by the reduction of *p*-hydroxyphenylacetonitrile (see preceding abstract). Two new methods of preparation have now been devised. (1) Benzoyl-*p*-nitrophenylethylamine, prepared by nitrating benzoylphenylethylamine with fuming nitric acid below 5° C., was reduced with tin and hydrochloric acid, and the amino-compound was converted into benzoyl-*p*-hydroxyphenylethylamine by treating its boiling solution in dilute sulphuric acid with sodium nitrite. This compound, when hydrolysed by heating with 20 per cent. hydrochloric acid at 140° C., yielded *p*-hydroxyphenylethylamine. (2) Anisaldehyde was condensed with ethyl acetate by means of finely-divided sodium (compare Perkin and Robinson, this J., 1907, 864), and the resulting *p*-methoxyphenylpropionic acid was converted first into the chloride and then into the amide. The latter, when heated with bromine and sodium hydroxide (Hofmann's reaction) yielded *p*-methoxyphenylethylamine, from which the methyl group was removed by heating with hydrobromic acid.—A. S.

Physostigmine; Fluorescent substance derived from —. P. Gaubert. Comptes rend., 1909, 149, 852–853.

AN aqueous solution of physostigmine is allowed to stand for some months till its colour has become dark blue. On adding hydrated phthalic acid, the liquid at once exhibits a strong blood-red fluorescence, much stronger than that shown by any known fluorescent substance. The crystals of this new substance are dark blue, and silk, cotton, alcohol, ether, crystals of meconic acid, etc., coloured by it are also blue, but show no fluorescence. The aqueous solution of the crystals, however, even when diluted so as to be almost colourless by transmitted light, shows by reflected light a colour comparable with that of the finest rubies.—J. T. D.

Coumarin; Influence of anæsthetics and of frost on plants containing —. E. Heckel. Comptes rend., 1909, 149, 829–831.

GUIGNARD and Mirande have recently shown (Comptes rend., 1909, 149, 91 and 140) that cold and anæsthetics (ether and chloroform) determine the decomposition of glucosides in plants which contain them, and that this effect is produced by plasmolysis, with an extrusion of water from the cytoplasm and an exosmosis of this water charged with various substances which react on one another outside of the cells. The author has examined the effect of the same agencies on plants yielding coumarin, but which give no odour of coumarin until they are dried—*Anthoranthum odoratum*, *Liatris odoratissima*, *Angraecum fragrans*, in which the coumarin is free, and *Melilotus officinalis*, in which it is combined. In all cases, at once or after a very short time of exposure, a dew or hoar frost forms on the surface of the leaves (with or without blackening, according to the plant and the odour of coumarin is strongly apparent; and in all cases the phenomena are accompanied by plasmolysis. Similar experiments with certain crucifers showed an equally rapid formation of mustard oil.—J. T. D.

Ajuga reptans. U. Ponti. Gaz. chim. ital., 1909, 39, II., 349–353.

Ajuga reptans or "fever-herb," a plant of the order Labiate, grows abundantly in Sardinia, and is stated to be a remedy for malarial fever. By steam distillation of the dry herb, a very small quantity of a greenish oil was obtained, which had a characteristic, aromatic, pungent odour. No indication of the existence of alkaloids in the herb could be obtained by the usual tests. By boiling the finely divided herb with milk of lime and filtering, an orange-red solution was obtained, from which after acidifying with hydrochloric acid, diluting, and saturating with ammonium chloride, there was separated by extraction with ether, a substance which, after purification, formed fine long colourless needles, melting at

170° C.; the yield of the crude substance was about 1 part per 1000 of dry herb. This substance, on examination, proved to be identical with ferulic acid, $C_6H_5(OH)(OCH_3).CH:CH.CO_2H$ (see Bamberger, this J., 1892, 365; Power and Tutin, this J., 1907, 635). Ferulic acid is easily soluble in alcohol and ethyl acetate, and soluble with difficulty in benzene and petroleum spirit.
—A. S.

Lemon oil; Occurrence of pinene in —. E. M. Chace. U.S. Dept. Agric., Bureau of Chem., Circular No. 46, Oct. 30, 1909.

DURING May, 1907, certain lots of lemon oil imported from Sicily were found at New York to possess abnormal physical constants and to contain substantial amounts of pinene. The Board of Food and Drug Inspection regarded them as adulterated in consequence. In order to settle the dispute which arose over the oils in question, the author was sent to Sicily to collect authentic samples of the oil and examine their physical constants and to determine whether pinene was normally present or not in such oils. Samples of the oil were taken from the bowls of the workmen in factories situated in different parts of Sicily, and compared with samples drawn from the manufacturers' stock and with samples of the oils regarded as adulterated in 1907 owing to the presence of pinene. Comparison was also made with oils imported in 1907, which were found to be free from pinene. The oils were examined for sp. gr. at 15.5° C., optical rotation at 20° C., and refractive index at the same temperature. 50 c.c. of the oil were then distilled as described in Schimmel and Co.'s Report for 1898, p. 41, and the optical rotation of the distillate determined at 20° C. The distillate was mixed with an equal volume of glacial acetic acid and placed in a freezing mixture. 10 c.c. of ethyl nitrite were then added, followed by 2 c.c. of a mixture of hydrochloric acid and water (2:1). The crystals were filtered off after 15 minutes, dissolved in chloroform and re-precipitated with methyl alcohol. The crystals were mounted in olive oil and examined under a microscope with a magnification of 100. Pinene nitrosochloride is easily detected, as the crystals are broad with irregular pyramidal ends, whilst limonene nitrosochloride crystallises in needles (this J., 1908, 1174). The citral was determined by the fuchsine sulphite colorimetric method. No trace of pinene was found in 15 samples of lemon oil made under the author's supervision; nor in 130 samples collected from the workmen's bowls. The physical constants of these oils were, on the whole, normal. 33 samples obtained from dealers in Sicily were, with one exception, free from pinene. This one specimen showed the presence of pinene, but was normal in all other respects. The author concludes that the presence of pinene in lemon oil, if shown by the above test, is proof of adulteration, even if the physical constants are normal or otherwise.—F. SIDDON.

Lemon oil; The pinene question. E. J. Parry. Chem. and Drugg., 1909, 75, 875—876.

THE author criticises the report published by the U.S. Dept. Agric. on the presence of pinene in lemon oil (see preceding abstract). In 1907 the Department refused admission to the United States of about 100,000 lb. of lemon oil, which was subsequently accepted. Outside the U.S.A. the general opinion seems to have been that the oil in question was pure. Schimmel and Co. in their "Report" for 1897 regarded lemon oil containing pinene as adulterated. Burgess and Child in 1902 stated that pinene was a normal constituent of pure lemon oil. In October, 1908, Schimmel and Co. published in their "Report" the results of an examination of 36 authentic samples of Sicilian lemon oil, and pinene was found to be present in each. The sp. gr. and optical rotation of lemon oil vary with the circumstances of the pressing of the oil. After examining Chace's figures for the optical rotation of the oils alleged to be adulterated, and of the authentic samples, the author considers that there cannot have been more than 3 per cent. of turpentine present. Wallach has shown (Annalen, 252, 106; 270, 174) that

limonene yields an α - and a β -nitrosochloride, which differ in their crystalline form. The author does not consider the microscopic test for pinene to be sufficient evidence of adulteration.—F. SIDDON.

Iodine and acetone; Dynamics of the reaction between —. H. M. Dawson and M. S. Leslie. Chem. Soc. Trans., 1909, 95, 1860—1870.

ACETONE solutions of iodine, alone or in presence of iodide, become strongly acid on keeping, and the iodine concentration is considerably reduced. The reaction is reversible, since, for a solution of a given concentration, a definite end-point appears to be attained. In presence of moderate concentrations of hydrogen ions the reaction proceeds with measurable velocity at the ordinary temperature, but in absence of added acid, the reaction is very slow at first, the velocity increasing as hydriodic acid is gradually produced. In solutions of acetone in carbon tetrachloride, methyl alcohol, methyl acetate, benzene, and nitrobenzene, and in the case of anhydrous acetone, the action of the iodine is much less complete than in aqueous solution, but proceeds much more rapidly. When 50 c.c. of each of the solvents mentioned were mixed with 5 c.c. of acetone and 0.5 gm. of iodine, the amount of unchanged iodine left when the reaction was complete, was as follows for the different solvents: carbon tetrachloride, 72; benzene, 72; methyl acetate, 62; nitrobenzene, 57; and methyl alcohol, 47 per cent. Under similar conditions the proportion of unchanged iodine in an aqueous acetone solution was only 0.35 per cent. In the case of aqueous solutions the results can be best explained by accepting Lapworth's view (Chem. Soc. Trans., 1904, 85, 30) that the reaction between halogens and acetone takes place in two stages, viz., the transformation of the ketonic form of acetone into the enolic form, which is accelerated by acids; and the interaction of iodine and enolic acetone, the velocity with which this takes place being relatively so great that this second stage is practically without influence on the rate at which the iodine disappears.—A. S.

Determining hypophosphoric, phosphorous, and hypophosphorous acids in presence of each other and of phosphoric acid. Rosenheim and Pinsker. See VII.

PATENTS.

Compounds [of eugenol-albumin and iso-eugenol-albumin] for internal use. H. Belart, Huddersfield, and Digit Disinfectant Co., Ltd., London. Eng. Pat. 26,075, Dec. 3, 1908. Addition to Eng. Pat. 9246 of 1908, dated June 15, 1907.

THE eugenol-albumin and isoeugenol-albumin compounds mentioned in the chief patent (this J., 1908, 998) when treated with salts of iron, mercury, arsenic and the like, form metallic compounds suitable for use in medicine.

—J. A.

Fluorine-albumin compound; Process for preparation of a —. F. A. V. Klopfer. Ger. Pat. 216,216, March 7, 1908.

THE protein of wheat, freed from nuclein and purine compounds, is treated with aqueous hydrofluoric acid at the ordinary temperature. The product, which is insoluble in water, is stated to be of therapeutic value, especially in the treatment of diabetes.—A. S.

Benzoates; Process of making —. E. O. Barstow, Assignor to The Dow Chemical Co., Midland, Mich. U.S. Pats. 939,584, 939,940, and 939,941, Nov. 9, 1909.

(1) HOMOLOGUES of benzene are oxidised to benzoic acid by treatment with bleaching powder in presence of water and sufficient lime to neutralise the acid formed by the reaction. (2) Sodium hypochlorite and sodium hydroxide may also be utilised for the purpose, as may other alkali hypochlorites and hydroxides. (3) "Partially oxidised oxygen-containing products of members of the benzene series" are oxidised to benzoates by means of bleaching powder and lime as in (1).—T. F. B.

Tartrates; Process for the recovery of — from materials containing the same. J. A. Jude. Fr. Pat. 402,999, May 13, 1909.

THE object of the invention is the recovery of the whole of the tartaric acid present in musts, wines, mares, lees, tatars, vinasses, etc. in the form of potassium bitartrate. The process consists in first acting on the material with hydrochloric acid, sulphuric acid, chlorides, sulphates, or other suitable reagent, or any mixture of these, employed simultaneously or successively, with the object of bringing about solution, and, after the separation of insoluble matter and any precipitate produced, adding a potassium salt (such as the chloride) and a carbonate (such as that of sodium), simultaneously or in succession, so as to obtain a precipitate very rich in potassium bitartrate. The process does not in any way interfere with the recovery of alcohol which is preferably removed afterwards. Claim is also made for the use of a potassium salt and any carbonate, in the place of potassium carbonate, in manufacturing processes generally.—F. SOUX.

Organic dithio-acids (carbothioacids); Process for preparing —. I. Bloch and F. Höhn. Ger. Pat. 214,888, Oct. 27, 1908.

ORGANIC dithio-acids, $R.CSSH$, such as dithiosalicylic acid, are obtained by the action of hydrogen persulphide on aldehydes in presence of condensing agents, and treating the products with alkalis. This process is a general one, whereas the sole method hitherto known (action of carbon bisulphide on organo-magnesium compounds) had only a limited application.—T. F. B.

p-Nitrobenzyl alcohol; Process for preparing —. O. Dieffenbach. Ger. Pat. 214,949, March 28, 1907.

p-NITROTOLUENE is oxidised to *p*-nitrobenzyl alcohol by treatment with lead peroxide and concentrated sulphuric acid; artificial cooling must be resorted to, if necessary, to prevent the oxidation proceeding too far.—T. F. B.

Compounds containing sulphur (thiozonides); Process for preparing —. P. Koch. Ger. Pat. 214,950, March 19, 1908.

ALCOHOLS or esters of the terpene series, or essential oils containing considerable proportions of these substances, such as pine-needle oil or oil of lavender, are converted into sulphur derivatives (thiozonides) by heating with sulphur, either alone, or in closed vessels in presence of alcohol. The compounds formed contain three atoms of sulphur to each double-linkage of the terpene molecule, except with linalool esters, in which case the double-linkage adjacent to the alcohol group is inactive. The products are soluble in ethyl acetate and in essential oils, and also in alcoholic solutions of sodium thiozionate, Na_2S_4 . They are suitable for use in pharmacy.—T. F. B.

Arsinosalicylic acid ($OH:COOH:AsO_3H_2=1:2:4$); Process for preparing —. W. Adler. Ger. Pat. 215,251, Nov. 6, 1907.

o-TOLUIDINE is fused with arsenious acid, the product is acetylated, and the methyl group of the resulting 1-amino-2-methylbenzoic-4-arsinic acid is oxidised to a carboxylic acid group by means of alkaline permanganate solution. Arsinoanthranilic acid, obtained by saponifying the resulting substance, is diazotised and the diazo solution boiled, when arsinosalicylic acid crystallises out on cooling. It is less toxic than sodium *p*-aminophenylarsinate, and can be utilised in place of the latter in pharmacy.—T. F. B.

Mercuric iodide-iodofatty acid compounds; Process for preparing —. J. D. Riedel A.-G. Ger. Pat. 215,664, May 1, 1908.

COMPOUNDS of mercuric iodide with iodo-derivatives of higher fatty acids (see Ger. Pat. 202,790; this J., 1908, 1223) are obtained by the action of mercuric oxide and hypo-iodous acid on elaeomargaric acid, or on saponified

wood oils containing this acid, or on the fatty acids from wood oils. The products are dark and unctuous, insoluble in water, and soluble in alcohol, benzene, and acetone; they are stated to be of therapeutic value.—T. F. B.

Chlorobenzyl alcohols; Process for separating o- and p- —. Farbwerke vorm. Meister, Lucius, und Brüning. Ger. Pat. 215,704, May 21, 1908. Addition to Ger. Pat. 207,157, June 26, 1907. (See Fr. Pat. 389,750 of 1908; this J., 1908, 1041).

o-CHLOROBENZYL alcohol has a boiling point of $230^\circ C$, and the *p*-compound about 5° higher; the separation of mixtures of the two isomerides can therefore be effected by careful fractionation, preferably *in vacuo*, and subsequent crystallisations. It is preferable to cool the melted mixture of alcohols to about $40^\circ C$. (the melting point of a mixture of equal parts of the two isomerides), and then to fractionate the portion remaining liquid.—T. F. B.

Thiosinamine solutions; Process for preparing concentrated —. E. Merck. Ger. Pat. 215,789, Feb. 27, 1909. Addition to Ger. Pat. 163,804, Dec. 13, 1904.

CONCENTRATED solutions of thiosinamine may be rendered stable by adding substances which have both basic and acidic properties, e.g., alkali biphosphates, alkali benzoates, alkali cinnamates, glycecol, or urethane.—T. F. B.

Aldehyde-bisulphites; Process for preparing nitrogen derivatives of —. Chem. Fabr. von Heyden. Ger. Pats. 216,072 and 216,073, Sept. 15 and Oct. 1, 1908.

THE salts of iminodimethylsulphurous acid, $NH(CH_2.O.SO_2H)_2$, are obtained by the action of one mol. of ammonia on two mols. of formaldehyde-bisulphite, or by the action of one mol. of ammonia on less than two mols. of formaldehyde-bisulphite and distilling the resulting product to decompose the aminomethylsulphite which is also formed. Primary amines may be used in place of ammonia, and other aldehyde-bisulphites may be employed. When one mol. of ammonia is heated with three mols. of an aldehyde and three mols. of a bisulphite, salts of nitrosoaldehyde-sulphurous acids, e.g., $N(CH_2.O.SO_2H)_3$, are produced. The above processes are suitable for use with aldehydes, the bisulphite compounds of which are not easily decomposed by ammonia in the cold (e.g., formaldehyde and acetaldehyde).—T. F. B.

Formaldehyde-sulphoxylic acid; Process for preparing nitrogen derivatives of —. Chem. Fabr. von Heyden. Ger. Pats. 216,074 and 216,121, Sept. 15 and Oct. 7, 1908.

WHEN the salts of iminodimethylsulphurous acid, obtained as described in Ger. Pat. 216,072 (preceding), are reduced by means of finely-divided metals, with or without acids, corresponding nitrogen derivatives of formaldehyde-sulphoxylic acid are obtained. The calcium salt reduces acidified indigo-carmin solution in the cold. The salts of nitrilomethylene-sulphurous acid (Ger. Pat. 216,073, preceding) can also be similarly reduced to nitrilomethylene-sulphoxylates, e.g., $N(CH_2.O.SONa)_3$; these salts also reduce indigo-carmin solutions in the cold. Mixed reducing agents can be obtained by reducing mixtures of iminodimethylsulphites and nitrilomethylene-sulphoxylates.—T. F. B.

Antimony-calcium lactate from calcium lactate; Process for preparing —. Chem. Werke Schuster und Wilhelmy A.-G. Ger. Pat. 216,158, June 2, 1906.

ANTIMONIOUS fluoride solutions are treated in the cold with $2\frac{1}{2}$ mols. of calcium lactate dissolved to a neutral solution in water saturated with calcium sulphate; the solutions are then filtered and evaporated to obtain the double lactate. The product is readily soluble in water without addition of lactic acid, and has the formula, $Sb(C_3H_5O_3)_3.Ca(C_3H_5O_3)_7$.—T. F. B.

Dibromophenylglycine-o-carboxylic acid: Process for preparing —. Act.-Ges. I. Anilinfabr. Ger. Pat. 216,266, March 20, 1908.

By brominating phenylglycine-o-carboxylic acid in mineral acid solution (e.g., in 50 per cent. sulphuric acid), a dibromo-derivative is obtained, which contains both the bromine atoms in the benzene nucleus.—T. F. B.

Alkali salts of mercury compounds of hydroxybenzoic-sulphonic acids and their homologues: Process for preparing — soluble in water. Chem. Fabr. von Heyden A.-G. Ger. Pat. 216,267, April 26, 1908.

MERCURY derivatives of the sulphonic acids of hydroxybenzoic acids or their homologues, prepared, for example, by heating the acid with water and mercuric oxide, are sparingly soluble or insoluble in water. They can be converted into soluble compounds by treatment with alkalis; no precipitation of mercury takes place. The new products are of therapeutic value, and are especially adapted for intramuscular injection.—T. F. B.

Tuberculosis: Process for the preparation of a preventive of, and remedy for —. Rosenbach. Ger. Pat. 216,310, March 18, 1908.

Trichophyton fungi, especially *T. holocricum album*, are cultivated on an active culture of living virulent tubercle bacilli on a suitable medium, and after 8–12 days, the fungus culture is separated in the usual manner, ground, and extracted with glycerin-phenol solution. The solution is freed from bacteria by filtration and concentrated *in vacuo*.—A. S.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

PATENTS.

Colour photography: Manufacture of a screen for —. C. Späth, Steglitz, Germany. Eng. Pat. 3601, Feb. 13, 1909.

A LAYER of gelatin is sensitised with bichromate and exposed to light under a black and white screen; it is then dyed in a solution containing two dyestuffs, one of which dyes only unaltered gelatin and the other only altered gelatin; for example, a solution of Ponceau BO and Brilliant Azurine may be used, in which case the gelatin which has been affected by light only absorbs the former, whilst the unaltered gelatin only absorbs the blue. The gelatin sheet is now washed and again sensitised and exposed under the screen, which is this time placed at an angle of about 45° to its former position; the gelatin is washed for a short time and immersed in a solution of a yellow dyestuff (e.g., Flavazine) which will only dye the parts of the gelatin unaffected by light. There is thus obtained a screen coloured red, blue, and green. The process may be modified by washing out a portion of one of the first dyestuffs after the second exposure, and then dyeing the colourless areas.—T. F. B.

Cinematograph films and waste portions of the same: Process for recovering the material of the support of — and the metallic silver of the pictures. H. Danzer, Paris. Eng. Pat. 14,407, June 19, 1909.

OLD or broken cinematographic films are treated with preparations containing soluble or living ferments, to

dissolve away the gelatin; the silver compound is then washed off the residue, which is again worked up. Such ferments as pepsin, trypsin, or papain may be used, and also various liquefying bacteria.—T. F. B.

Photographic plates for use with Röntgen rays. H. Baer. Ger. Pat. 215,649, June 18, 1907.

PHOTOGRAPHIC plates are rendered much more sensitive to Röntgen rays if the emulsion is incorporated with lead glass, or some other material which readily absorbs the rays; lead glass may also be used as support for the emulsion with the same result.—T. F. B.

XXII.—EXPLOSIVES, MATCHES, &c.

Perchloric acid esters. K. A. Hofmann, A. Zedtwitz, and H. Wagner. Ber., 1909, 42, 4390–4394.

THE mono-perchloric ester of monochlorhydrin, $\text{ClO}_4\text{CH}_2\text{CH}(\text{OH})\text{CH}_2\text{Cl}$, was prepared by dissolving 10 c.c. of epichlorhydrin in 40 c.c. of ether, and adding gradually, at 0°–5° C., 16 grms. of perchloric acid of sp. gr. 1.72 (containing 62–63.2 per cent. of perchloric acid). After 1–2 hours the reaction-product was shaken with 50 c.c. of water, and the ethereal solution separated, dried with anhydrous sodium carbonate, and evaporated *in vacuo*. The ester was thus obtained as a heavy colourless oil; yield, 11 grms. It explodes violently on heating, and more readily than nitroglycerin on percussion; with gun-cotton it yields gelatins which burn more vigorously than those prepared with nitroglycerin. It is, however, useless for technical purposes owing to the ease with which it is decomposed in contact with water. The mono-perchloric ester of glycol, $\text{ClO}_4\text{C}_2\text{H}_4\text{O.C}_2\text{H}_4(\text{OH})$, prepared in a similar manner from ethereal solutions of ethylene oxide and perchloric acid, has similar properties to the chlorhydrin ester, but is somewhat more resistant to water.—A. S.

Cartridge manufacture. Statutory Rules and Orders, 1909, No. 1337. [T.R.]

An order dated Nov. 15, 1907, applies the provisions of Sect. 116 of the Factory and Workshop Act, 1901, with modifications, to factories in which the manufacture of cartridges (and also of tobacco, chocolates, and sweet-meats) is carried on. It relates to the furnishing of workers with particulars as to rates of wages and work to be done, and also to the penalties which may be imposed in case of the disclosure of a trade secret.

PATENTS.

Explosives. E. H. Harris, London. Eng. Pat. 28,012, Dec. 23, 1908.

THE explosive is prepared by mixing together pulverised potassium perchlorate and carbon, which are then incorporated with a hydrocarbon, such as naphthalene or benzene, or both, and with nitro-derivatives of naphthalene and benzene in granular form. Five per cent. of paraffin oil and not more than 1 per cent. of castor oil are also added, to act as a lubricant and to facilitate the making of cartridges, the method of doing this being also claimed. The following mixtures are given as illustrations:—

	Potassium perchlorate.	Carbon.	Naphthalene.	Nitronaphthalene.	Nitrobenzene.
(1.) Deep mines, bad ventilation, hard	84.5	4.3	4.0	7.2	0.0
(2.) " " " soft	83.4	1.3	4.0	3.6	3.0
(3.) Shallow mines, medium	83.4	5.0	4.0	5.4	2.2
(4.) Surface, hard	82.3	4.0	6.0	7.2	0.0
(5.) Surface, soft	78.0	10.0	5.0	3.6	4.4

The mixture in each case should contain sufficient oxygen to oxidise the carbon to carbon monoxide or dioxide as well as to form steam with the hydrogen present.

—C. J. G.

Explosives; Plastic ammoniacal saltpetre — Vereinigte Köln-Rottweiler Pulverfabr. A.-G., Berlin, Germany. Eng. Pat. 3937, Feb. 17, 1909.

AMMONIUM nitrate explosives hitherto obtainable commercially suffered from the necessity of using larger bore-holes for them as compared with nitroglycerin explosives. To increase their density, a solution of "nitro-semi-cellulose" (see Eng. Pat. 5126 of 1904; this J., 1904, 560) in nitrobenzene, nitrotoluene, or nitroxylenes is prepared, and 6 to 15 per cent. of this is mixed with 78–85 per cent. of ammonium nitrate, with or without the addition of potassium nitrate. This mixture may be used in place of ammonium nitrate in the preparation of explosives of known kinds. Aniline metallic salt compounds may also be added. —C. J. G.

Explosives; Mixing machine for — H. Talley, Joplin, Mo. U.S. Pat. 940,216, Nov. 16, 1909.

THE machine is of the ordinary type, for the manufacture of high explosives, with the exception that the mixing pan, in which the stirrer-blades work, can be held in position, or can be either lowered or raised, by hydraulic pressure. —G. W. McD.

Explosive. C. U. Buck, Wellshoro, Pa., Assignor to Buck Explosive Co., Coudersport, Pa. U.S. Pat. 940,580, Nov. 16, 1909.

TRINITROPHENOL and dinitrophenol are melted together, soluble gun-cotton is then added, and the mass is heated to 350° F., and incorporated with a mixture of melted paraffin and barium nitrate and with carbon.

—G. W. McD.

New solvent for nitrocellulose. Fr. Pat. 402,950. See V.

XXIII.—ANALYTICAL CHEMISTRY.

APPARATUS.

Melting points; Apparatus for the determination of — and of the solubility of small quantities of substances. H. Stoltzenberg. Ber., 1909, 42, 4322–4324.

FIG. 1.

FIG. 2.

THE apparatus, which is, in principle, a small "Mammoth-pump," is shown in the accompanying diagram (see Fig. 1). The thermometer and melting-point tube are placed in the wide observation tube, which contains the heating liquid, and the latter is kept in circulation by means of bubbles of an inert gas (e.g., carbon dioxide), passed in at the bottom of the heating coil through the narrow tube. The bulb at the top of the heating coil is provided with a bubble-pricker. High temperatures can be quickly reached, and then on removing the burner from below the heating coil, the heating liquid can be rapidly cooled again. For solubility determinations, the substance is placed on a piece of wire gauze or a glass-wool plug in the observation tube. For determining solubilities at low temperatures, the apparatus shown in Fig. 2 is used, the spiral being placed in a refrigerating mixture. —A. S.

PATENT.

Testing fluids; Apparatus for — H. B. Bishop, Assignor to General Chemical Co., New York. U.S. Pat. 940,850, Nov. 23, 1909.

SEE Fr. Pat. 394,107 of 1908; this J., 1909, 222. —T. F. B.

INORGANIC—QUANTITATIVE.

Iodine; Simple method for the determination of — E. Winterstein and E. Herzfeld. Z. physiol. Chem., 1909, 63, 49–51.

THE method proposed consists in acidifying the solution containing the iodine or iodide with phosphoric acid, adding hydrogen peroxide, and heating the solution while a current of air is drawn through it. The air is then passed through a condenser and through two wash-bottles containing a solution of potassium iodide. The iodine carried over with the air is absorbed in the potassium iodide and is subsequently titrated in the usual way. —W. P. S.

Determining hypophosphoric, phosphorous, and hypophosphorous acids in presence of each other and of phosphoric acid. Rosenheim and Pinsker. See VII.

PATENT.

Testing air or gas by means of colour changes of reagents carried on threads. Ger. Pat. 241,893. See XVIII B.

ORGANIC—QUANTITATIVE.

Influence of protein on the determination of rubber as tetrabromide. Spence. See XIII C.

Hard vulcanised rubber. [Determination of sulphur of vulcanisation.] Hübener. See XIII C.

Trade Report.

Netherlands Customs Tariff; Proposed increase of — Board of Trade J., Dec. 2, 1909.

A BILL has been presented to the Second Chamber of the Dutch States General, in which it is provided that from the 1st January, 1910, the Netherlands Customs Tariff is, with certain exceptions, to be increased by 30 per cent.

The exceptions include the following:—

The import duties levied on sugars in virtue of the Sugar Law of the 29th January, 1897, and of the 24th July, 1903, are to remain unchanged.

In the case of the following articles the proposed new rates of duty are as shown below:—

Article.	Rate of Duty.			
	Present.		Proposed.	
Vinegar, including pyro-ligneous acid and acetic acid, crystallised or liquid—	<i>Fls.</i>	<i>cts.</i>	<i>Fls.</i>	<i>cts.</i>
When of a strength of less than 100 grammes of acetic acid per litre, containing no water.....	Per hectolitre.		Per hectolitre.	
	3	00	3	20
When of a strength of 100 grammes of acetic acid per litre, containing no water.....				
	3	50	3	75
If of higher strength proportionately more.				
Acetate of soda—	Per 100 kilograms.		Per 100 kilograms.	
Containing no water....	25	60	28	50
Containing water.....	15	40	17	15
Acetate of calcium—				
Containing no water....	26	60	29	60
Containing water.....	23	80	26	50
	Per hectolitre.		Per hectolitre.	
	3	00	3	50
Beer, including malt extract	Per 100 kilograms.		Per 100 kilograms.	
Salt, refined, and residue of	4	00	4	30

The import duties on chloral hydrate, sulphuric ether, chloroform, acetic ether, sweet spirit of nitre, and all other similar substances prepared from or with alcohol, are to remain unchanged.

British South African trade. Chem. and Drug., Dec. 4, 1909.

THE total imports of drugs, chemicals, &c., into British South Africa during the first six months of 1909 amounted to £379,166, or practically £19,000 more than in the corresponding period last year. Among the items were unenumerated drugs and chemicals £39,267, sodium cyanide 5,389,793 lb. against 3,776,794 lb., caustic soda £7,934, disinfectants £13,683. Glycerin for manufacture advanced from 3,562,997 lb. (£79,262) to 6,063,911 lb. (£130,637), this increase being one of several factors accounting for present famine prices. Sheep-dip is another expanding item, imports having risen in value from £30,757 to £49,145, but toilet soap showed a slight decline of £1,450, the quantity imported being 386,716 lb. The value of explosives imported into the Transvaal advanced from £295,000 to £351,000.

Import Duties of Servia—Minimum rates. Board of Trade J., Dec. 9th, 1909.

A SERVIAN Royal Decree dated the 14th Nov. establishes minimum rates of import duty for certain articles, many of them chemical, which are not covered by any of the commercial treaties which Servia has concluded with other countries. The reduced duties came into force on the 4 17th Nov. and are applicable to the products of the United Kingdom, the British Colonies, and all countries entitled to most favoured nation treatment. A detailed comparative statement of the duties is given.

Books Received.

COAL-TAR AND AMMONIA. By G. LUNGE, Ph.D., Dr. Ing., Prof. Emer. of Technical Chemistry in Federal Polytechnicum, Zürich. Fourth and enlarged edition. Gurney and Jackson, 10 Paternoster Row, London, E.C. 1909. Price 42s. net.

THE work is issued in two 8vo. volumes, containing 1152 pages of subject matter, alphabetical indexes of authors' names and of subjects, and 305 illustrations. Part I. contains:—(1). Introductory. (2). Processes for obtaining coal-tar. (3). Properties of coal-tar and its constituents. (4). Applications of coal-tar without distillation. (5). First distillation of coal-tar. (6). Pitch.

(7). Anthracene oil. (8). Creosote oil. Part II. contains:—(9). Carbofic acid and naphthalene. (10). Light oil and crude naphtha. (11). Working up the light naphtha into final products. (12). Sources from which ammonia is obtained. (13). Composition and analysis of ammoniacal liquor, and properties of its constituents. (14). Working up of ammoniacal liquor. (15). Other technically important ammonium salts. In an appendix there are given tables for reducing specific gravity to normal temperature; for comparing degrees of Baumé's, Cartier's, and Beck's hydrometers with corresponding specific gravities; and for comparing degrees of centigrade and Fahrenheit thermometers.

MANUFACTURE OF SULPHURIC ACID AND ALKALI WITH THE COLLATERAL BRANCHES. Vol. II. SULPHATE OF SODA, HYDROCHLORIC ACID, LEBLANC SODA. By G. LUNGE, Ph.D., Dr. Ing., Prof. Emer. of Technical Chemistry in Federal Polytechnicum, Zürich. Third edition, much enlarged. Gurney and Jackson, 10, Paternoster Row, London, E.C. 1909. Price 42s. net.

THE work is issued in two 8vo. volumes containing 991 pages of subject matter, 335 illustrations, and an alphabetical index. The text is divided as follows:—Part I. Introduction. (1). Properties and occurrence in nature of the raw materials and products of the alkali industry. (2). Analysis of the raw materials and products of the alkali manufacture. (3). Manufacture of sulphate of soda from common salt and sulphuric acid. (4). Manufacture of sulphate of soda by the process of Hargreaves and Robinson. (5). Various methods for the manufacture of sulphate of soda. (6). Purification of sodium sulphate (Glauber's salt); applications. (7). Condensation of the hydrochloric acid produced in the manufacture of sulphate of soda. (8). Manufacture of hydrochloric acid by other than the ordinary methods. (9). Weak acid; control of condensation; yields, costs, purification, pumping and conveyance of hydrochloric acid. Part II. (10). General and historical notes on alkali manufacture; theory of the Le-blanc process. (11). Manufacture of black-ash. (12). Black ash and tank-liquor. (13). Manufacture of finished soda and bicarbonate. (14). Yield and costs. (15). Caustic soda. (16). Tank-waste.

FOOD INSPECTION AND ANALYSIS. By A. E. Leach, S.B. Second edition, revised and enlarged. J. Wiley and Sons, New York. Chapman and Hall, Ltd., London. 1909. Price 31s. 6d. net.

LARGE 8vo volume containing 929 pages of subject matter with 120 illustrations and 40 plates, and an alphabetical index. The text is divided as follows:—(1). Food analysis and official control. (2). The laboratory and its equipment. (3). Food, its functions, proximate components, and nutritive value. (4). General analytical methods. (5). The microscope in food analysis. (6). The refractometer. (7). Milk and milk products. (8). Flesh foods. (9). Eggs. (10). Cereals and their products, legumes, vegetables and fruits. (11). Tea, coffee, and cocoa. (12). Spices. (13). Edible oils and fats. (14). Sugar and saccharine products. (15). Alcoholic beverages. (16). Vinegar. (17). Artificial food colours. (18). Food preservatives. (19). Artificial sweeteners. (20). Flavouring extracts and their substitutes. (21). Canned and bottled vegetables, relishes, and fruit products.

DIAMONDS. By SIR W. CROOKES, LL.D., D.Sc., F.R.S. Harper Bros., London and New York. 1909. Price, Cloth, 2s. 6d.; Leather, 3s. 6d. net.

SMALL 8vo volume containing 140 pages of subject matter, 24 illustrations, and an alphabetical index. The chapter-headings are as follows:—(1). Preliminary. (2). Kimberley and its diamond mines. (3). Kimberley mines at the present day. (4). Collecting the gems. (5). The diamond office. (6). Noteworthy diamonds. (7). Bort, carbonado, and graphite. (8). Physical and chemical properties of the diamond. (9). Genesis of the diamond (including production of artificial diamonds). (10). Natural formation of the diamond. (11). Meteoric diamond.

THE UNIVERSAL STANDARD GRADING OF SCRAP RUBBER.
By ALFRED W. LESLIE, 119, Stoke Newington Road,
London, N. Price 2s. 6d.

Small 8vo volume of 46 pages, subdivided as follows:
(1.) The rise and progress of the rubber industry. (2.)
Scrap rubber generally. (3.) The present position of the
scrap rubber market. (4.) The various grades of scrap
rubber. (5.) Description of the various grades of scrap
rubber. (6.) The prospects of the rubber industry.

DIE ELEKTROMOTORISCHEN KRÄFTE DER POLARISATION,
UND IHRE MESSUNG MIT HILFE DES Oszillographen.
Von M. Le BLANC. Abhandlungen der Deutschen
Bunsen-Ges., Nr. 3. Verlag von W. Knapp, Halle a. S.,
Germany. 1910. Price M.3.

8vo. volume containing 79 pages of subject matter and
88 illustrations.

BEITRÄGE ZU EINER KOLLOIDCHEMIE DES LEBENS. Von
R. E. LIESEGANG. Verlag von T. Steinkopf, Dresden,
Germany. 1909. Price M. 4; bound, M.5.

The work consists mainly of discussions of and deductions
from, the phenomena due to diffusion, chemical reactions
and physical actions in jellies.

COMPLETE SPECIFICATIONS ACCEPTED.

- 24,483 (1908). Grossmann. Centrifugal apparatus for
separating solids from liquids. Dec. 22.
26,152 (1908). Hommel, and Metals Extraction Cor-
poration. Apparatus for use in solution and precipitation
processes, particularly for extracting zinc. Dec. 15.
26,381 (1908). Down. Process and apparatus for mixing
substances. Dec. 15.
26,537 (1908). Suzuki. Continuous evaporators for
liquids which deposit crystals. Dec. 8.
26,577 (1908) and 13,338 (1909). Traut. Manufacture of
vessels capable of resisting chemical action. Dec. 15.
26,684 (1908). Sprague. Treatment of corrosive gaseous
fumes or smoke. Dec. 15.
779 (1909). Brucke. Distilling, evaporating, heating,
or cooling liquids. Dec. 8.
1,650 (1909). Delporte. Agglomerating or hardening
pulverulent, finely-divided, and friable substances. Dec. 8.
6,561 (1909). Friedrich. Regenerative reverberatory
furnaces. Dec. 8.
9,146 (1909). Cie. Indus. des Alcools de l'Ardeche.
Use of treated sawdust as an absorbent. Dec. 22.
9,158 (1909). Weeks. *See under X.*
20,215 (1909). Brun. Lined preparations for use in
steam generators. Dec. 8.
22,163 (1909). Hodgkinson. *See under VII.*

II.—FUEL, GAS, AND LIGHT.

APPLICATIONS.

- 27,828. Pringle and Richards. Carbonisation of coal and
other carbonaceous material. Nov. 29.
27,829. Pringle and Richards. Production of smokeless
briquettes from coal. Nov. 29.
27,960. Lake (Hite). Manufacture of coal briquettes.*
Nov. 30.
28,048. Franke. Manufacture of briquettes of porous
hygroscopic fuels. [Ger. Appl., April 26, 1909.]* Dec. 1.
28,054. Moores. Composition for purifying gas from
oils and spirits.* Dec. 1.
28,467. Dieker (Underfeed Stoker Co.). *See under*
XXIII.
28,692. Dukes (Ges. f. Verwertungs Chem. Produkte).
Manufacture of metallic incandescent bodies for electric
lamps. Dec. 8.
28,868. Radcliffe. Recovery of ammonia from distilla-
tion gases. Dec. 10.
29,029. Lake (Hydrocarbon Converter Co.). Manufac-
ture of gas from hydrocarbon oils, &c.* Dec. 11.
29,125. Johnson (Maschinen u. Armaturen Fabr. vorm.
Breuer und Co.). Apparatus for making gas by dis-
tilling coal.* Dec. 13.
29,149. Radcliffe. Purification of condensation products
from producer gas manufacture. Dec. 14.
29,313. Smith and Shaw. Vertical gas retorts. Dec. 15.
29,328. Ruthenberg. Distillation of coal and like
material. Dec. 15.
29,559. Stephen. Manufacture of artificial fuel. Dec. 17.

COMPLETE SPECIFICATIONS ACCEPTED.

- 23,044 (1908). Wilton. Gas generators, producers, or
refuse destructors. Dec. 8.
23,263 (1908). Meunier. Gas manufacture. Dec. 8.
26,146 (1908). Lemonli, and Poulenc freres. *See under*
XXIII.
26,387 (1908). Garzón. Apparatus for utilising tar as
liquid fuel. Dec. 5.
27,718 (1908). Variens. Production of a gas under
pressure for motive power. Dec. 22.
27,755 (1908). Zdanowich. Incandescent mantles.
Dec. 22.
2113 (1909). Davis. Gas washers. Dec. 8.
2495 (1909). Chapman. Gas producers. Dec. 22.
3981 (1909). Gutensohn. Manufacture of combustible
briquettes. Dec. 15.
6958 (1909). Korthing, Jaentsch, and Sauer. Manufacture
of peat bricks, &c. Dec. 8.

Patent List.

Where a Complete Specification accompanies an Application, an
asterisk is affixed. The dates given are (i) in the case of Applica-
tions for Patents, the dates of Application, and (ii) in the case of
Complete Specifications Accepted, those of the Official Journals
in which acceptances of the Complete Specifications are advertised.

Complete Specifications thus advertised as accepted are open to
inspection at the Patent Office immediately, and to opposition
within two months of the said dates.

I.—PLANT, APPARATUS, AND MACHINERY.

APPLICATIONS.

- 27,938. Clark (Ges. der Tentelwischen Chem. Fabr.).
Process and apparatus for cooling water.* Nov. 30.
28,047. Franke. Manufacture of plastic articles of
hygroscopic materials.* Dec. 1.
28,242. Miller. Filters. [U.S. Appl., Jan. 22, 1908.]*
Dec. 3.
28,302. Vialleix and Perrin. *See under VII.*
28,360. Abresch. Device for filtering and purifying
liquids.* Dec. 4.
28,625. Justice (Binney). *See under X.*
28,720 and 28,721. Brown and Fawns. Utilisation of
ammonia as a motive power source of energy, &c. Dec. 8.
28,798. Breakell. *See under X.*
28,829. Glass. Forming materials into briquettes.
Dec. 9.
28,836. Boulton (Low). Centrifugal separating appara-
tus.* Dec. 9.
28,945. Breakell. Apparatus for separating liquids from
materials and for washing and saturating materials with
liquid. Dec. 10.
29,104. Edmonds. Hydro-extractors. Dec. 13.
29,360. Willey Mining Machinery Co., and Roberts.
Filtering apparatus. Dec. 15.
29,371. Haddan (Act.-Ges. f. Autogene Aluminium
Schweissung). Vessels lined with aluminium for liquids,
gases, &c. Dec. 15.
29,394. Parouty-Dupont and Mureret. Distilling
apparatus. Dec. 15.
29,445. Drucker. Continuous slimes vacuum filter.
Dec. 16.
29,549. Macfarlane. Centrifugal drying machines.
Dec. 17.
29,698. Scott and Co., Ltd., and Pooley. Evaporating
apparatus. Dec. 18.

12,363 (1909). Koppers. Coking and gas generating ovens. Dec. 15.

16,328 (1909). Weber. Manufacture of electric incandescent lamp filaments. Dec. 15.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

APPLICATIONS.

27,714. Fabbri. Treatment of mineral and like oils. Nov. 29.

COMPLETE SPECIFICATION ACCEPTED.

26,296 (1908). Lodigiani. Obtaining strong aqueous solutions of creosote. Dec. 8.

IV.—COLOURING MATTERS AND DYESTUFFS.

APPLICATIONS.

27,773. Newton (Bayer and Co.). Manufacture of vat dyestuffs. [Addition to No. 7,819 of 1909.]* Nov. 29.

28,042. Johnson (Badische Anilin und Soda Fabrik). Production of halogen derivatives of indigo. Dec. 1.

28,043. Newton (Bayer and Co.). Manufacture of vat dyestuffs. [Addition to No. 7,819 of 1909.] Dec. 1.

28,170. Meister, Lucius, und Brüning. Manufacture of vat dyestuffs. [Addition to No. 16,584 of 1907. Ger. Appl., Dec. 24, 1908.]* Dec. 2.

28,171. Meister, Lucius, und Brüning. Manufacture of penta- and hexa-halogenised indigos. [Comprised in No. 3,019 Feb. 8, 1909.] Dec. 2.

28,716 and 28,717. Newton (Bayer and Co.). Manufacture of azo dyestuffs. Dec. 8.

28,718. Newton (Bayer and Co.). Manufacture of polyazo dyes. Dec. 8.

29,112. Bloxam (Act.-Ges. f. Anilinfabr.). Manufacture of thio-derivatives of diarylamines, their homologues and analogues. Dec. 13.

29,138. Newton (Bayer and Co.). Manufacture of anthracene derivatives. [Addition to No. 2,702 of 1909.] Dec. 13.

29,139. Newton (Bayer and Co.). Manufacture of derivatives of the anthraquinone series. Dec. 13.

29,458 and 29,459. Newton (Bayer and Co.). Manufacture of azo dyestuffs. Dec. 16.

29,674. Bloxam (Act.-Ges. f. Anilinfabr.). Manufacture of a yellow monoazo dyestuff for wool. Dec. 18.

29,675. Bloxam (Act.-Ges. f. Anilinfabr.). Manufacture of a monoazo dyestuff and colour lakes therefrom. Dec. 18.

COMPLETE SPECIFICATIONS ACCEPTED.

26,023 (1908). Newton (Bayer and Co.). Manufacture of azo dyestuffs. Dec. 8.

5,383 (1909). Newton (Bayer and Co.). Manufacture of azo dyestuffs. Dec. 8.

5,558 (1909). Imray (Meister, Lucius, und Brüning). Manufacture of leuco-bodies of dyestuffs, containing sulphur. Dec. 22.

7,819 (1909). Newton (Bayer and Co.). Manufacture of vat dyestuffs. Dec. 15.

8,438 (1909). Dreyfus, Tompkins, and Clayton Aniline Co. Manufacture of halogenated compounds of indigo and indigoid bodies. Dec. 15.

17,265 (1909). Meister, Lucius, und Brüning. Manufacture of vat dyestuffs. Dec. 8.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

APPLICATIONS.

27,731. Heap. Machinery for washing, bleaching, dyeing, and drying yarn. Nov. 29.

27,738. Denman. Colour printing on fabrics, &c. Nov. 29.

28,126. Schiffers. Machines for dyeing, bleaching, &c., textile fabrics or goods.* Dec. 2.

28,256. Friedrich. Production of fine artificial threads. [Ger. Appl., Dec. 3, 1908.]* Dec. 3.

28,791. Stark. Preparing brittle vegetable fibres for spinning and dyeing of capoe, akone kalotropis procera and the like. Dec. 8.

28,737. Turner and Maxwell. Bleaching processes. Dec. 8.

28,828. Mitchell. Manufacture of printed felts. Dec. 9.

29,209. Jacques, Filburn, and Abrahams. Rendering flannelette and other fabrics non-inflammable. Dec. 14.

29,266. Bauartikel-Fabr. A. Siebel. Manufacture of waterproof materials. [Ger. Appl., Mar. 3, 1909.]* Dec. 14.

29,314. Appleyard. Dyeing and printing with vat-dyeing colours. Dec. 15.

COMPLETE SPECIFICATIONS ACCEPTED.

27,123 (1908). Claviez. Manufacture of a material adapted to be spun. Dec. 22.

28,042 (1908). Hardman and Edmondson. Bleaching cotton and other vegetable fibres. Dec. 8.

1,227 (1909). Newton (Bayer and Co.). Production of black shades on cotton. Dec. 22.

6,554 (1909). Schloss, and Fürst Guido Donnersmarck'sche Kunstseiden- u. Acetatwerke. *See under XIX.*

8,744 (1909). Allsop and Sibson. Dyeing and washing machine. Dec. 8.

11,729 (1909). Chem. Fabr. Griesheim Elektron. Treatment of mercerised cotton goods. Dec. 8.

VII.—ACIDS, ALKALIS, AND SALTS.

APPLICATIONS.

27,826. Häusser. Manufacture of nitrogen oxides.* Nov. 29.

28,302. Vialleix and Perrin. Condensing acid vapours. [Fr. Appl., Dec. 4, 1908.]* Dec. 3.

28,364. Radcliffe. Purification of ammonia waste liquid. Dec. 4.

28,391. Burkhardt. Forming semi-liquid quartz.* Dec. 6.

28,609. Glaser and Müller. Refining salt and recovering its impurities.* Dec. 7.

28,610. Teed, Sulman, and Picard. Recovery of sulphur from gases. Dec. 7.

28,629. Lead Products Synd., and Thompson. Manufacture of lead oxide. Dec. 7.

28,665. Laverty. Lime-burning and lime-gas producing kilns. Dec. 8.

28,703. Güntersohn. Treatment of nitric cake. Dec. 8.

28,755. Von Schlippenbach. Recovering gases rich in sulphur dioxide from gases poor therein in roasting and oxidising processes. [Ger. Appl., May 24, 1909.]* Dec. 8.

29,294. Greenwood. Extraction of arsenic from arsenical residue. Dec. 15.

29,385. Friedrich. Manufacture of a copper salt specially suited for preparing ammoniacal copper oxide. [Ger. Appl., Dec. 15, 1908.]* Dec. 15.

29,491. Chem. Fabr. Griesheim Elektron. Manufacture of anhydrous caustic soda. [Ger. Appl., Dec. 23, 1908.]* Dec. 16.

29,494. Chem. Fabr. Griesheim Elektron. Manufacture of anhydrous caustic potash. [Addition to No. 29,491 of 1909. Ger. Appl., March 26, 1909.]* Dec. 16.

29,669. Von Schmoll. Production of a solution of water glass.* Dec. 18.

COMPLETE SPECIFICATIONS ACCEPTED.

23,385 (1908). Salpetersäure. Ind. Ges. Manufacture of nitric acid from mixtures of nitrogenous gases and water. Dec. 15.

23,676 (1908). Sarason. Increasing the keeping quality of compounds containing unstable oxygen. Dec. 15.

23,689 (1908). Vourasos. Decomposition of metal chlorides. Dec. 15.

26,258 (1908). Eckford. *See under XIII.*

- 26,720 (1908). Hazard-Flamand. Dividing air into its elements by fractional distillation. Dec. 15.
 26,826 (1908). British Thomson-Houston Co. (General Electric Co.). *See under X.*
 28,112 (1908). Behrens. Separating carbonic acid from gas mixtures. Dec. 8.
 1585 (1909). Carulla. Manufacture of ammonium salts and iron oxide from ferrous liquors. Dec. 22.
 10,591 (1909). Aktiebolaget Swedish Nitric Syndicate. Continuous concentration of acids. Dec. 22.
 14,835 (1909). Erbslow and Condron. *See under XIII.*
 17,690 (1909). Coulier. Manufacture of alkaline earth sulphates. Dec. 8.
 22,163 (1909). Hodgkinson. Apparatus for evaporating brine or other solutions. Dec. 8.

VIII.—GLASS, POTTERY, AND ENAMELS.

APPLICATION.

- 29,694. Westacott. Treatment of china clay. Dec. 18.
 COMPLETE SPECIFICATIONS ACCEPTED.
 18,322 (1909). Quertinmont. Apparatus for making sheet or plate glass. Dec. 8.
 18,323 (1909). Quertinmont. Manufacture of glass. Dec. 8.
 18,713 (1909). Voelker. Forming bodies of semi-liquid quartz and like material. Dec. 22.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

APPLICATION.

- 28,798. Breakell. *See under X.*
 COMPLETE APPLICATIONS ACCEPTED.
 118 (1909). Stein. Producing granulated slag from refuse for artificial stone. Dec. 22.
 1,844 (1909). Poulson. Manufacture of refractory bricks and treatment of moulders' sand. Dec. 22.
 11,637 (1909). Tabourin. Manufacture of flag-stones, tiles, &c., of cement. Dec. 15.
 15,165 (1909). Metzger. Machines for treating blast-furnace slag in making cement. Dec. 8.

X.—METALS AND METALLURGY.

APPLICATIONS.

- 27,806. Ramage. Recovery of iron from ores and preparing iron alloys.* Nov. 29.
 28,099. Bliss. Drying air for metallurgical furnaces. Dec. 2.
 28,131. Coslett. Treatment of iron or steel to prevent oxidation or rusting. Dec. 2.
 28,487. Imbert Process Co. Extraction of zinc from zinc ores. [Fr. Appl., Dec. 24, 1908.]* Dec. 6.
 28,608. Rübel. Manufacture of a metal of low specific weight. Dec. 7.
 28,611. Hommel and Durant. Extraction of zinc and copper from ores. Dec. 7.
 28,612. Sulman and Picard. Treatment of oxidised ores, &c. Dec. 7.
 28,625. Justice (Binney). Filters for metallurgical and other uses. Dec. 7.
 28,798. Breakell. Apparatus for pulverising ores, cement, phosphates, &c. Dec. 9.
 28,901. Beauchamp. Using sulphurous gases directly on ores. Dec. 10.
 28,933. Sulman, Picard, and Ballot. Concentration of ores. Dec. 10.
 29,076. Reynolds. Manufacture of crucible steel. Dec. 13.
 29,286 and 29,287. McKechnie and Beasley. Separation of metals from ores, residues, &c. Dec. 14.
 29,331. Gutensohn. Treatment of zinc lead ore. Dec. 15.
 29,332. Gutensohn. Production of briquettes from metal oxides and ore. Dec. 15.

- 29,364. Sulman and Picard. Flotation treatment of ores. Dec. 15.
 29,365. Buderus'sche Eisenwerke. Apparatus for atomising liquid slag. [Ger. Appl., Dec. 28, 1908.]* Dec. 15.
 29,392. Bradley and Williams. Extraction of metals from ores. Dec. 15.
 29,482. Reynolds. Manufacture of steel.* Dec. 16.
 29,597. Girod. Hardening projectiles or other steel articles. [Fr. Appl., Jan. 23, 1909.]* Dec. 17.
 29,616. Sulman and Picard. Flotation treatment of ores. Dec. 17.

COMPLETE SPECIFICATIONS ACCEPTED.

- 18,175 (1908). Hodgkinson and Peck. Production of copper alloys. Dec. 8.
 21,759 (1908). Hommel, and Metals Extraction Corporation. Extraction of zinc from its ores or compounds. Dec. 22.
 21,837 (1908). Junqueras. Treatment of minerals for the extraction of metal. Dec. 22.
 22,873 (1908). Siemens und Halske A.-G. Production of tantalum. Dec. 8.
 23,179 (1908). De St. Seine, and Thwaites Bros. Furnaces for smelting ores, residues, &c., to obtain copper and other metals. Dec. 8.
 26,152 (1908). Hommel, and Metals Extraction Corporation. *See under I.*
 26,264 (1908) and 8,287 (1909). Lockwood and Samuel. Oils and oily liquids for use in treating ores, and also the treatment of ores. Dec. 8.
 26,380 (1908). Landenberger. Manufacture of alloys. Dec. 15.
 26,711 (1908). Williams and Bradley. Obtaining zinc and copper from complex ores, &c. Dec. 22.
 26,826 (1908). British Thomson-Houston Co. (General Electric Co.). Silicon alloys. Dec. 8.
 26,831 (1908). Williams. Lixivation processes for the extraction of metals. Dec. 15.
 27,353 (1908). Bloxam (Cie. des Forges de Chatillon Commeny et Neufves-Maisons). Pickling metals. Dec. 22.
 28,003 (1908). Soc. Anon. La Néo-Metallurgie. Manufacture of commercially pure carburetted manganese. Dec. 22.
 1,365 (1909). Barclay and Rodgers. Alloys known as German silver. Dec. 15.
 8,778 (1909). Schoop. Welding objects of aluminium or aluminium alloys. Dec. 8.
 9,158 (1909). Weeks. Apparatus for calcining, desulphurising, and sintering ores and like materials.* Dec. 8.
 16,229 (1909). Lockwood and Samuel. Treatment of ores. Dec. 8.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

APPLICATIONS.

- 27,972. Hay. Electric furnaces. [U.S. Appl., June 19, 1909.]* Nov. 30.
 28,552. Hartmann. Purification of liquids by electricity.* Dec. 7.
 28,813. Wassmer. Electric furnaces. Dec. 9.
 29,214. Cowper-Coles. Electrodeposition of iron. Dec. 14.
 29,228. Soc. Ind. de l'Accu-Mixte l'Energique. Manufacture of accumulator plates. [Fr. Appl. Dec. 14, 1908.]* Dec. 14.
 29,671. Vogel. Electric furnaces.* Dec. 18.

COMPLETE SPECIFICATIONS ACCEPTED.

- 27,107 (1908). Skelton. Ozonisers. Dec. 22.
 7,338 (1909). Nya Aekumulator Aktiebolaget Jungner and others. Active mass for negative electrodes of electric elements with alkaline electrolyte. Dec. 22.

16,225 (1909). Bunet and Badin. Apparatus for producing electric arcs for the formation of compounds of oxygen and nitrogen. Dec. 15.
 17,342 (1909). Aktiebolaget Elektrometall. Electric furnaces. Dec. 15.

XII.—FATTY OILS, FATS, WAXES, AND SOAPS.

APPLICATIONS.

27,899. Higgins and Spensley. Drying or stoving soap. Nov. 30.
 28,098. Tweedale. Soap. Dec. 2.
 28,436. Von Romocki. Manufacture of soaps and the like. Dec. 6.
 29,113. Muller. Manufacture of Soap. Dec. 13.
 29,438. McDonald. *See under* XVIII.4.

COMPLETE SPECIFICATIONS ACCEPTED.

26,264 (1908) and 8,287 (1909). Lockwood and Samuel. *See under* X.
 27,083 (1908). Buchanan. Manufacture of soap. Dec. 22

XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, &c.

(A.)—PIGMENTS, PAINTS.

APPLICATIONS.

28,490. Rehkop. Burning ultramarine in crucibles adapted to be closed by coverlets.* Dec. 6.
 29,675. Bloxam (Act.-Ges. f. Anilinfabr.). *See under* IV.

COMPLETE SPECIFICATIONS ACCEPTED.

26,258 (1908) and 15,423 (1909). Eckford. Manufacture of red lead. Dec. 15.
 14,835 (1909). Erbslow and Condron. Manufacture of white lead. Dec. 8.

(C.)—INDIA-RUBBER.

APPLICATIONS.

27,908. Woltereck. *See under* XX.
 28,613. Grist. Production of rubber. Dec. 7.
 28,788. Matthews and Strange. Synthetic manufacture of caoutchouc, &c. Dec. 9.
 28,878. Prestwich. Cellular india-rubber substitute. Dec. 10.
 29,277. Lilley. Production of a synthetic rubber or rubber-like material. Dec. 14.
 29,565. Matthews and Strange. Manufacture of compounds analogous to caoutchouc. Dec. 17.
 29,566. Matthews and Strange. Manufacture of caoutchouc. Dec. 17.

COMPLETE SPECIFICATIONS ACCEPTED.

27,688 (1908). Wallace and Reynaud. Manufacture of elastic or plastic products similar to caoutchouc. Dec. 22.
 4154 (1909). Commercial Products Co. (Berend). Production of a plastic and elastic substance. Dec. 15.
 8062 (1909). Dogny, Henri, and Veil-Pickard. Manufacture of products from india-rubber or similar material. Dec. 8.

XIV.—TANNING, LEATHER, GLUE, SIZE, &c.

APPLICATION.

28,297. Utley. Clarifying and decolorising gelatin and glue liquors. [U.S. Appl., Dec. 12, 1908.]* Dec. 3.

COMPLETE SPECIFICATIONS ACCEPTED.

18,411 (1909). Cave-Brown-Cave. Treatment of leather, fur skins, and the like. Dec. 22.

XVI.—SUGAR, STARCH, GUM, &c.

APPLICATION.

28,742. Wolf. Production of artificial honey liquid, refined sugar or fructose, and white sugar from beet, raw, or crude sugar. [Ger. Appl., Dec. 8, 1908.]* Dec. 8.

XVII.—BREWING, WINES, SPIRITS, &c.

APPLICATIONS.

27,713. Fabbri. Obtaining a greater production of ethyl alcohol from maize, grain, molasses, coal, &c. Nov. 29.
 27,831. Kuhn. Manufacture of grape beer. [Fr. Appl., Dec. 2, 1908.]* Nov. 29.
 27,977. Epstein. Treatment of lactobacilline or paracetic culture or fermentation or the like. Nov. 30.
 28,561. Berliner A.-G. f. Eisengiesserei. Malt drums. [Ger. Appl., Dec. 8, 1908.]* Dec. 7.
 29,114. Braasch. Production of yeast. [Addition to No. 10,458 of 1909. Ger. Appl., Dec. 21, 1908.]* Dec. 13.
 29,232. Epstein. Treatments of fermentation or culture or the like. Dec. 14.
 29,379. Sureties. Solidifying brewers' yeast. Dec. 15.
 29,534. Parkhurst and West. Treatment of liquids during fermentation. Dec. 17.

COMPLETE SPECIFICATIONS ACCEPTED.

24,592 (1908). Barr. Production of ferments. Dec. 22.
 24,300 (1909). Smith. Process of making extract of hops. Dec. 15.

XVIII.—FOODS; SANITATION, WATER PURIFICATION; AND DISINFECTANTS.

(A.)—FOODS.

APPLICATIONS.

27,722 and 27,723. Bond and Collett. Utilising whey for dietetic purposes. Nov. 29.
 27,775. Johnson (Chem. Fabr. vorm. Goldenburg, Geromont, und Co.). Manufacture of baking powder.* Nov. 29.
 27,798. Henri, Helbronner, and von Recklinghausen. Sterilising water and other liquids and ferments. Nov. 29.
 28,150. Gottsleben. Production of a soluble powder from egg yolks. Dec. 2.
 28,371. Stohr. Manufacture of milk-food preparations.* Dec. 4.
 29,438. MacDonald. Manufacture of feeding cakes for animals and extracting oil from the seeds used. Dec. 16.

COMPLETE SPECIFICATIONS ACCEPTED.

23,585 (1908). Sleeman. Digestive ferments and method of preparing them. Dec. 15.
 25,501 (1908). Yeo, Hall, and Goskar. Aeration of liquids and manufacture of mineral waters. Dec. 8.
 26,939 (1908). Soc. Anon. des Tabacs Desintoxiqués. Removing nicotine from tobacco. Dec. 22.

(B.)—SANITATION; WATER PURIFICATION.

APPLICATIONS.

28,516. Grossmann. Drying sewage sludge. Dec. 7.
 29,032. Guy. Bacteria beds or filter beds. Dec. 11.
 COMPLETE SPECIFICATIONS ACCEPTED.
 23,044 (1908). Wilton. *See under* II.
 27,226 (1908). Ozonair, Ltd., and Joseph. Sterilisation of water by ozonisation. Dec. 15.
 7464 (1909). Leigh. Treatment of fluids in filter beds. Dec. 15.
 12,246 (1909). Marks (Desceniss und Jacobi). Freeing water from iron. Dec. 8.

NIX.—PAPER, PASTEBOARD, &c.

APPLICATIONS.

- 27,950. Wilbuschewitsch. Making paper or cardboard from the husks of cotton seeds.* Nov. 30.
 28,165. Pearson and Stoncham. Manufacture of fibre board. Dec. 2.
 28,343. Leachman. Finishing paper and like materials. Dec. 4.
 29,480. Kuess. Manufacture of paper pulp from the fruit of trees of the coconut tribe. [Appl. in Tunis, April 8, 1909.]* Dec. 16.
 29,514. Hankey. Preparation and treatment of drawing paper. Dec. 16.
 29,553. White and Gray. Towers for bleaching paper pulp.* Dec. 17.

COMPLETE SPECIFICATIONS ACCEPTED.

- 6554 (1909). Schloss, and Fürst Guido Donner-smarek'sche Kunstseiden u. Acetatwerke. Manufacture of solutions of cellulose acetate. Dec. 8.
 15,281 (1909). Brandenberger. Manufacture of cellulose films. Dec. 15.

XX.—FINE CHEMICALS, ALKALOIDS,
ESSENTIAL OILS, AND EXTRACTS.

APPLICATIONS.

- 27,908. Wolterreck. Production of isoprene. Nov. 30.
 28,044 and 28,045. Newton (Bayer und Co.). Manufacture of pharmaceutical compounds. Dec. 1.
 28,166. Newton (Bayer und Co.). Manufacture of pharmaceutical compounds. Dec. 2.
 28,182. Neumann. Treatment of hæmoglobin.* Dec. 2.
 28,361. Bloxam (Act.-Ges. f. Anilinfabr.). Manufacture of *p*-aminophenylarsinic acid. Dec. 4.
 28,383. Wootton. Preparation of alkyl and aryl amino-derivatives of camphoric acid. Dec. 4.
 28,618. Criquebeuf and Helbronner. Production of a liquid rich in methyl acetate. Dec. 7.
 28,715 and 28,719. Newton (Bayer und Co.). Manufacture of pharmaceutical products. Dec. 8.
 29,247. Merck. Preparation of concentrated solutions of thiosinamine. [Addition to No. 22,533 of 1905. Ger. Appl., Feb. 27, 1909.]* Dec. 14.
 29,439. Richter. Alkaline salts of acetylsalicylic acid.* Dec. 16.
 29,647. Kipping. Synthesis of organic compounds. Dec. 18.

COMPLETE SPECIFICATIONS ACCEPTED.

- 26,708 (1908). Zimmermann (Chem. Fabr. auf Actien, vorm. E. Schering). Manufacture of camphor. Dec. 15.

- 1561 (1909). Wellcome and Barger. Synthesis of a physiologically active base. Dec. 8.
 12,745 (1909). Wetter (Hoffmann-La Roche und Co.). Manufacture of guaiacolsulphonic acid and its salts. Dec. 22.

XXI.—PHOTOGRAPHIC MATERIALS AND
PROCESSES.

APPLICATIONS.

- 27,818. Tauleigne and Mazo. Photography in colours. Nov. 29.
 29,273. Soc. Anon. des Plaques et Papiers Photographiques A. Lumière et ses fils. Manufacture of polychrome surfaces for colour photography. [Fr. Appl., Feb. 6, 1909.]* Dec. 14.
 29,460. Newton (Bayer und Co.). Transfer pictures. Dec. 16.

COMPLETE SPECIFICATIONS ACCEPTED.

- 27,233 (1908). Mansell and Mansell. Production and reproduction of bleached images. Dec. 15.
 7932 (1909). Rieder. Photographic powdering process. Dec. 22.
 14,243 (1909). Ives. Sensitised plates for use in three-colour photography. Dec. 22.

XXII.—EXPLOSIVES, MATCHES, &c.

APPLICATIONS.

- 28,237. Gabbett-Fairfax, Sankey, and Smith. Explosives. Dec. 2.
 28,600. Hale. Manufacture of explosives. Dec. 7.
 28,929. Delvigne. Explosives. [Belg. Appl., April 2, 1909.]* Dec. 10.

XXIII.—GENERAL ANALYTICAL CHEMISTRY.

APPLICATION.

- 28,467. Dieker (Underfeed Stoker Co. of America). Analysis of gas.* Dec. 6.

COMPLETE SPECIFICATION ACCEPTED.

- 26,146 (1908). Lemoult, and Poulenc frères. Apparatus for determining the calorific power and composition of gaseous combustibles. Dec. 15.
 26,561 (1908). Hinman. Means for measuring or analysing mixtures. Dec. 8.

LIST OF COUNCIL AND OFFICERS.

President.

Prof. R. Meldola, F.R.S., 6, Brunswick Square, London, W.C.

Vice-Presidents.

Enstace Carey, The Groves, Grassendale Park, near Liverpool.

Dr. Edw. Divers, F.R.S., 3, Canning Place, Palace Gate, London, W.

Dr. J. T. Dunn, 10, Dean Street, Newcastle-on-Tyne.

Prof. Percy F. Frankland, The University, Birmingham.

A. R. Ling, Hazeldene, Kingston Road, New Malden.

Sir Boverton Redwood, 4, Bishopsgate Street Within, London, E.C.

Walter F. Reid, Fieldside, Addlestone, Surrey.

A. Gordon Salamon, 1, Fenchurch Avenue, London, E.C.

George C. Stone, New Jersey Zinc Co., 71, Broadway, New York City, U.S.A.

Dr. T. B. Wagner, 14, Marquette Terrace, Chicago, Ill., U.S.A.

Charles Wightman, 1, Fenchurch Avenue, London, E.C.

R. C. Woodcock, c/o The Sanitas Co., Locksley Street, Limehouse, E.

Ordinary Members of Council.

Prof. P. Phillips Bedson, Armstrong College, Newcastle-on-Tyne.

Prof. W. Hodgson Ellis, Faculty of Applied Science, University of Toronto, Canada.

Oscar Guttman, 60, Mark Lane, London, E.C.

Henry Hemingway, 9, Albemarle Mansions, Hampstead, N.W.

Prof. G. G. Henderson, Technical College, Glasgow.

Prof. W. R. E. Hodgkinson, 89, Shooter's Hill Road, Blackheath, S.E.

E. Grant Hooper, 16, Royal Avenue, Sloano Square, London, S.W.

Dr. Charles A. Keane, 119, Ladbroke Road, London, W.

C. T. Kingzett, Newlands, St. George's Avenue, Weybridge.

Frank H. Tate, 9, Haekins Hey, Liverpool.

Dr. L. T. Thorne, 2, Denbigh Gardens, Richmond.

Harold Van der Linde, c/o Continental Rubber Co., 411, Broadway, New York City, U.S.A.

Chairmen and Secretaries of Sections (Ex-officio Members of Council).

Birmingham :

Chairman .. Harry Silvester, 78, Holyhead Road, Handsworth, Birmingham.

Secretary .. F. R. O'Shaughnessy, Tyburn, near Birmingham.

Canadian :

Chairman .. Dr. Milton L. Hersey, P.O. Box 554, Montreal, Canada.

Secretary .. Alf. Burton, 44, York Street, Toronto, Canada.

Liverpool :

Chairman .. Max Muspratt, The Grange, Fulwood Park, Liverpool.

Secretary .. W. Roscoe Hardwick, 13, Batavia Buildings, Harkins Hey, Liverpool.

London :

Chairman .. Dr. J. Lewkowitsch, 71, Priory Road, N.W.

Secretary .. Julian L. Baker, Stainesbury Holt, Kingston Road, Staines.

Manchester :

Chairman ..

Secretary .. Julius Hübner, Ash Villa, Cheddle Hulme, Cheshire.

Newcastle :

Chairman .. Charles J. Potter, Heaton Hall, Newcastle-on-Tyne.

Secretary .. Dr. F. C. Garrett, Armstrong College, Newcastle-on-Tyne.

New England :

Chairman .. F. E. Atteaux, 176, Purchase Street, Boston, Mass., U.S.A.

Secretary .. Alan A. Cladin, 88, Broad Street, Boston, Mass., U.S.A.

New York :

Chairman .. Maximilian Toch, 329, Fifth Avenue, New York City, U.S.A.

Secretary .. Dr. H. Schweitzer, 117, Hudson Street, New York City, U.S.A.

Nottingham :

Chairman .. Oliver Quibell, Shalem Lodge, Newark-on-Trent.

Secretary .. S. R. Trotman, City Laboratories, 1, Regent Street, Nottingham.

Scotland :

Chairman .. D. J. Playfair, 7, Victoria Crescent, Dowanhill, Glasgow.

Secretary .. Dr. G. B. Neave, Technical College, Glasgow.

Sydney, N.S.W. :

Chairman .. Prof. J. A. Schofield, The University, Sydney.

Secretary .. T. F. Walton, Colonial Sugar Refining Co., O'Connell Street, Sydney.

Yorkshire :

Chairman .. Prof. W. M. Gardner, Technical College, Bradford.

Secretary .. Thos. Fairley, 17, East Parade, Leeds.

Honorary Treasurer.

Thomas Tyrer, Stirling Chemical Works, Stratford, London, E.

Honorary Foreign Secretary.

Dr. Ludwig Mond, F.R.S., 20, Avenue Road, Regent's Park, London, N.W.

General Secretary.

Chas. G. Cresswell, Palace Chambers, Westminster, S.W. (Telegraphic address:—59, Palatable, London, Telephone No. 715, Victoria.)

Editor.

Watson Smith, 34, Upper Park Road, Haverstock Hill, London, N.W.

LIST OF MEMBERS.

THE MEMBERSHIP ON FEBRUARY 27, 1909 = 4258.

NOTE: "O.M." MEANS "ORIGINAL MEMBER."

A

1908. Abelli, Dr. Modesto, Avigliana, Torino, Italy, Director of Nobel Explosive Works.
1903. Abraham, Herbert, 13, West 80th Street, New York City, U.S.A., Chemist.
1902. Acker, Chas. E., 1, West 121st Street, New York City, U.S.A., Manufacturer.
1903. Ackermann, Franz W., Hudson Heights, N.J., U.S.A., Chemist.
1909. Acott, Richard H., c/o Porter Fibre Bottle Co., Lewiston, N.Y., U.S.A., Chemist.
1903. Acton, J. Rowland, India Store Depot, Belvedere Road, London, S.E., Civil Servant.
1907. Adam, Wm. A., c/o Mauder Bros., Wolverhampton, Chemist.
1892. Adams, Arthur, Kelvin House, Edgbaston Road, Smethwick, near Birmingham, Science Lecturer.
1897. Adams, Thos. H., Endon Villa, Victoria Avenue, Borrowash, near Derby, Analyst.
1895. Adamson, G. P., c/o The Baker and Adamson Chemical Co., Easton, Pa., U.S.A., Manufacturing Chemist.
1891. Adcock, S. R., St. Helens Smelting Co., Atlas Court, St. Helens, Lancashire, Analytical Chemist.
1901. Addison, Leonard, c/o Messrs. Burt, Boulton, and Haywood, Selzaete, Belgium, Chemist.
1898. Adgate, M., Nangatuek, Conn., U.S.A., Chemist.
1896. Adler, Dr. Leon N., Adler Colour and Chemical Works, 100, William Street, New York City, U.S.A., Manufacturing Chemist.
1907. Adley, Geo. S., Storer's Wharf, Poplar, London, E., Varnish Manufacturer.
1888. Adriance, Dr. John S., The Union League Club, New York City, U.S.A., Analytical Chemist.
1899. Adrot, Léon, Woodside, Long Island, N.Y., U.S.A., Chemist.
1891. Airedale, Rt. Hon. Lord, Gledhow Hall, and (Jnls.) Monkbridge Iron and Steel Co., Ltd., Leeds, Iron and Steel Manufacturer.
1886. Aitken, J. B., Gerard's Fold Chemical Works, Widnes, Chemical Manufacturer.
1884. Akitt, Thos., Parkhill, Bishopston, Renfrewshire, Chemist.
1883. Albright, G. S., Bromesberrow Place, Ledbury, Chemical Manufacturer.
- O.M. Albright, W. A., 29, Frederick Road, Edgbaston, Birmingham, Chemical Manufacturer.
1906. Alcock, Frank H., 9, Broad Street Corner, Birmingham, Analyst.
1907. Alcock, J. E., 51, Gill Street, Moston Lane, Blackley, Manchester, Chemist.
1902. Alden, Frederick W., 500, Madison Street, Waukesha, Wis., U.S.A., Chemist.
1898. Alden, John, Chemical Laboratory, Pacific Mills, Lawrence, Mass., U.S.A., Chemist.
1906. Alder, H. W., Hacienda Cartavio, Trujillo, Peru, Works Chemist.
1900. Aldrich, Roger C., c/o Franklin H. Kalbfleisch Co., Elizabeth, N.J., U.S.A., Mechanical Engineer.
1890. Aldrick, Edwin John, 53, Alpha Road, West Ferry Road, Millwall, E., Works Sub-Manager.
1899. Alexander, D. Basil W., 1020, Date Street, Los Angeles, Cal., U.S.A., Chemist.
1900. Alexander, Jerome, c/o National Gum and Mica Co., 502-510, West 45th Street, New York City, U.S.A., Chemist.
1883. Alexander, W. T., Crummock, Eccles, Manchester, Drysalter.
1906. Allan, David, c/o Price's Patent Candle Co., Ltd., Belmont Works, Battersea, S.W., Chemist.
1891. Allan, F. H., Tielke, Ellesmere, Robin Hood, near Wakefield, Analytical Chemist.
1898. Allan, John, 77, Northen Grove, West Didsbury, near Manchester, Chemist.
1907. Allard, M. L., c/o Gutta Percha and Rubber Manufacturing Co., O'Hara Avenue, Toronto, Canada, Chemist.
1902. Allbright, Wm. B., 5139, Lexington Avenue, Chicago, Ill., U.S.A., Chemical Engineer.
- O.M. Aldred, C. H., 8, St. Margaret's Road, Plumstead Common, Kent, Analytical Chemist.
1907. Allely, W. S., 3, Regent Street, Birmingham, Metal Merchant.
1903. Allen, Chas. A., 295, Blackburn Road, Darwen, Lancashire, Chemist.
1908. Allen, Geo. V., c/o British American Dyeing Co., Montreal, Canada, Manager.
- O.M. Allen, J., 164, Upper North Street, Poplar, E., Manufacturing Chemist.
1907. Allen, J. Fenwick, 147, Withington Road, Whalley Range, Manchester.
1889. Allen, R. L., Hillside, and (Journals) c/o Brunner, Mond and Co., Ltd., Sandbach, Cheshire, Analytical Chemist.
1908. Allen, Simeon C., 81, Lake Avenue, Rochester, N.Y., U.S.A., Consulting Chemist.
1900. Allen, Wilfrid T., Allington, Bexley, Kent, Director.
1904. Allen, Wm. R., c/o Watson, Jack and Co., Bell Telephone Building, Montreal, Canada, Chemical Manufacturer.
1893. Allerton, Rt. Hon. Lord, F.R.S. (Journals), Allerton Hall, near Leeds; and c/o W. L. Jackson and Sons, Ltd., Buslingthorpe, Leeds, Tanner.
- O.M. Allusen, A., Gateshead-on-Tyne, Chemical Manufacturer.
1886. Allibon, G. H., Mayfield, Balmoral, Belfast, Ireland, Chemical Works Manager.
1887. Alliot, J. B., Messrs. Manlove, Alliot, and Co., Ltd., Nottingham, Mechanical Engineer.
1895. Allison, Wm. O., 100, William Street, New York City, U.S.A., Publisher of "Oil, Paint and Drug Reporter."
1905. Allpass, Jas., c/o The Clayton Aniline Co., Ltd., Clayton, Manchester, Secretary.
1889. Alpiar, Agop, Smyrna, Asia Minor, Morphia Manufacturer.
1899. Alsop, Wm. K., Ridgway, Pa., U.S.A., Chemist.
1904. Alton, W. Lester, 11, Briar Walk, Putney, S.W., Chemist.
1905. Amory, L. H., c/o Messrs. J. Heathcoat and Co., Tiverton, Devon, Lace Manufacturer.
1900. Anderson, Jas. W., The Paddock, Lower Halling, near Rochester, Kent, Analytical Chemist.
1889. Anderson, Robt. T. R., 42, Roslea Drive, Dennistoun, Glasgow, Technical Chemist.
1894. Anderson, Dr. W. Carrick, 7, Scott Street, Garnet Hill, Glasgow, Consulting Chemist.

1905. Andrae, Dr. E. P., Crestalta, Champion Hill, London, S.E., Chemist.
1907. Andrews, Chas. T., Estação de Miguel Burnier, E.F.C.B., Minas Geraes, Brazil, Chemist.
1889. Andrews, Clement W., c/o The John Crerar Library, Wabash Avenue and Washington Street, Chicago, Ill., U.S.A., Librarian.
1904. Andrews, Geo. D., c/o J. & J. Colman, Ltd., Carrow Works, Norwich, Chemist.
1903. Andrews, Wm. H., 79, Tonawanda Street, Buffalo, N.Y., U.S.A., Manager (Varnish Works).
1903. Aniloff, N. A., St. Vincent's, Orsett Road, Grays, and (Journals) Central Wharf, Bow, E., Chemist.
- O.M. Angell, J., 6, Beaconsfield, Derby Road, Withington, Manchester, Chemical Lecturer.
1892. Annandale, C. J. R., 126, Earnsdale Road, Darwen, Lancs., Paper Maker.
1883. Annandale, Jas. H., Polton Paper Works, Midlothian, N.B., Paper Maker.
1894. Ansbacher, L. A., 253, Broadway, New York City, U.S.A., Colour Manufacturer.
1902. Anthony, John, 82, Bay Street, Toronto, Canada.
1899. Appleby, C. W., Farnworth, near Widnes, Lancashire, Pith and Size Manufacturer.
1904. Appleby, Jos., Farnley, Moor Lane, Great Crosby, Liverpool, Flour Miller.
1895. Appleby, Prof. W. R., 911, 5th Street S.E., Minneapolis, Minn., U.S.A., Professor of Mining and Metallurgy.
1907. Appleton, Francis H., jun., P.O. Box 815, Franklin, Mass., U.S.A., Rubber Manufacturer.
1894. Appleton, H. A., 63, Rosedale Road, Forest Gate, E., Analytical Chemist.
1900. Appleyard, Geo. H., 4, Ash Grove, Beverley Road, Hull, Chemist.
1905. Appleyard, Jas. R., Royal Technical Institute, Salford, Lecturer.
- O.M. Archbutt, Leonard, The Yews, Madeley Street, Derby, Analytical Chemist.
1899. Archdale, T. Henry, 77, Queen's Road, Blackburn, Manager of Tar and Ammonia Works.
1904. Archdale, Wm., 21, Oldham Road, Miles Platting, Manchester, Manager of Chemical Works.
1901. Ardagh, Edw. G. R., Faculty of Applied Science, University of Toronto, Canada, Chemist.
1900. Arden, Edw., Greengates, Davyhulme, Urnston, Manchester, Chemist.
1907. Armstrong, Chas. F., Champarun Sugar Factory, Barrah Chakiah P.O., Tirhoot State Railway, India, Technical Chemist.
1902. Armstrong, Edward E., Pennsylvania Salt Manufacturing Co., Natrona, Pa., U.S.A., Manufacturing Chemist.
1905. Armstrong, Dr. E., Frankland, 98, London Road, Reading, Works Chemist.
1899. Armstrong, Richard, Saul Street Soap Works, Preston, Lancashire, Soap Manufacturer.
1905. Armstrong, Theodore, 115, Chestnut Street, Philadelphia, Pa., U.S.A., President, Penn. Salt Manufacturing Co.
1905. Arnold, Frank L., 32, School Street, North Woburn, Mass., U.S.A., Chemist.
1901. Arnold, G. Edmund, 6, Kingsfield Terrace, Faversham, Kent, Manager (Cotton Powder Co., Ltd.).
1899. Arnott, Dr. G. W. Campbell, c/o Fertiliser Manufacturers' Association, 79, Mark Lane, London, E.C., Agricultural Chemist.
1903. Arnott, J. S., Moros, 42, 2^a, Gijon, Spain, Chemist and Metallurgist.
1901. Arndel, Arthur S. D., 43, Pixmore Avenue, Letchworth, Herts, Chemical Engineer.
1901. Asano, K., 25, Kitachonyachō, Kyobashi, Tokyo, Japan, Mining Chemist.
1906. Ash, Chas. S., 180, Townsend Street, San Francisco, Cal., U.S.A., Chemist.
1908. Ashbury, J. W., c/o John Brown and Co., Ltd., Laboratory, Atlas Works, Sheffield, Chief Chemist.
1903. Ashley, Frank R., P.O. Box 1605, Denver, Colo., U.S.A., Manufacturing Chemist.
1900. Ashton, Jas., Rhodes Farm, Whitefield, Manchester, Chemist and Manager.
1890. Ashton-Bost, W. D., *See* Bost, W. D. Ashton.
1885. Ashwell, J. H., 117, Waterloo Crescent, The Forest, Nottingham, Bleacher and Dyer.
1894. Ashworth, Arthur, Feinhill Chemical Works, Bury, Lancs., Chemical Manufacturer.
1908. Ashworth, D. Irving, P.O. Box 38, Wappingers Falls, N.Y., U.S.A., Chemist.
1908. Asmus, Grover E., 4011, Hindson Boulevard, West Hoboken, N.J., U.S.A., Chemist.
1907. Aspey, Urban, jun., New Station Soap Works, School Close, and (Journals) 11, Neville Street, Leeds, Works Manager and Chemist.
1898. Aspinall, Thos., 62, Gilnow Road, Bolton, Analytical and Manufacturing Chemist.
1900. Aston, Bernard C., Agricultural Department, Wellington, New Zealand, Chemist.
1891. Atkins, C. E., Teigngrace, Bycullah Park, Enfield, N., Chronometer Maker.
1885. Atkinson, A. J., 44, Stuart Street, Cardiff, Analytical Chemist.
1900. Atkinson, Jno. W., Betteravia, Cal., U.S.A., Chemist.
1905. Atteaux, F. E., 176, Purchase Street, Boston, Mass., U.S.A., Dyestuff Importer.
- O.M. Attfield, Dr. J., F.R.S., Ashlands, Watford, Herts.
1900. Atwood, Frank W., 216, Milk Street, Boston, Mass., U.S.A., Chemist.
1895. Auchterlonie, Wm., c/o Clark Thread Co., Newark, N.J., U.S.A., Dyeworks Manager.
1907. Auchu, Henry, Emporium, Pa., U.S.A., Explosives Manufacturer.
1901. Auden, Dr. H. A., Westwood, Grassendale, Liverpool, Chemist.
1897. Auger, Chas. L., 425, Park Avenue, Paterson, N.J., U.S.A., Silk Dyer.
1902. Austin, J. H., Allscott, Wellington, Shropshire, Analytical Chemist.
1901. Auty, Albert M., c/o John Smith and Sons, Ltd., Field Head Mills, Bradford, Works Chemist.
1902. Avery, D., Working Men's College, Melbourne, Vic., Australia, Teacher of Chemistry.
1890. Aykroyd, H. E., Scatcliffe, Queen's Road, Ilkley, Yorks, Dyer.
1899. Aylsworth, Jonas W., 223, Midland Avenue, East Orange, N.J., U.S.A., Chemist.

B

1904. Babb, Edward E., 41, Central Wharf, Boston, Mass., U.S.A., Food Analyst.
1908. Babington, Fred. W., Customs Lab., Customs Dept., Ottawa, Canada, Analyst.
1895. Bacon, Nathaniel T., Peace Dale, Rhode Island, U.S.A., Chemical Engineer.
1897. Bacon, Wm., 4, New Court, Lincoln's Inn, W.C., Chemist.
1897. Badock, Stanley H., Holmwood, Westbury on Trym, near Bristol, Smelter.
1898. Baekeland, Dr. Leo, Snug Rock, North Broadway, Yonkers, N.Y., U.S.A., Manufacturing Chemist.
1902. Baer, Dr. Samuel H., 212, South 7th Street, St. Louis, Mo., U.S.A., Consulting Chemist.
1903. Bailey, Prof. E. H. S., The Library, Kansas State University, Lawrence, Kas., U.S.A., Professor of Chemistry.
1885. Bailey, Edwin M., Almond Hill, Pumphreston, Mid Calder, N.B., Technical Chemist.
1908. Bailey, F. W., Overstone, Robertson Road, Buxton.
1883. Bailey, Dr. G. H., Marple Cottage, Marple, Cheshire, Chemical Lecturer.
1903. Bailey, Harold J., Maritime Coke Works, Pontypriidd, S. Wales, Chemist.
1906. Bailey, Ralph W., 66, Cherry Street, Elizabeth, N.J., U.S.A., Chemist.
1888. Bailey, Dr. T. Lewis, 13, St. Alban's Road, Swansea, H.M. Inspector of Alkali Works.
1888. Bailey, Walter P., Empresa de Gas, 13, San Roque, Seville, Spain, Chemical Engineer and Manager.
1902. Bain, Prof. Jas. Watson, Faculty of Applied Science, The University, Toronto, Ont., Canada, Chemist.

1890. Baird, H. Harper, 14, Cross Street, Hatton Garden, London, E.C., Laboratory Furnisher.
1902. Baird, Dr. Julian W., Massachusetts College of Pharmacy, Boston, Mass., U.S.A., Professor of Chemistry.
1908. Baird, M. M., 18, Jedburgh Avenue, Rutherglen, Glasgow, Analytical Chemist.
1891. Baird, Wm., c/o Lewis Berger and Sons, Ltd., Homerton, N.E., Technical Chemist.
1895. Baird, W. Raymond, 271, Broadway, New York City, U.S.A., Patent Lawyer.
1890. Bairstow, John, Burley, Queen's Park, Chester, Chemical Works Manager.
1903. Baker, Arthur, 2, Carlton Avenue, Horns Cross, Greenhithe, Kent, Chemist.
1902. Baker, Chas. F., Technical College, Sunderland, Lecturer in Chemistry.
1901. Baker, F. Guy Stirling, Marryatt's Lodge, The Forest, Snaresbrook, Essex, Student.
1883. Baker, Harry, Epworth House, Moughland Lane, Runcorn, Analytical Chemist.
1899. Baker, H. Fenimore, c/o Thomsen Chemical Co., Baltimore, Md., U.S.A., President.
1904. Baker, John T., c/o J. T. Baker Chemical Co., Phillipsburg, N.J., U.S.A., Manufacturing Chemist.
1892. Baker, Julian L., Stainesbury Holt, Kingston Road, Staines, Brewing and Sugar Chemist.
1886. Baker, Theodore, Fabr. Nacional de Polyoro Piquete, Est. de Sao Paulo, Brazil, Analytical Chemist.
1898. Baldwin, Abram T., Solvay Process Co., Syracuse, N.Y., U.S.A., Alkali Manufacturer.
1903. Baldwin, F. H., Bergenport Chemical Works, Bayonne, N.J., U.S.A., Superintendent.
1903. Baldwin, Dr. H. B., 927, Broad Street, Newark, N.J., U.S.A., Chemist (Dept. of Public Health).
1903. Ball, S. F., Hull Avenue and 209th Street, New York City, U.S.A., Analytical Chemist.
1889. Ballantyne, Horatio, 75, Chancery Lane, London, W.C., Analytical and Consulting Chemist.
1903. Ballantyne, W. H., 111, Hatton Garden, London, E.C., Patent Agent's Assistant.
- O.M. Ballard, Edw. G., Greenfield Cottage, Hoole Village, Chester, Alkali Works Inspector.
1891. Ballinger, Jno., Free Library, Cardiff, Librarian.
- O.M. Bamber, H. K., 9, Victoria Street, London, S.W., Consulting Chemist.
1894. Bamber, H. K. G., Ingress House, Greenhithe, Kent, Cement Works Chemist and Manager.
1898. Bamford, Harry, 70, Duckworth Terrace, Bradford, Yorks, Dyer.
1905. Bampton, Geo. F., 39, Oliver Street, Boston, Mass., U.S.A., Chemist.
1906. Bancroft, John, Wilmington, Del., U.S.A., Bleacher and Dyer.
- O.M. Banister, H. C., Elmhurst, Blundellsands, near Liverpool, Chemical Works Manager.
1890. Banks, Jno. H., c/o Ricketts and Banks, 104, John Street, New York City, U.S.A., Mining Engineer.
1895. Bannan, John F., 59, Court Street, North Andover, Mass., U.S.A., Chemist (Woollen Mill).
- O.M. Bannister, R., 59, Tregunter Road, South Kensington, S.W., Analytical Chemist.
- O.M. Bannister, W., Burvale, Watford, Herts, Manufacturing Chemist.
1908. Barber, Percy S., Premier Portland Cement Co., Ltd., Irthlingborough, Wellingborough, Chemist.
1901. Barber, Capt. René R., Georgetown, Ont., Canada, Analytical Chemist.
1892. Barden, Alf., Far Bank, Shelley, near Huddersfield, Glue and Size Maker.
1907. Bardorf, C. F., c/o St. Lawrence Sugar Refining Co., Maisonneuve, P.Q., Canada, Chief Chemist.
1895. Bardwell, Fred L., Massachusetts Institute of Technology, Boston, Mass., U.S.A., Assistant Professor of Chemistry.
1902. Barker, Hugh S., 32, Cumberland Avenue, Sefton Park, Liverpool, Laboratory Furnisher.
1895. Barlow, Clinton W., 103-105, Greene Street, New York City, U.S.A., Merchant.
1908. Barlow, Lt.-Col. Sir Hilary W. W. Bart., R.A., 84, Shooter's Hill Road, Blackheath, S.E., Superintendent (Royal Laboratory, Woolwich).
1901. Barlow, John J., 177, Manchester Road, Acerington, Calico Printer's Chemist.
1899. Barlow, Wm., 2, Delamere Street, Higher Openshaw, Manchester, Analytical Chemist.
1906. Barnes, A. G., Grassmoor Collieries, Chesterfield, Colliery Proprietor.
1891. Barnes, Edward A., Sandalen, Aasenijorden, Norway, Technical Chemist.
1901. Barnes, Fred., 1, Richmond Villa, London Road, Milton Regis, Sittingbourne, Kent, Paper Mill Chemist.
1905. Barnes, F. V., 44, Lucknow Avenue, Nottingham, Gas Works Chemist.
1884. Barnes, H. J., Phoenix Chemical Works, Hackney Wick, N.E., Manufacturing Chemist.
1884. Barnes, Jonathan, 301, Great Clowes Street, Manchester, Analytical Chemist.
- O.M. Barnes, Jos., Green Vale, Westhoughton, near Bolton, Lancashire, Analytical Chemist.
1902. Barnett, Marcus S., Colonial Sugar Refining Co., Ltd., O'Connell Street, Sydney, N.S.W., Australia, Sugar Works Chemist.
1897. Barnett, Robt. E., 9, Virginia Road, Leeds, Headmaster (Leeds Technical School).
1901. Baron, Wm. Briscoe, c/o The Fuel Saving and Water Treating Co., Ltd., 2, Booth Street, Albert Square, Manchester, Chemist.
- O.M. Barr, J., Dinting Vale, Dinting, near Manchester, Chemical Manager.
1905. Barraclough, C. E., 2, Wood View Terrace, Manningham, Bradford, Chemist.
1890. Barraclough, Wm. H., Beechwood, Mortomley, near Sheffield, Analytical Chemist.
1896. Barratt, J. Treeby, Bronheulog, Mostyn, North Wales, Chemist and Manager.
1890. Barrett, Arthur A., 30, Endwell Street, Brockley, S.E., Manufacturer of Essential Oils.
1907. Barrett, John H., 215, Carlton Street, Toronto, Canada, Superintendent.
1907. Barrett, Maurice, The Leeds Fireclay Co., Ltd., Burmantofts Works, Leeds.
1890. Barrie, D. McLaurin, P.O. Box 193, Germiston, Transvaal, Metallurgist.
1900. Barrow, Jos., 13, The Grove, Beblington, Cheshire, Chemist.
1906. Barrs, Chas. E., 20, Carlingford Road, Hampstead, N.W., Analyst.
1905. Barry, Eugene, Ayer, Mass., U.S.A., Leather Manufacturer.
1893. Barton, G. E., c/o Whitall, Tatum, and Co., Flint Glass Works, Millville, N.J., U.S.A., Technical Chemist.
1903. Bartripp, Geo. F., 20, Grove Road, Wanstead, Essex, Analytical Chemist.
1905. Baruch, Edgar, 945, South Olive Street, Los Angeles, Cal., U.S.A., Chemical Engineer.
1895. Baskerville, Dr. Chas., College of the City of New York, New York, U.S.A., Professor of Chemistry.
1884. Bassett, H., 26, Belitha Villas, Barnsbury, N.
1908. Bassett, Henry, jun., Chemical Department, University of Liverpool, Assistant Lecturer.
1899. Bassett, Wm. H., 146, Litchfield Street, Torrington, Conn., U.S.A., Chemist.
1890. Bate, William, Upton Villa, Hayle, Cornwall, Technical Chemist (National Explosives Co., Ltd.).
1903. Bateman, A. H., 34, Bridge Avenue, Hammersmith, W., Chemist.
1885. Batty, R. B., Wharncliffe, Erdington, near Birmingham, Nickel Works Manager.
1903. Baty, E. J., 130, Edmund Street, Birmingham, Chemist.
1903. Bauer, Geo. W., 632, Sacramento Street, San Francisco, Cal., U.S.A., Vice-President and Chemist (Hop and Malt Co.).
1900. Baur, Jacob, 67, Wells Street, Chicago, Ill., U.S.A., Liquid Carbonic Acid Manufacturer.
1898. Baxter, John G., Riverview, Burch Road, Rosherville, Gravesend, Kent, Chemist.

- O.M. Baxter, W. H., Nuthurst, High Road, Streatham, S.W., Brewery Director.
1899. Bayly, Francis W., Church Cobham, Surrey, Assayer.
1904. Bayly, Harold G., Moatside, Bedford, Analytical Chemist.
1908. Bayly, Percival G. W., Mines Dept. Lab., Spring Street, Melbourne, Victoria, Government Metallurgical Chemist.
1897. Beadle, Alec A., Wenden, Dawlish, South Devon, Electro-Chemist.
1886. Beadle, Clayton, Halewood, Sidcup, Kent, Consulting Chemist.
1909. Beal, J. H., Scio, Ohio, U.S.A., Professor of Pharmacy.
1908. Bealey, Herbert C., c/o A. C. Bealey and Son, Radcliffe, near Manchester, Bleacher and Chemical Manufacturer.
- O.M. Beanes, E., Moatlands, Paddock Wood, Kent, Manufacturing Chemist.
1908. Beardmore, Walter W., Acton West, Ont., Canada, Leather Tanner.
1907. Beardsley, Dr. Alling P., 165, Minerva Street, Derby, Conn., U.S.A., Chemist (New Haven Gas Co.).
1908. Beasley, Fred. G., 44, Green Street, Smethwick, near Birmingham, Metallurgical Chemist.
1905. Beasley, Jno. K., c/o The Broomassie Mines, Ltd., Broomassie, Gold Coast Colony, W. Africa, *via* Lekondi, Metallurgical Chemist.
1883. Beaven, E. S., 5, Boreham Terrace, Warminster, Wilts, Maltster.
1897. Beaver, Chas. J., Holme Lea, Ashley Road, Hale, Cheshire, Chemist.
1905. Beckers, Dr. Wm., 117, Hudson Street, New York City, U.S.A., Chemist.
- O.M. Beckett, G. H., Hartford, 35, South Beach Avenue, Ardrossan, Scotland, Analytical Chemist.
1898. Beckett, Jos. H., 41, Serpentine Road, Egremont, Cheshire, Analytical Chemist.
1899. Bedford, Alf. C., 26, Broadway, New York City, U.S.A., Chemical Merchant.
1891. Bedford, Chas. S., Rocella, Weetwood, Headingley, Leeds, Manufacturing Chemist.
1891. Bedford, Jas. E., Messrs. Wood and Bedford, Airedale Chemical Works, Leeds, Manufacturing Chemist.
- O.M. Bedson, Prof. P. Phillips, Armstrong College, Newcastle-on-Tyne, Professor of Chemistry.
1901. Beevers, Clifford J., c/o Brotherton and Co., Ltd., Holmes Street, Dewsbury Road, Leeds; and (Jnls.) 12, Parish Ghyll Road, Ilkley, Yorks, Analyst.
1899. Behr, Dr. Arno, 432, Arlington Court, Pasadena, Cal., U.S.A., Chemist.
1903. Behrend, F., 54, Front Street, New York City, U.S.A., Importer of Chemical Stoneware.
- O.M. Beilby, Dr. George T., F.R.S., 11, University Gardens, Glasgow, Chemical Engineer.
1906. Belden, A. W., Fuel Testing Plant, U.S. Geological Survey, Denver, Colo., U.S.A., Coke Expert.
1906. Bell, H. N., Tay Street, Invercargill, New Zealand, Company Manager.
1884. Bell, Sir Hugh, Bart., Middlesbrough-on-Tees, Soda and Iron Manufacturer.
1900. Bell, Hugh P., 17, Tothill Street, Westminster, S.W., Chemist.
- O.M. Bell, J. Carter, Bank House, The Cliff, Higher Bronghton, Manchester, Public Analyst.
1886. Bell, J. Ferguson, Derby Gas Light and Coke Co., Derby, Gas Engineer.
1907. Bell, Marcus, Explosives Dept., 423, Flinders Lane, Melbourne, Victoria, Chemist.
1905. Bell, Miss M. M., Tulane University Library, New Orleans, La., U.S.A., Librarian.
1903. Bell, P. Carter, Millburn, N.J., U.S.A., Chemical Manufacturer.
1902. Bement, Alberto, 2114, Fisher Building, Chicago, Ill., U.S.A., Consulting Mining Engineer.
- O.M. Bendix, D., 371, Romford Road, Forest Gate, E., Managing Chemist, British Alizarin Co., Ltd.
1897. Benfey, Dr. Hans, 65, Birchfields Road, Rusholme, Manchester, Manufacturing Chemist.
1907. Bengough, Guy D., The University, Liverpool, Lecturer on Metallurgy.
1903. Benham, Keith, Deans Hill, Stafford, Analytical and Consulting Chemist.
1902. Benjamin, Albert, Springbrook Works, Middleton Road, Oldham, Bleach and Dyeworks Manager.
- O.M. Benjamin, Dr. M., Smithsonian Institution, Washington, D.C., U.S.A., Consulting Chemist.
1908. Benkert, Arthur L., c/o Cassella Color Co., 182, Front Street, New York City, U.S.A., Chemist and Salesman.
1904. Benn, R. H. D., 16, Springfield Avenue, Westmount, Montreal, Canada, Analytical Chemist.
1899. Bennett, Alex. H., c/o G. H. Ogston & Moore, Catania, Sicily, Chemist.
1901. Bennett, Arnold, c/o Montreal Steel Works, Ltd., St. Patrick Street, Montreal, Canada, Chemist.
1907. Bennett, H. Garner, Leather Industries Dept., The University, Leeds, Leather Chemist.
1902. Bennie, P. McN., P.O. Box 29, Niagara Falls, N.Y., U.S.A., Consulting Chemist.
1909. Benson, George F., Edwardsburg Starch Co., 164, St. James Street, Montreal, Canada, President and Managing Director.
1906. Benson, Richard W., c/o Geo. Craddock & Co., Wakefield, Yorks, Analytical Chemist.
1905. Bentley, Prof. W. B., 42, Morris Avenue, Athens, Ohio, U.S.A., Professor of Chemistry.
1901. Bentley, Wm. H., 12, Cromwell Terrace, Irlam, near Manchester, Technical Chemist.
1890. Bentz, Ernest, 107, Shaw Lane, Dinting, near Manchester, Lecturer on Dyeing.
1905. Berge, Henry vom, c/o Schoellkopf & Co., Perry and Mississippi Streets, Buffalo, N.Y., U.S.A., Manager.
1884. Beringer, J. J., Basset Road, Camborne, Cornwall, Metallurgist.
1893. Berk, Fred. W., 1, Fenchurch Avenue, London, E.C., Chemical Manufacturer.
1907. Berk, Paul F., 1, Fenchurch Avenue, London, E.C.,
1908. Berlinerblau, Dr. Joseph, 8, Szpitalna Street, Warsaw, Russian Poland, Industrial Chemist.
1900. Bermingham, Jno., jun., Room 317, Union Trust Building, San Francisco, Cal., U.S.A., Superintendent.
1889. Bernard, Jas., jun., Ranipet, North Arcot, Madras Presidency, India; and (Jnls.) c/o Chas. Hadfield, Viaduct House, Dinting, near Manchester, Chemical Works Manager.
1897. Berry, Albert E., Ontario, Snarebrook, Essex, Works Manager.
1906. Berry, Arthur J., 5, University Gardens, Glasgow, Student of Chemistry.
1883. Berry, E. E., Bordighera, Italy, and (Journals) c/o C. H. Grinling, 17, Rectory Place, Woolwich, S.E., Technical Chemist.
1889. Berry, G. F., 9, Musgrove Road, Jerningham Road, New Cross, S.E., Chemical Works Manager.
1903. Berry, W. G., 329, West 83rd Street, New York City, U.S.A., Chemist.
1909. Beskow, K. J., Skanska Superfosfat och Svofvelsyre Fabriks A.B., Helsingborg, Sweden, Head Engineer.
1886. Best, Dr. T. T., Hardshaw Brook Chemical Works, St. Helens, Lancashire, Technical Chemist.
1907. Bettermann, Heinrich, Doemitz-on-Elbe, Germany, Explosives Works Manager.
1901. Betts, Anson G., Troy, N.Y., U.S.A., Chemist.
- O.M. Bevan, E. J., 4, New Court, Lincoln's Inn, London, W.C., Public Analyst and Consulting Chemist.
1900. Bevan, Jno. W., Risedale, St. James' Crescent, Swansea, Manager of Metallurgical Works.
- O.M. Beveridge, Jas., c/o Miramichi Pulp and Paper Co., Ltd., Chatham, N.B., Canada, Pulp and Paper Manufacturer.
1909. Bewick, R. M., c/o United Alkali Co., Ltd., 30, James Street, Liverpool, Traveller.
1898. Bhattacharyya, Haripada, Gun and Shell Factory, Ishapore, Bengal, India, Chemist.

1902. Biach, Dr. Ludwig K., 223, Central Avenue, Norwich, Conn., U.S.A., Chemist and Colorist.
1907. Bianchi, Harold, c/o L. M. Booth Co., 136, Liberty Street, New York City, U.S.A., Analytical Chemist.
1896. Bibby, John, c/o J. Bibby & Sons, Formby Street, Liverpool, Chemist.
- O.M. Bickerdike, W. E., Bryer's Croft, Wiltshire, near Blackburn, Manufacturing Chemist.
1907. Bickerstaffe, Robt., c/o Thomas and Green, Ltd., Soho Mills, Woodburn Green, S.O., Bucks., Chemist.
1901. Bielecki, Dr. Jan, 66, Krakowski Przedmieście, Warsaw, Poland, Chemist.
1908. Bierbaum, E. C., Monona, Iowa, U.S.A., Assayer.
1903. Bierwirth, L. W., P.O. Box 863, Rio de Janeiro, Brazil, Civil Engineer.
1884. Biggart, J. Wm., 29, Cathcart Street, Greenock, N.B., Analytical Chemist.
1891. Biggart, Wm. L., Rossarden, Kilmalcolm, N.B., Public Analyst.
- O.M. Biggs, B., 110, Cannon Street, London, E.C., Chemical Merchant.
- O.M. Billing, H. S., 42, Kingsley Road, Mutley, Plymouth, Analytical and Managing Chemist.
1896. Billings, Edgar F., 178, Freeport Street, Dorchester, Mass., U.S.A., Manufacturing Chemist.
1896. Billington, Chas., jun., Heimath, Porthill, Longport, Staffordshire, Metallurgist.
1903. Binns, John H., Thornfield, Mystic Pond, Methuen, Mass., U.S.A., Dyer and Finisher.
1896. Bird, Arthur W., c/o S. Berger & Co., Bromley-by-Bow, E., Works Engineer.
1907. Bird, Charles S., jun., East Walpole, Mass., U.S.A., Paper Maker.
1896. Bird, Jno. B., Minver House, 61, Bateman Street, Cambridge, Manure Manufacturer.
1907. Bird, Dr. R. M., University of Virginia, Charlottesville, Va., U.S.A., Professor of Chemistry.
1895. Bird, Wm. R., (communications) 125, Goddard Avenue; (Journals) Laboratory, G.W.R. Works, Swindon, Wilts, Analytical Chemist.
1902. Bird, W. Robt., 217, Newport Road, Cardiff, Oil Merchant.
1885. Birley, R. K., c/o Chas. Macintosh and Co., Ltd., Cambridge Street, Manchester, India-rubber Manufacturer.
1883. Bishop, A. Conway, Three Mills Lane, Bromley-by-Bow, E., Manufacturing Chemist.
1884. Bishop, Fred, c/o Burmah Oil Co., P.O. Box 67, Rangoon, Burmah, Technical Chemist.
1903. Bishop, Howard B., 609, Greene Avenue, Brooklyn, N.Y., U.S.A., Chemist.
1903. Bishop, J. T. F., Chemical Club, Victoria Hotel, Manchester, Secretary.
1905. Bixby, Willard G., 194, Hester Street, New York City, U.S.A., Blacking Manufacturer.
1905. Bjerregaard, August P., Box 322, Las Cruces, New Mexico, U.S.A., Farmer.
1904. Black, J. Wyclif, 20, Mardale Crescent, Edinburgh, Analytical Chemist.
1902. Black, W. Geoffrey, St. John's House, Christchurch Road, Norwich, Chemist.
1908. Blackhall, Bertram, 48, Frontenac Street, Kingston, Ontario, Canada, Manufacturing Chemist.
1894. Blackmore, H. S., 612 F. Street, N.W., Washington, D.C., U.S.A., Industrial Chemist.
1896. Blagden, Victor, 50-51, Lime Street, London, E.C., Chemical Merchant.
1883. Blagden, W. G., The Manor House, Harting, near Petersfield, Chemical Merchant.
1897. Blair, Andrew A., 406, Locust Street, Philadelphia, Pa., U.S.A., Analytical Chemist.
1884. Blake, Jas., Thames Sugar Refinery, Silvertown, E., Manager.
1890. Blakey, A. J., Dudbridge Mills, Stroud, Gloucestershire, Dyer.
1893. Blears, John, c/o Langworthy Bros. and Co., Ltd., Greengate Mills, Salford, Dyer and Calico Printer.
- O.M. Bles, A. J. S., 32, Chorlton Street, Manchester, Chemical Merchant.
1908. Blichfeldt, S. H., Cross Deep, Osterley Park Road, Southall, Middlesex, Bacteriologist and Fermentation Chemist.
1905. Bliss, H. J. W., c/o The Thames Varnish Co., Island Wharf, Rainham, Essex, Chemist.
1889. Bloeder, Victor G., Station D., Baltimore, Md., U.S.A., Manufacturing Chemist.
1908. Blomeley, Adam Y., Canada Sugar Refinery, Ltd., Montreal, Canada, Chemist.
1891. Bloomer, Fred. J., Penpont, Clydach, R.S.O., Glamorgan, Nickel Works Manager.
1886. Blount, Bertram, Laboratory, 76 and 78, York Street, Westminster, S.W., Analytical Chemist.
1888. Bloxam, A. G., 105, Birkbeck Bank Chambers, Holborn, W.C., Chemist and Patent Agent.
1890. Bloxam, W., Popplewell, Clothworkers Research Laboratory, The University, Leeds, Research Chemist.
1903. Blumenthal, Lionel, The Lindens, Stanley Road, Broughton Park, Manchester, Chemist.
1886. Blundstone, E. R., 77, York Street, Westminster, S.W., and (Journals) Heathfield, Park Road, Hampton Hill, Middlesex, Consulting Chemist.
1908. Blyth, Jas. R., c/o Penketh Tannery Co., Penketh, near Warrington, Leather Trades Chemist.
1906. Blyth, M. Wynter, The Lodge, Ardsley, near Barnsley, Yorks, Analytical and Consulting Chemist.
1905. Blyth, Thomas R., Uphall Chemical Works, Ilford, Essex, Analytical Chemist.
1908. Blythe, Fred. C., Holland Bank, Church, Lancashire, Chemical Manufacturer.
- O.M. Boake, A., Warton Road, Stratford, E., Manufacturing Chemist.
1888. Boake, Edmund J., Aberffraw, Nursery Road, Loughton, Essex, Manufacturing Chemist.
1899. Boehm, Fred., 16, Jewry Street, London, E.C., Chemical Agent and Merchant.
1898. Bogert, Prof. Marston T., Department of Organic Chemistry, Columbia University, New York City, U.S.A., Instructor in Organic Chemistry.
1903. Boissevain, Chas. E. H., 92, van Eeghenstraat, Amsterdam, Holland, Chemical Manufacturer.
1903. Bolam, Dr. H. W., 2, Summerfield, Leith, N.B., Lecturer on Chemistry.
1907. Boley, Walter, Uerdingen am Rheiu, Germany, Manufacturing Chemist.
1901. Bolton, E. Richards, 16, Flanchford Road, Ravenscourt Park, W., Manufacturing Chemist.
1905. Bond, John, Crowlands, Southport, Engineer.
1905. Bond, Josiah, Patagonia, Arizona, U.S.A., Mining Engineer.
1905. Bone, Dr. W. A., F.R.S., West House, Lidgett Park Road, Roundhay, Leeds, Lecturer in Chemistry and Metallurgy.
1892. Bookman, Dr. S., 9, East 62nd Street, New York City, U.S.A., Chemist.
1888. Boor, Leonard G., 21, Mincing Lane, London, E.C., Chemical Merchant.
1896. Boot, John C., Engineer's Office, Delft, Holland, Chemist.
1908. Booth, Jos. W., Atlantic Mills, Providence, R.I., U.S.A., Superintendent.
1904. Booth, N. Parr, Laboratory, Cadbury Bros., Ltd., Bournville, near Birmingham, Chemist.
1894. Booth, Robt., 110, Cannon Street, London, E.C., Engineer.
1891. Boothby, Chas., Box 1127, G.P.O., Sydney, N.S.W., Chemist.
1903. Boral, Robin, Rhodes Mount, Rhodes, near Manchester, Works Manager.
1897. Borland, C. R., P.O. Box 683, Concord, Mass., U.S.A., Smokeless Powder Manufacturer.
- O.M. Borland, W. D., Beacon Lodge, Bean, via Dartford, Kent, Manufacturer of Explosives.
1906. Bornett, S., Andreaskloster 12, Köln, Germany, Technical Chemist.
1903. Boroschek, Dr. L., 24, West 82nd Street, New York City, U.S.A., Chemist.
1908. Bose, R., 92/5, Upper Circular Road, Calcutta, India, Chemical Works Manager.

1903. Bossi, Dr. Arnold L., Arnold Print Works, North Adams, Mass., U.S.A., Assistant Manager.
1890. Bost, W. D. Ashton, Cartvale Chemical Works, Paisley, N.B., Chemical Manufacturer.
- O.M. Bothamley, C. H., Weston-super-Mare, Somerset, County Director of Technical Instruction.
1890. Bott, Dr. W. Norman. *See* Norman-Bott, Dr. W.
1884. Böttger, Dr. H. T., Elberfeld, Germany; and (subs.) c/o The Bayer Co., Ltd., 19, St. Dunstan's Hill, E.C., Colour Manufacturer.
1901. Bottomley, Dr. J. Frank, c/o The Thermal Syndicate, Ltd., Neptune Road, Wallsend-on-Tyne, Consulting Chemist.
1906. Bottomley, W., c/o The United Alkali Co., Ltd., Fleetwood Salt Works, Fleetwood, Engineer.
- O.M. Boulton, H. E., 64, Cannon Street, London, E.C., Chemical Manufacturer.
- O.M. Boulton, Sir Samuel B., Bart., 64, Cannon Street, London, E.C., Chemical Manufacturer.
1883. Boulton, T. S., 14, Freegrove Road, Caledonian Road, N., Manager.
1905. Bourne, Lyman M., 820, Nostrand Avenue, Brooklyn, N.Y., U.S.A., Chemist.
1906. Boutwell, Arthur T., c/o Smith & Dove Manufacturing Co., Andover, Mass., U.S.A., Bleacher and Dyer.
1904. Bowden, Thos., 87, Todmorden Road, Littleborough, Lancs., Dyer and Chemist.
1905. Bowen, Henry, 28, Norwood Avenue, Buffalo, N.Y., U.S.A., Secretary.
1906. Bowen, Ralph A., c/o National Aniline & Chemical Co., 36, Purchase Street, Boston, Mass., U.S.A.
1885. Bowen, S. B., Brickfield Chemical Works, Llanelli, South Wales, Chemical Manufacturer.
1888. Bower, Frank, Brewery House, Spitalfields, E., Analytical Chemist.
1897. Bower, Wm. H., 29th Street and Gray's Ferry Road, Philadelphia, Pa., U.S.A., Chemical Manufacturer.
1906. Bowers, H. L., Port Hope, Ontario, Canada, Chemist and Metallurgist.
1892. Bowes, Harry, Staveley, Broomfield Road, Heaton Moor, Stockport, Analytical Chemist.
1889. Bowing, Juo., Church Walk, Wandsworth, S.W., Consulting Chemist.
1883. Bowley, Jos. John, Wellington Works, Battersea Bridge, and (Journals) 64, Redcliffe Gardens, London, S.W., Chemical Manufacturer.
1899. Bowley, J. Plunkett, 63, Beaufort Mansions, Chelsea, London, S.W., Varnish Manufacturer.
1883. Bowman, Dr. F. H., 4, Albert Square, Manchester, Chemical Manufacturer.
1908. Bowman, Fred. C., c/o Nichols Chemical Co., Tweed, Ont., Canada, Chemist.
1894. Bowman, Jas. H., 509, Ontario Street, London, Ont., Canada, Chemist.
1884. Bowman, R., c/o Bowman's Ltd., Lytchgoe's Lane, Warrington, Chemical Manufacturer.
1907. Bowman, Richard S., The Cerebos Works, Greatham, *via* Stockton-on-Tees, Chemist.
1896. Bowman, Walker, 39, Cortlandt Street, New York City, U.S.A., Chemist.
1904. Boyce, Framroze H., near Fire Brigade Station, Fort, Bombay, India, Technical Chemist.
1893. Boyce, Frank, c/o Goodall, Backhouse, and Co., White Horse Street, Leeds, Technical Chemist.
- O.M. Boyd, W., Mine Office, Frankfort, Pilgrim's Rest, Transvaal, Technical Chemist.
1899. Boyes, Herb. J., c/o Boyes & Kirk, Fabrica de Tecidos, Belemzinho, Sao Paulo, Brazil, Chemist.
1905. Brabrook, G. Hale, Box 333, Taunton, Mass., U.S.A., Manufacturer.
1906. Bracegirdle, Harold W., 13, Alan Road, Withington, Manchester, Chemist.
1885. Bradburn, J. A., 311, Montgomery Street, Syracuse, N.Y., U.S.A., Manufacturing Chemist.
1902. Bradbury, S., Ferncliffe, Milton Grove, Glebelands Road, Ashton-on-Mersey, Chemist.
1895. Bradford, Henry, Pampas Cottage, Goodwood, Chichester, Analytical Chemist.
1896. Bragg, Everett B., 1838, Chicago Avenue, Evanston, Ill., U.S.A., Manufacturing Chemist.
1891. Braithwaite, Isaac, Holly Croft, Kendal, Westmoreland, Drysalter.
1897. Braithwaite, Jno. O., Holme Lacey, Warren Road, Chingford, Essex, Pharmaceutical Research Chemist.
1903. Brance, J. S. S., 67, Coleraine Road, Blackheath, S.E., Demonstrator in Chemistry.
- O.M. Brannham, W., Bank Chambers, 300, Mare Street, Hackney, N.E., Chemical Engineer.
- O.M. Bramwell, G. H., Cowley Hill, St. Helens, Lancashire, Alkali Manufacturer.
1904. Brandeis, R., Oesterreichischer Verein f. Chem. und Metall. Produkte, Aussig, Austria, Chemical Manufacturer.
1902. Branegan, Jas. Aug., 555, North 16th Street, Philadelphia, Pa., U.S.A., Chemical Salesman.
- O.M. Branson, F. W., Wynneholme, Far Headingley, Leeds, Pharmaceutical Chemist.
1903. Brassard, Fred. A., 46, Vicar Lane, Bradford, Yorks, Aniline Dyestuff Importer.
1901. Brearley, Harry, c/o The Amalgams Co., Ltd., Attercliffe Road, Sheffield, Analytical Chemist.
1906. Breckenridge, John E., American Agricultural Chemical Co., Carteret, N.J., U.S.A., Chemist.
1888. Breffitt, Wm., Glasshoughton, Castleford, Yorks, Glass Manufacturer.
1908. Bregowsky, Ivan M., c/o Crane Co., 519, South Canal Street, Chicago, Ill., U.S.A., Chemist.
1905. Brettell-Vaughan, E., 22, Vardens Road, Battersea, S.W., Storage Battery Analyst.
1900. Brewis, E. T., 31, Belgrave Road, Leyton, E., Chemist.
1894. Breyer, Theodor, 603, Central Avenue, Wilmette, Ill., U.S.A., Chemist.
1885. Briant, L., 24, Holborn Viaduct, London, E.C., Analytical Chemist.
1890. Brierley, J. T., Highfield, Golden Hill, Leyland, near Preston, Lancs., Analytical Chemist.
1894. Briggs, J. Burnett, Vauxhall Soap Works, 6, Blackstock Street, Liverpool, Soap Manufacturer.
1893. Briggs, J. F., 2, Frankfort Road, Herne Hill, S.E., Technical Chemist.
1885. Briggs, T. Lynton, 188, Central Avenue, Flushing, Long Island, N.Y., U.S.A., Technical Chemist.
1905. Bristol, Dr. H. Stanley, U.S. Dept. of Agriculture, Forest Service, Washington, D.C., U.S.A., Chemist.
1886. Bristow, G. W., c/o Walter J. Crook, 10, Eastcheap, London, E.C., Chemical Manager.
1887. Broadbent, H., c/o Goodall, Backhouse, and Co., Sovereign Street, Leeds, Chemist.
1896. Broadhurst, W. Homer, 290, Lafayette Avenue, Brooklyn, N.Y., U.S.A., Chemist.
1889. Brock, Arthur, Firework Factory, Sutton, Surrey, Firework Manufacturer.
- O.M. Brock, J., Gwern-Tyno, Colwyn Bay, North Wales, Chairman of United Alkali Co., Ltd.
1896. Brooke, C. B., jun., Colne House, Brantham, near Manningtree, Xylonite Manufacturer.
1900. Brooke, Jno. R., Government Laboratory, Singapore, S.S., Chemist.
1884. Brookes, E. A., c/o The Chilian Mills Co., Ltd., Chiguayante, Concepcion, Chile, Chemist.
1895. Brookman, Fred. W., 6, West Street, Rochdale, Manure Works Manager.
1906. Brooks, Cecil J., c/o The Borneo Co., Ltd., Kuching, Sarawak, Metallurgist.
1907. Broome, James S., 18, Seedley Park Road, Pendleton, Manchester, Science Lecturer.
1901. Broome, Jos., 5, Webster Terrace, Roselle Park, N.J., U.S.A., Chemical Engineer.
1909. Brothers, Wm., S. Mayfield Road, Kersal, Salford, Chemical Manufacturer.
- O.M. Brotherton, E. A., M.P., Commercial Buildings, Leeds, Ammonia Distiller.
1884. Brown, Prof. A. Crum, F.R.S., S. Belgrave Crescent, Edinburgh, Professor of Chemistry.
1905. Brown, Prof. Adrian J., West Heath House, Northfield, near Birmingham, Professor of Brewing.

1892. Brown, A. H. M., 133, Kent Street, London, Ont., Canada, Metallurgist.
1891. Brown, Cesar R., 23, Gower Road, Forest Gate, E., Works Foreman.
- O.M. Brown, D., 93, Abbey Hill, Edinburgh, Chemical Manufacturer.
- O.M. Brown, D., Donaghmore, Tyrone, Ireland, Soap Manufacturer.
1890. Brown, Edw. Hilton, c/o W. Ropes and Co., St. Petersburg, Russia, Analytical Chemist.
1903. Brown, Frank C., P.O. Box 211, Framingham, Mass., U.S.A., Foreman.
1908. Brown, Francis Hammar, Wootton Wawen, Warwickshire, Engineer.
1894. Brown, Geo. E., c/o "The British Journal of Photography," 21, Wellington Street, Strand, London, W.C., Chemist.
1906. Brown, Harry E., Room 917, Du Pont Building, Wilmington, Del., U.S.A., Chemist.
1905. Brown, Hawthorne J., 507, Mansion House Chambers, Queen Victoria Street, London, E.C., Paper Maker.
- O.M. Brown, Henry, Benskin's Brewery, Watford, Herts., Brewing Chemist.
1899. Brown, Dr. Henry C., The Chemical Works, King's Lynn, Chemical Manufacturer.
- O.M. Brown, Dr. Horace T., F.R.S., 52, Neven Square, Kensington, S.W., Brewing Chemist.
1905. Brown, Hugh B., c/o Jas. Robertson & Sons, Ltd., Thrushgrove Works, Paisley, Chemist.
- O.M. Brown, Dr. J. Campbell, 8, Abercromby Square, Liverpool, Professor of Chemistry.
1891. Brown, J. Henry, Minas d'Aljustrel, Alemtejo, Portugal, Technical Chemist.
1901. Brown, Jos., Ashleigh House, Saville Town, Dewsbury, Manufacturing Chemist.
1905. Brown, Nicol, 4, The Grove, Highgate, N., Mining Director.
1906. Brown, Percy S., c/o Western Electric Co., West and Bethune Streets, New York City, U.S.A., Chemist.
1892. Brown, Reginald B., c/o Badische Co., Ltd., 2, Samuel Ogden Street, Manchester, Technical Chemist.
1889. Brown, Robt., The Firs, Hartford, Northwich, Engineer.
1901. Brown, Samuel B., Ruthven, Bowden Lane, Marple, Cheshire, Calico Printer.
- O.M. Brown, Walter, c/o Jas. H. Dennis and Co., Ltd., Widnes, Technical Chemist.
1900. Brown, Walter B., Victor Chemical Works, 89, Board of Trade Building, Chicago, Ill., U.S.A., Chemist and General Superintendent.
1901. Browne, Dr. Arthur L., 213, Cortland Street, Baltimore, Md., U.S.A., Analytical Chemist.
1906. Browne-Cave, E. J. C., "Strathallan," Bootle, Liverpool, Works Chemist.
1905. Browning, Prof. K. C., Medical College, Colombo, Ceylon, Professor of Chemistry.
- O.M. Browning, W., Broad Oak, Accrington, Calico Printer.
1901. Brownlie, David, 31, India Street, Alexandria, Dumbartonshire, Chemist.
1902. Brownrigg, Marcus P., Colonial Sugar Refining Co., Ltd., O'Connell Street, Sydney, N.S.W., Australia, Analytical Chemist.
1902. Brownson, Dr. H. W., King's Norton Metal Co., Ltd., Abbey Wood, Kent, Works Chemist.
1902. Bruce, Alex., Laboratory, Hyde Park Corner, Colombo, Ceylon, Chemist.
1908. Bruce, Robert, 44, High Street, Leven, Fifeshire, Works Chemist.
1900. Bruce, Wm. T., 3, Lombard Court, London, E.C., Director.
1892. Bruckmann, G. T., 109, 22nd Street, West New York, N.J., U.S.A., Chemical Engineer.
1905. Bruinier, A. G., 534, Canal Street, New York City, U.S.A., Agent for Kalle and Co.
- O.M. Brunner, H., Holly Mount, Tarboek Road, Huyton, near Liverpool, Chemical Manufacturer.
1894. Brunner, H. Bertram, The Hollies, Hartford, Cheshire, Chemist and Electrician.
1887. Brunner, J. F. L., M.P., c/o Brunner, Mond and Co., Ltd., 39, Victoria Street, London, S.W., Chemical Manufacturer.
- O.M. Brunner, Sir J. T., Bart., M.P., Silverlands, Chertsey; and (Journals) c/o Brunner, Mond and Co. Ltd., Northwich, Cheshire, Chemical Manufacturer.
1902. Brunner, Roscoe, The Winnington Hall Club, Winnington, Northwich, Alkali Manufacturer.
1894. Bruntun, J. Dixon, Wire Mill, Musselburgh, N.B., Wire Manufacturer.
1904. Bryant, Arthur P., c/o Clinton Sugar Refining Co., Clinton, Iowa, U.S.A., Chemist.
1903. Bryant, V. Seymour, Trelawne, Crowthorne, Berks., Analytical Chemist.
1908. Bryce, Chas. C., 43-45, Great Tower Street, London, E.C., Merchant.
1905. Bryce, Clarence H., c/o Benj. Moore and Co., 244, Water Street, Brooklyn, N.Y., U.S.A., Factory Superintendent.
1894. Bryce, Thos., Tharsis Mines, Huelva, Spain, Chemist.
1897. Bryson, Jas., Pumphorston Oil Works, Midcalder, N.B., Oil Works Manager.
1892. Buchanan, D. G., (Subs.) 40, St. Vincent Place, Glasgow, and (Journals) c/o La Asociacion Salitrera de Propaganda, Iquique, Chili, Analyst.
1908. Buchanan, Duncan G., 24, Gwynne Avenue, Parkdale, Toronto, Canada, Chemist (Rubber Works).
1904. Buchanan, E. F., 128, East Crescent Street, Marquette, Mich., U.S.A., Chemist.
1888. Buchanan, Jas., Caledonia Foundry, Brasenose Road, Liverpool, Engineer.
1904. Buchanan, John L., 3, The Wiend, Lower Bebington, Cheshire, Analytical Chemist.
1901. Buchanan, Joshua D., c/o Nobel's Explosives Co., Ltd., Polmont Station, N.B., Chemist.
1897. Buck, Chas. A., 521, Locust Street, South Bethlehem, Pa., U.S.A., Chief Chemist (Bethlehem Iron Co.).
1906. Buckie, Robert H., c/o West Virginia Paper and Pulp Co., Mechanicville, N.Y., U.S.A., Works Chemist.
1909. Buggy, Thos., Butte, Montana, U.S.A., Assayer and Chemist.
1900. Bull, Dr. Benjamin S., 104, Humber Road, Blackheath, S.E., Technical Chemist.
1902. Bull, Irving C., 100, Maiden Lane, New York City, U.S.A., Chemist.
1899. Bull, Herbert J., 18, Billiter Street, London, E.C., Chemist.
1907. Bult, Stanley R., 18, Billiter Street, London, E.C., Chemist.
- O.M. Bumby, H., Coltness Ironworks, Newmains, N.B., Ironworks Manager.
- O.M. Bunker, H. E., 19, Napier Street, Toronto, Ont., Canada, Technical Chemist.
1901. Bunting, Henry H., Oficina de Ensayes F. C. C. del P., Callao, Peru, Analyst.
1894. Bunting, W., Lightfoot, Forest Bank, Crawshawbooth, near Manchester, Calico Printer.
1893. Burbridge, Jas., India-rubber Mills, Tottenham, N., India-rubber Manufacturer.
1886. Burdekin, G., jun., 10, Clifton Terrace, St. Helens, Lancashire, Chemical Works Manager.
1896. Burford, Samuel F., Beechworth, Stoneygate Road, Leicester, Analytical Chemist.
1889. Bürger, Dr. J. L., Birch Avenue, Talbot Road, Old Trafford, Manchester, Technical Chemist.
1901. Burgess, Prof. C. F., University of Wisconsin, Madison, Wis., U.S.A., Electro-chemical Engineer.
1889. Burgess, Geo., Pitville, Hale Road, Ditton, Widnes, Chemist.
1889. Burgess, Wm. T., 26, Priory Road, Bedford Park, London, W., Analytical Chemist.
1902. Burkard, Dr. Ernst, The Heyden Chemical Works, Garfield, N.J., U.S.A., Chemist.
1899. Burkhardt, Dr. G. A., c/o Bohrgesellschaft Erkelenz, Erkelenz, Rheinland, Germany, Chemist.
1897. Burland, Lt.-Col. Jeffrey H., 824, Sherbrooke Street, Montreal, Canada, Paper and Card Manufacturer.

1897. Burls, Frank B., 4, Dyer's Hall Road, Leytonstone, Essex, Chemist.
1898. Burls, Herbert T., (Journals) c/o Royal Societies Club, St. James Street, S.W., and (communications) c/o H. S. King & Sons, Cornhill, E.C., Mechanical Engineer.
1901. Burnand, Sydney, Manbié Saccharine Co., Ltd., Hammermith, W., Manager.
- O.M. Burnard, R., Plymouth Chemical Works, Plymouth, Chemical Manufacturer.
1891. Burnet, Henry K., North Brook Vitriol Works, Bradford, Yorks., Sulphuric Acid Maker.
1897. Burnet, Jno. Jas., 18, University Avenue, Glasgow, Architect.
1907. Burnham, Frank E., c/o Avery Chemical Co., 7, Sears Street, Boston, Mass., U.S.A., Chemist.
1893. Burnham, J. C., Cordite Factory, Aruvankad, Nilgiri Hills, India, Analytical Chemist.
1900. Burnside, Chas. F., Du Pont Building, Wilmington, Del., U.S.A., Chemist.
1900. Barr, Edmund C., 1722, Vallejo Street, San Francisco, Cal., U.S.A., Manufacturer.
- O.M. Burrell, B.A., 8, Springfield Mount, Leeds, Analytical Chemist.
1906. Burrough, Ernest J., Cale Distillery, Hutton Road, Lambeth, S.E., Rectifier.
1892. Burrough, Horace, jun., 509, West Lombard Street, Baltimore, Md., U.S.A., Technical Chemist.
1888. Burrows, Edw., Home Villa, Low Fell, Gateshead-on-Tyne, Alkali Works Manager.
1903. Burton, Alf., 44, York Street, Toronto, Canada, Dyer and Finisher.
1905. Burton, Jas. K., Grand and 20th Avenues, Nashville, Tenn., U.S.A., Consulting Chemist.
1903. Burton, Jno., 2, Green Street, Bethnal Green, E., Dye and Chemical Manufacturer.
1904. Burton, T. R., c/o Scott, Greenwood and Son, S. Broadway, Ludgate Hill, London, E.C., Technical Journalist.
1889. Burton, Wm., The Hollies, Clifton Junction, near Manchester, Potter's Chemist.
1897. Burwell, A. W., Box 1193, Helena, Montana, U.S.A., Consulting Chemist.
1906. Busby, Fred. E., Arnold Print Works, North Adams, Mass., U.S.A., Chemist.
1897. Bush, J. M., c/o W. J. Bush and Co., Ltd., Ash Grove, Hackney, E., Manufacturing Chemist.
1897. Butler, David B., 41, Old Queen Street, Westminster, S.W., Cement Expert.
1903. Butler, Fredk., Ditchfield Road, Hough Green, near Widnes, Manager (Ditto Copper Works).
1890. Bntler, Paul, Lowell, Mass., U.S.A., Ammunition Manufacturer.
1885. Butler, Samuel, The Cedars, Compton, Wolverhampton, Brewer.
1905. Butler, T. H., Chamwood, Cotham Park, Bristol, Chemical Student.
1886. Butler, W. W., c/o Mitchells & Butlers, Ltd., The Brewery Library, Cape Hill, Birmingham, Brewer.
- O.M. Butterfield, J. C., 79, Endlesham Road, Balham, S.W., Analytical Chemist.
1892. Butterfield, W. J. A., 66, Victoria Street, Westminster, S.W., Analytical Chemist.
1897. Butters, Charles, 54, New Broad Street, London, E.C., and (Journals) Roselawn, Berkeley, Cal., U.S.A., Metallurgist.
1900. Butterworth, Elwell R., c/o Reversible Collar Co., 111, Putnam Avenue, Cambridge, Mass., U.S.A., Chemist.
1902. Butterworth, F. J., 122, Second Avenue, Newark, N.J., U.S.A., Chemist.
1892. Buttfield, Horace V., 13, Wellington Road, Bush Hill Park, Enfield, N., Chemical Demonstrator.
- O.M. Byard, A. G., c/o Burt, Boulton, and Haywood, Apartado 8, Bilbao, Spain, Technical Chemist.
1905. Byrne, F. A., 2, Ludgate Hill, Birmingham, Director of Chemical Co.
1899. Byrnes, Dr. Eugene A., 918, F. Street N.W., Washington, D.C., U.S.A., Patent Lawyer.
1893. Byrom, T. H., Laboratory, Wigan Coal and Iron Co., Wigan, Analytical Chemist.
1887. Bythway, M., 44, Lloyd Street, Albert Square, Manchester, Drysalter.

C

1884. Cabot, Godfrey L., 940, Old South Building, Boston, Mass., U.S.A., Manufacturing Chemist.
1907. Cabot, Samuel, 141, Milk Street, Boston, Mass., U.S.A., Chemical Manufacturer.
1906. Caddick, Arthur, Arboretum Lodge, Sewell Road, Lincoln, Works Chemist.
1889. Cadett, Jas., Ashtead, Surrey, Chemical Engineer.
1905. Cain, Dr. J. C., 28, Pembury Road, Lower Clapton, N.E., Colour Chemist.
1891. Caines, G. S. A., 7, Rochester Terrace, Camden Road, London, N.W., Analytical Chemist.
1907. Cairncross, W. M., c/o Manica Copper Development Co., Macequece, Portuguese East Africa, Mining Engineer.
1897. Cairns, Wm., 5, Carlton Place, Glasgow, Plumber.
1907. Caistor, J. W. Y., Morro Velho, Villa Nova de Lima, Minas Geraes, Brazil, Chemist.
1891. Caldecott, W. Arthur, Box 1167, Johannesburg, Transvaal, South Africa, Metallurgist.
1905. Calder, Prof. Edwin E., Long Meadow, R.I., U.S.A., Professor of Chemistry.
1897. Calder, W. A. S., Ormidale, Little Moor Hill, Smethwick, Birmingham, Chemical Manufacturer.
1908. Caldwell, Robert J., The Poplars, Bowes Road, New Southgate, N., Chemist and Works Manager.
1888. Caldwell, Wm., Murray Street, Paisley, N.B., Drysalter.
1902. Calm, Dr. Chas. E., 41-43, Warren Street, New York City, U.S.A., Manufacturing Chemist.
1904. Calvert, Dr. Harry T., West Riding of Yorkshire Rivers Board, Wakefield, Chemist.
1895. Cambier, Jacob, 1401, Carteret Avenue, Pueblo, Colo., U.S.A., Chemist.
1908. Cameron, H. Lovett, c/o Vale and Cameron, 20, Castlereagh Street, Sydney, N.S.W., Assayer.
1891. Cameron, Jas., 70, Old Chester Road, Woodhey, Rock Ferry, Cheshire, Manufacturing Confectioner.
1904. Cameron, Walter S., 239, West 136th Street, New York City, U.S.A., Manufacturing Perfumer.
1908. Cameron, Wm., Balik Papan, Dutch East Borneo, Sugar Refinery Manager.
- O.M. Cammack, J., 34, Wolseley Road, St. Helens, Lancashire, Technical Chemist.
1886. Campbell, Andrew, c/o Burnah Oil Co., Ltd., Durne-daw, Rangoon, Burmah, Analytical Chemist.
- O.M. Campbell, Archibald, Berry Lodge, Rugeley, Staffordshire, Technical Chemist.
1902. Campbell, Ashley, Colonial Sugar Refining Co., Ltd., Pyrmont Refinery, Sydney, N.S.W., Australia, Analytical Chemist.
1908. Campbell, Fred. A., The Working Men's College, Latrobe Street, Melbourne, Victoria, Australia, Principal.
1906. Campbell, Geo. H., 75, Yonge Street, Toronto, Canada, Manufacturing Chemist.
1907. Campbell, John A., c/o British South African Explosives Co., Modderfontein, Transvaal, Chemist.
1901. Campbell, Kenneth F., M.Inst.C.E., 1, Peel Street, Huddersfield, Civil Engineer.
1908. Campbell, Max E., 629, Laughlin Building, Los Angeles, Cal., U.S.A., Chemist.
1909. Campbell, Robt., The Nairn Linoleum Co., P.O. Box 32, Newark, N.J., U.S.A., Linoleum Manufacturer.
1909. Campbell, Steve, The Nairn Linoleum Co., P.O. Box 32, Newark, N.J., U.S.A., Linoleum Manufacturer.
1904. Campion, A., Laboratory, 144, Wellington Street, Glasgow, Chemist and Metallurgist.

1897. Cannell, F. D., jun., c/o Cuban Sugar Refining Co., Cardenas, Cuba, Sugar Refiner.
1908. Canning, Ernest R., 137, Great Hampton Street, Birmingham, Manufacturer.
1893. Cannon, J. C., Staverton House, Shoreham, Sussex; and (Jnls.) Waldemar, The Parade, Sandown, I.W., Analyst.
- O.M. Cannon, M., 25, Stormont Road, Clapham Common, S.W., Vinegar Works Manager.
1891. Canziani, Enrico, 3, Palace Green, Kensington, W., Civil Engineer.
1891. Carden, Albert J., Danster House, 12, Mark Lane, London, E.C., Distiller.
1893. Carey, Arthur, The Groves, Grassendale Park, near Liverpool, Chemist.
- O.M. Carey, Eustace, The United Alkali Co., Ltd., 30, James Street, Liverpool; and (Journals) The Groves, Grassendale Park, near Liverpool, Chemical Manufacturer.
1906. Carey, William G., c/o Clinical Research Assoc., Watergate House, Adelphi, London, W.C., Chemist.
1904. Cargill, J. T., c/o Finlay, Fleming, and Co., Rangoon, Burmah, East India Merchant.
1907. Carlitz, Joseph S., 1017, Callowhill Street, Philadelphia, Pa., U.S.A., Chemist.
1896. Carmichael, Herbert, Bureau of Mines, Victoria, British Columbia, Public Analyst and Assayer.
1884. Carmody, Prof. Patrick, Government Laboratory, Port of Spain, Trinidad, Analytical Chemist.
1897. Carnell, Wm. C., c/o Tacony Chemical Works, Bridesburg, Philadelphia, Pa., U.S.A., Chemist.
- O.M. Caro, Dr. H., C. S. N. 9, Mannheim, Baden, Germany, Technical Chemist.
1906. Caro, Dr. Nikodem, Meinekestrasse 20, Berlin, Germany, Analytical Chemist.
1893. Carpenter, C. C., South Metropolitan Gas Co., 709A, Old Kent Road, London, S.E., Civil Engineer.
1908. Carpenter, Edwin P., Culvert Works, Sheepeat Lane, Battersea, S.W., Manager of Casein, Ltd.
1900. Carpenter, Frank B., 11, South 12th Street, Richmond, Va., U.S.A., Chemist.
1900. Carpenter, Harry B., c/o Lister's Agricultural Chemical Works, Newark, N.J., U.S.A.
- O.M. Carpenter, R. Forbes, Prestwich, Greeneroft Gardens, West Hampstead, N.W., Chief Inspector under the Alkali, &c., Works Acts.
1904. Carr, Francis H., Kelvin, Church Avenue, Sidcup, and (Journals), Burroughs, Wellecome, and Co., Ltd., Dartford, Kent, Manufacturing Chemist.
1907. Carrier, C. F., jun., 511, Union Place, Elmira, N.Y., U.S.A., Manufacturing Chemist.
1904. Carroll, Jno. L., 23, Division Place, Newark, N.J., U.S.A., Secretary (American Oil and Supply Co.).
- O.M. Carteighe, M., Oriel, Goring-on-Thames, Pharmaceutical Chemist.
1904. Carter, A., Cuba Street, Petone, Wellington, New Zealand, Works Manager.
1905. Carter, Robert A., c/o Roessler and Hasslaicher Chemical Co., Box 68, South Amboy, N.J., U.S.A., Chemist.
1895. Carter, Stewart F., Glenlyon Dyeworks, Saylesville, R.I., U.S.A., Technical Chemist.
1903. Carter, Thomas, 322, Scarr Hill, Bradford, Yorks, Works Chemist.
1886. Carter, W. Chas., c/o Dominion Iron and Steel Co., Sydney, C.B., Canada, Analytical Chemist.
1889. Carulla, F. J. R., 84, Rose Hill Street, Derby, Chemical Manufacturer.
1906. Carveth, Dr. H. R., Niagara Electrochemical Co., Niagara Falls, N.Y., U.S.A., Works Manager.
1903. Caspari, Dr. W. A., 23, Sefton Park Road, Liverpool, Chemist and Physicist.
1895. Catlin, Chas. A., 133, Hope Street, Providence, R.I., U.S.A., Chemist (Rumford Chemical Works).
1896. Caven, Robt. M., University College, Nottingham, Lecturer in Chemistry.
- O.M. Cawley, G., 25, Victoria Street, Westminster, S.W., Chemical Engineer.
- O.M. Cawley, J., 278, Passaic Street, Newark, N.J., U.S.A., Analytical Chemist.
1897. Cawley, Thos. A., British Gelatin Works, New Bedford Road, Luton, Gelatin Manufacturer.
1902. Cerasoli, Albarto, c/o Dr. L. Mond, 18, Avenue Road, Regent's Park, N.W., Engineer.
1891. Chadwick, Walter M., Thorneycroft, Westoe, South Shields, Chemical Works Manager.
1894. Chaloner, G. W., 26, Eagle Wharf Road, Hoxton, N., Chemical Manager.
1901. Chamberlain, G. E., 42, East Madison Street, Chicago, Ill., U.S.A., Chemist.
1902. Champion, Edmund C., 510, South Washington Avenue, Topeka, Kansas, U.S.A., Chemist.
- O.M. Chance, A. M., Chemical Works, Oldbury, near Birmingham, Chemical Manufacturer.
- O.M. Chandler, Dr. C. F., Columbia University, West 116th Street, New York City, U.S.A., Professor of Chemistry.
1907. Chancy, Walter, The Gas Works, Neechells, Birmingham, Gas Engineer.
1893. Chaplin, Dr. Edw. M., Public Analyst's Laboratory, Wakefield, Yorks, Analytical Chemist.
1906. Chaplin, Wm. H., 13, Penywern Road, Earl's Court, London, S.W., Wine Merchant.
1890. Chapman, Alf. Chaston, 8, Duke Street, Aldgate, E.C., Analytical Chemist.
1906. Chapman, Arthur J., Baronsmere, Stanhope Avenue, Church End, Finchley, N., Analytical Chemist.
1906. Chapman, E. A., 96, Henley Road, Ilford, E., Works Chemist.
1903. Chapman, Geo. W., Swift Fertilizer Works, 912, Prudential Building, Atlanta, Ga., U.S.A., Superintendent.
- O.M. Chapman, Spencer, 36, Mark Lane, E.C., Chemical Manufacturer.
1894. Charlier, A. C. J., 6, Talbot Road, South Tottenham, N., Consulting Chemist.
1902. Charlton, Thos., 252, Irvington Place, Denver, Colo., U.S.A., Manufacturing Chemist.
1900. Chase, March F., c/o Mineral Point Zinc Co., Depue, Ill., U.S.A., Chemist.
1889. Chase, R. L., Arnold Printworks, North Adams, Mass., U.S.A., Manager.
1898. Chattock, Herbert E., 23, Apsley Road, Clifton, Bristol, Oilcake Manufacturer.
1905. Cheesman, Frank P., 100, William Street, New York City, U.S.A., Paint Manufacturer.
1901. Cheetham, Howard, 18, St. Ann Street, Manchester, Chartered Patent Agent.
1894. Cheney, J. P., c/o Cheney Bros., South Manchester, Conn., U.S.A., Silk Manufacturer's Chemist.
1905. Chick, Oliver, 52, High Street, Hornsey, N., Analytical Chemist.
1907. Chickering, H. C., c/o E. I. du Pont de Nemours Powder Co., Lewisburg, Ala., U.S.A., Chemist.
1893. Cholerton, A. F., 40½, Belgrave Gate, Leicester, Manufacturing Chemist.
1890. Chorley, Jno. C., Bewsey, Oxford Road, Birkdale, Lanes., Analytical Chemist.
- O.M. Christie, J., Leventfield, Alexandria, N.B., Dyer and Printer.
1903. Christie, John, c/o The New Explosives Co., Ltd., Stowmarket, Suffolk, Analytical Chemist.
1908. Christie, Malcolm, Ardenlea, Portland Road, Hamilton, N.B., Analytical Chemist.
1898. Christison, Geo., 13, Cambridge Drive, Glasgow, Engineer.
1907. Christopher, George, Walkden Works, Verney Road, South Bermondsey, S.E., Consulting Chemist.
1907. Christopher, J. E., Solvay Coke Works, Kirkless, Wigan, Assistant in Charge.
- O.M. Chrystal, W. J., 7, West George Street, Glasgow, Chemical Manufacturer.
1908. Chrystall, E. R., c/o Curtis's & Harvey, Ltd., Cliffe at Hoo, Kent, Research Chemist.
1904. Chubb, H. M., Wharfedale Villas, Tadcaster, Yorks., Brewery Chemist.
- O.M. Church, Professor A. H., F.R.S., Shelsley, Kew, Surrey, Professor of Chemistry in the Royal Academy.

1890. Church, Elihu D., jun., 63, Wall Street, New York City, U.S.A., Soda Manufacturer.
1906. Church, Sumner R., c/o Barrett Manufacturing Co., 17, Battery Place, New York City, U.S.A., Chemical Engineer.
1907. Churchill, Wm., Corning Glass Works, Corning, N.Y., U.S.A., Chemist.
1896. Cladlin, Alan A., (Communications) 88, Broad Street, Boston; and (Journals) Littleton, Mass., U.S.A., Manufacturing Chemist.
1900. Clamer, Guiliam H., 46, Richmond Street, Philadelphia, Pa., U.S.A., Chemist.
1885. Clanahan, H. C., 79, Mosley Street, Manchester, Chemical Merchant.
1901. Clapham, Henry E., 15, St. Julian's Road, Kilburn, N.W., Technical Chemist.
1905. Clapp, Geo. A., 503, Walnut Street, Newtonville, Mass., U.S.A., Chemist.
1891. Clapp, Ralph R., c/o Standard Ammonia Co., Ltd., Sussex Wharf, East Greenwich, S.E., Manager.
1889. Clapperton, J., jun., Analytical Chemist.
1903. Clare, Henry, Hepscott, Morpeth, Northumberland, Schoolmaster.
1905. Clark, Alfred N., Box 168, Wallaceburg, Ont., Canada, Technical Chemist and Engineer.
1906. Clark, Allan J., c/o Homestake Mining Co., Lead, South Dakota, U.S.A., Metallurgist.
1904. Clark, Arthur W., c/o Johnson and Johnson, New Brunswick, N.J., U.S.A., Chemist and Bacteriologist.
1908. Clark, Chas. T., P.O. Box 422, Sault Ste. Marie, Ont., Canada, Manufacturing Chemist.
1896. Clark, Donald, School of Mines, Bendigo, Victoria, Australia, Director.
1904. Clark, Prof. Friend E., Central University of Kentucky, Danville, Ky., U.S.A., Professor of Chemistry.
1900. Clark, Jno., Broadway Works, Millwall Dock, London, E., Manufacturing Chemist.
1906. Clark, M. H., c/o Boston Rubber Shoe Co., Malden, Mass., U.S.A., Chemist.
1902. Clark, Robt. M., 138, Bath Street, Glasgow, Chemist.
1906. Clark, Wm. B., 42, Robertson Street, Greenock, Chemist.
1907. Clark, Wm. H., 78, Warrington Road, Elswick Road, Newcastle-on-Tyne, Analytical Chemist.
1903. Clark, Dr. W. Inglis, 104, South Canongate, Edinburgh, Manufacturing Chemist.
1904. Clarke, Alfred R., 613-617, Eastern Avenue, Toronto, Canada, Leather Manufacturer.
1908. Clarke, Arthur F., 13, Sloane Street, London, S.W., Analytical Chemist.
1908. Clarke, Dr. Latham, Boylston Hall, Harvard University, Cambridge, Mass., U.S.A., Instructor in Chemistry.
1903. Clarke, Robt. W., 3, Aberdeen Villas, Chase Road, Southgate, N., Analyst.
1897. Clarke, Wm. B., c/o Edison-Swan U.E.L. Co., Ltd., Ponders End, N., Electro-Chemist.
1908. Clarke, Wm. H. J., 16, Harley Street, North Perth, West Australia, Asst. Analyst (Govt. Lab.).
- O.M. Claudet, A. C., 6 & 7, Coleman Street, E.C., Metallurgist.
1889. Claus, Wm. H., c/o Claus and Co., Ltd, Clayton, Manchester, Manufacturing Chemist.
- O.M. Clayton, E. G., Chemical Laboratory, 23, Holborn Viaduct, London, E.C., Consulting Chemist.
1895. Clayton, Dr. G. C., Etonfield, Wavertree, Liverpool.
1909. Clayton, H., 15, North Cray Road, Bexley, Kent, Technical Chemist.
1894. Clayton, Robt. H., Woodleigh, Blackfield Lane, Kersal, Manchester, Chemist.
1905. Clayton, W. E., Royal Victoria Yard, Deptford, S.E., Superintendent.
1907. Clement, Leonard, Beamsley, Fairhaven, near Lytham, Lanes., Chemist.
1893. Clemes, J. H., Cheriton, Newquay, Cornwall.
1886. Cleminshaw, E., Alkali Works, Oldbury, near Birmingham, Technical Chemist.
1884. Clerk, Dugald, F.R.S., 18, Southampton Buildings, Chancery Lane, W.C., Engineer.
1899. Cleveland, D. B., 1856, East 63rd Street, N.E., Cleveland, Ohio, U.S.A., Chemist.
1905. Clexton, Thos. J., 285, Congress Street, Boston, Mass., U.S.A., Manager (A. Klipstein & Co.).
1906. Clifford, Jos., Ivy House, Prosbury, near Macclesfield, Chemist.
1900. Clifford, Wm., Sewage Outfall Works, Wolverhampton, Sewage Works Manager.
- O.M. Cloud, T. C., 4, Lloyd's Avenue, Finchurch Street, London, E.C., Metallurgist.
- O.M. Clowes, Dr. F., 40, Craven Street, Charing Cross, W.C.; and the Grange, College Road, Dulwich, S.E., Chief Chemist (L.C.C.).
1891. Clutton, J. H., Poste Restante, Lastours (Aude), France, Assayer.
1899. Coates, Chas. E., jun., Louisiana State University, Baton Rouge, La., U.S.A., Professor of Chemistry.
1888. Coats, Jno. T., 105, Broughton Street, Edinburgh, Manufacturing Chemist.
1893. Cobb, Jno. W., Farnley Ironworks, near Leeds, Technical Assistant to Managing Director.
1904. Coblenz, Lambert, 1708, Sutter Street, San Francisco, Cal., U.S.A., Chemist.
1894. Coblenz, Dr. Virgil, College of Pharmacy, 115, West 68th Street, New York City, U.S.A., Professor of Chemistry.
1899. Cochran, Alfred, 559, Madison Street, Brooklyn, N.Y., U.S.A., Chemist.
1901. Cockburn, John A., c/o Japanese Explosives Co., Ltd., Hiratsuka, Sagami, Japan, Analytical Chemist.
1902. Cocking, Allan T., Carhampton House, Four Oaks, Sutton Coldfield, Ammunition Manufacturer.
1905. Coes, Chas. S., 119, East River Street, Hyde Park, Mass., U.S.A., Oil Chemist.
1903. Cofman-Nicoresti, J., 24, St. Gabriel's Road, Cricklewood, N.W., Chemist.
1903. Coggeshall, Dr. G. W., Chestnut Street, Dedham, Mass., U.S.A., Chemical Manufacturer.
1887. Coghill, P. de G., Borax Works, Old Swan, Liverpool, Technical Chemist.
1884. Cogswell, W. B., Syracuse, N.Y., U.S.A., Chemical Engineer.
- O.M. Cohen, Dr. J., 13, Cardigan Road, Leeds, Analytical Chemist.
1897. Cohn, Alfred J., 122, East 74th Street, New York City, U.S.A., Chemist.
1901. Cohn, Sigmund, 13, Dutch Street, New York City, U.S.A., Metallurgical Chemist.
1904. Cohoe, Prof. W. P., 148, Van Horne Street, Toronto, Canada, Professor of Chemistry.
1903. Colbert, W., British S.A. Dynamite Factory, Modderfontein, Transvaal, Analytical Chemist.
1891. Colby, Albert L., 447, Lehigh Street, South Bethlehem, Pa., U.S.A., Metallurgical Engineer.
1899. Colby, E. A., Baker Platinum Works, Newark, N.J., U.S.A., Metallurgical Chemist.
- O.M. Colby, W. H., Carreg-wen, Aberystwith, Wales.
1893. Coleman, W. H., 18, Egerton Road, Fallowfield, Manchester, Tar Works Chemist.
- O.M. Collens, E., Vinegar Works, Stourport, Worcestershire, Manager.
1905. Collett, John H., Hillfield, and (Jnls.) The Librarian, Free Library, Gloucester, Chemical Manufacturer.
1887. Collett, J. M., Hillfield, Gloucester, Chemical Manufacturer.
1901. Colley, Bernard T., c/o Velardena M. and S. Co., Velardena, Durango, Mexico, Assayer.
1908. Collier, F. C., 437, Lansdowne Avenue, Westmount, Montreal, Canada, Analytical Chemist.
1903. Collier, Pierre, Companhia Industrial Pernambucoana, Pernambuco, Brazil, Civil Engineer.
1893. Collin, Dr. C. A., Ferguslie Threadworks, Paisley, N.B., Textile Chemist.
1898. Collingridge, Frank, 73, Fountain Road, Edgbaston, Birmingham, Chemist.
1883. Collins, J. H., Crinnis, Par Station, Cornwall, Technical Chemist.
1899. Collins, S. Hoare, Armstrong College, Newcastle-on-Tyne, Agricultural Chemist.

1888. Collins, W. Hepworth, c/o Edw. Wihl & Co., 17, Nicholas Street, Manchester, Analytical Chemist.
1899. Collis, Walter T., 89, Greenfield Road, Harborne, Birmingham, Chemist.
1891. Colman, Dr. H. G., Elmside, Worcester Park, Surrey, Analytical Chemist.
1892. Colquhoun, Ludovic, Dynamite Factory, Modderfontein, Transvaal, Analytical Chemist.
1894. Colquhoun, W., Solvay Chambers, Gell Street, Sheffield, Engineer.
1901. Colwell, J. Kear, Finsbury Town Hall, Rosebery Avenue, E.C., Analytical and Consulting Chemist.
1906. Comber, A. W., Suramangalam, Salem District, South India, Manager (Magnesite Works).
1900. Comey, Arthur M., 424, East 13th Street, Chester, Pa., U.S.A., Technical Chemist.
1906. Compton, Miss N. J., Library, University of Nebraska, Lincoln, Neb., U.S.A., Librarian.
1906. Condit, Louis C., Chemical Laboratory, B. and O. R. R., Mount Clare, Baltimore, Md., U.S.A., Chemist.
1901. Connah, Jas., Laboratory, Custom House, London, E.C., Government Analyst.
1905. Conner, Arthur B., 1070, Fort St. West, Detroit, Mich., U.S.A., Chemist.
1883. Connor, C. C., 10, College Gardens, Belfast, Ireland, Chemist.
1891. Conradson, Pontus H., Galena Oil Works, Franklin, Pa., U.S.A., Analytical Chemist.
1906. Conrau, Oliver, Dansk Svøfvelsøye och Superfosfatfabrik, Mandelstrup, Denmark, Administrator.
1889. Conroy, Dr. Jas. T., Adirondack, Grassendale Park, Liverpool, Chemist.
1887. Constable, W. H., Australian Alum Works, Runcorn, Analytical Chemist.
1908. Conyngham, Wm. Boulton, 78, Hudson Street, New York City, U.S.A., Pharmaceutical Chemist.
- O.M. Cook, H. J., The Firs, Woodford Green, Essex, Soap Manufacturer.
1903. Cook, Jas. W., London and Provincial Dye Works, Hackney Wick, N.E., Dyer.
1899. Cook, Robt. A., New Brunswick, N.J., U.S.A., Chemist.
1898. Cook, Thos. Alex., East London Soap Works, Bow, E., Soapmaker.
1899. Cook, Walter G., 9, Hendon Lane, Finchley, N., Analytical Chemist.
1891. Cooke, Arthur W., c/o Brotherton and Co., Ltd., Holmes Street, Dewsbury Road, Leeds, Analytical Chemist.
1907. Cooke, J. J. Verdin, 9, James Street, Liverpool, Salt Manufacturer.
1904. Cooke, W. Ternent, The University, Adelaide, South Australia, Lecturer in Chemistry.
1901. Cooper, T. S., 36, Demesne Road, Alexandra Park, Manchester, Calico Printing Chemist.
1891. Cooper, Walter J., The Elms, Lavernock, South Wales, Cement Works Manager.
1907. Cooper, W. F., Research Laboratory, Water Lane, Watford, Synthetic Chemist.
1890. Corcoran, Bryan, 31, Mark Lane, London, E.C., Chemical Engineer.
1905. Cormack, Wm., c/o G. Nelson, Dale and Co., Ltd., Embsote Mills, Warwick, Chemist.
1899. Cornelison, Dr. Robt. W., Bloomfield, N.J., U.S.A., Consulting Chemist.
1906. Cornwell, R. de Vere, Salisbury, Rhodesia, Chemist.
1889. Corrie, David, c/o Nobel's Explosives Co., Ltd., Polmont Station, N.B., Technical Chemist.
1894. Coste, J. H., 40, Craven Street, W.C., and (Journals) Utopia, Gloucester Road, Teddington, Analytical Chemist.
1891. Cotton, W. F., Hollywood, Dandrum, Co. Dublin, Gas Works Manager.
1906. Coupe, Miles, Rosebank, Thornfield Road, Waterfoot, near Manchester, Chemist.
1894. Court, Heywood, Staveley, Chesterfield, Analytical Chemist.
1898. Courtney, Samuel, Bizerta, Knockdene Park, Belfast, Ireland, Manager.
1909. Consins, Christopher C., 506, New York Life Building, Montreal, Canada, Patent Solicitor.
1894. Cousins, W. J., 17, Temple Chambers, Temple Avenue, E.C., Consulting Chemist and Director.
1903. Cowan, A. Wallace, c/o Redpath, Brown, & Co., Ltd., Riverside Works, East Greenwich, S.E., Analytical Chemist.
1906. Cowan, George D., Bridge House, Bridge Road, Millwall, E., Manager, Desilverising Works.
1893. Cowan, W. J., 12, Park Avenue, Wood Green, N., Fine Colour Manufacturer.
1897. Cowburn, Arthur W., 29, Princess Street, Manchester, Chemical Merchant and Analytical Chemist.
1907. Cowburn, J. Robert, 10, Eastwood Road, South Woodford, Essex, Technical Chemist.
1904. Cowee, Harvey D., 161, River Street, Troy, N.Y., U.S.A., Chemist.
1891. Cowper-Coles, Sherard Osborn, Grosvenor Mansions, Victoria Street, Westminster, S.W., Metallurgical Engineer.
1905. Cox, Harold N., c/o Lalance & Grosjean Mfg. Co., Woodhaven, N.Y., U.S.A., Chemist.
1884. Craig, Geo., Chemical Laboratory, 95, Bath Street, Glasgow, Technical Chemist.
1895. Craig, Thos. J. L., c/o Peter Spence & Sons, Ltd., Alum Works, Manchester, Chemist.
1908. Craig, Wm. J., 7, Scott Street, Garnethill, Glasgow, Analytical Chemist.
1901. Crane, Fred. D., 28, Hillside Avenue, Montclair, N.J., U.S.A., Consulting Chemist.
1902. Crane, Jasper E., c/o The Arlington Co., Arlington, N.J., U.S.A., Chemist.
1898. Cranfield, Wm., 11, Avondale Place, Halifax, Yorks, Teacher of Chemistry.
1903. Crammer, Ridgeway, 170, 88th Street, Bay Ridge, Brooklyn, N.Y., U.S.A., Chemist.
1902. Craven, Alfd. B., 20, Edinborough Road, Upper Armley, Leeds, Analytical Chemist.
1899. Craven, Jas., c/o American Creosoting Co., Springfield, Mo., U.S.A., Chemist.
1906. Craven, J. A., 119, Town Street, Armley, Leeds, Chemist.
1891. Craven, Jno., jun., Netherlands, Broughton Park, Manchester, Chemist.
1906. Craven, John I., 141, Wilmer Road, Heaton, Bradford, Chemist and Salesman.
1885. Craw, John, 15, Cadogan Street, Glasgow, Drysalter.
- O.M. Crawford, D., Langdale's Chemical Manure Co., Ltd., St. Lawrence, Newcastle-on-Tyne, Manager.
1908. Crawford, Lawrence, Lugar Iron Works, Old Cumnock, Ayrshire, N.B., Analytical Chemist.
1890. Crawshaw, E., 25, Tollington Park, London, N., Dye Merchant.
- O.M. Cresswell, C. G., Ermyngarth, Ashted, Surrey; and 9, Bridge Street, Westminster, S.W., Chemist.
1901. Cribb, Cecil H., 136, Shaftesbury Avenue, London, W., Analytical and Consulting Chemist.
1908. Crighton, Adam M., Wood Cottage, Middleton, Manchester, Calico Printer's Chemist.
1905. Crighton, W. H., c/o Ore Concentration Co., Ltd., Glebe Road, Kingsland Road, London, N.E., Chemist.
1890. Criper, Wm. R., c/o Messrs. D. Weldie and Co., Konnagar, near Calcutta, India, Manufacturing Chemist.
1908. Crites, Bert O., 1341, East 89th St. N.E., Cleveland, Ohio, U.S.A., Chemist.
1902. Croasdale, Dr. Stuart, 1574, York Street, Denver, Colo., U.S.A., Mining Engineer and Metallurgist.
1908. Croubie, W. A. E., 1, Westwood Park, Forest Hill, S.E., Consulting Engineer.
1889. Cronquist, Prof. A. Werner, Stocksund, Stockholm, Sweden, Inspector-General of Explosives.
1901. Cronquist, G. W., Hyllinge, Grufva, Sweden, Fire-Brick Works Manager.
- O.M. Crookes, Sir Wm., F.R.S., 7, Kensington Park Gardens, Notting Hill, W., Analytical Chemist.
1896. Crosby, Thos., Llanelly Steelworks, Llanelly, South Wales, Metallurgist.

- O.M. Crostfield, A. L., 46, Bidston Road, Oxtou, Birkenhead, (Journals) c/o Prof. B. Moore, Biochemical Dept., The University, Liverpool, Analytical Chemist and Assayer.
1896. Crostfield, Capt. G. R., Volunteer Quarters, Sankey Street, Warrington, Soap Manufacturer.
1908. Crosland, Percy F., The University, Leeds, Technical Chemist.
1884. Cross, C. F., 4, New Court, Lincoln's Inn, London, W.C., Analytical Chemist.
1894. Crossley, Prof. Arthur W., Pharmaceutical Society, 17, Bloomsbury Square, London, W.C., Professor of Chemistry.
1904. Crossley, T. Linsey, c/o Nashua River Paper Co., East Pepperell, Mass., U.S.A., Analytical Chemist.
1908. Crossley, Watson, c/o The Aluminium Corporation, Ltd., Wallsend-on-Tyne, Works Chemist.
1892. Crossman, Tom, Albion Brewery, Coldhurst Street, Oldham, Brewing Chemist.
1908. Croston, Henry, 178, Eckford Street, Greenpoint, Brooklyn, N.Y., U.S.A., Foreman.
1894. Crow, Henry W., 94, Romford Road, Stratford, E., Tar Distiller.
1884. Crow, Dr. J. K., Ivydene, Westcombe Park Road, Blackheath, S.E., Technical Chemist.
1893. Crowther, Edw., 20, Brookfield Place, Headingley, Leeds, Dyer.
1883. Crowther, Horace W., The Beeches, West Bromwich, Technical Chemist.
1906. Crowther, R. E., c/o Mark Fletcher and Sons, Ltd., Moss Lane, Whitefield, Manchester, Chemist.
1884. Crowther, Walter M., Chemical Works, Gomersal, near Leeds, Manufacturing Chemist.
1884. Crumie, W. D., 146, Washington Street, East Orange, N.J., U.S.A., Analytical Chemist.
1906. Cruser, Dr. Fred. Van D., c/o Union Metallic Cartridge Co., Bridgeport, Conn., U.S.A., Chemical Engineer.
1902. Crush, E. H., Talara, Peru, South America, Technical Chemist.
1892. Cullen, Wm., c/o South African Explosives Co., Ltd., Modderfontein, Transvaal, Chemist.
1903. Cullen, W. H., The Castner-Kellner Alkali Co., Ltd., Wallsend-on-Tyne, Engineer.
1897. Culmann, Dr. Julius, 116, Vanderbilt Avenue, Stapleton, Staten Is., N.Y., U.S.A., Chemist and Colourist.
1905. Culver, Ralph F., Box 162, Norwood, Mass., U.S.A., Chemist.
1883. Cumming, James, jun., Chemical Works, Yarraville, Melbourne, Australia, Chemical and Fertiliser Manufacturer.
1905. Cumming, R. Burns, Adelaide Chemical and Fertiliser Co., Ltd., Currie Street, Adelaide, South Australia, Manufacturing Chemist.
1897. Cunliffe, Albert J., Claytonfield, Clayton-le-Woods, Chorley, Lancashire, Calico Printer.
1907. Cunningham, James E., Minas Peña del Hierro, Provincia de Huelva, Spain, Analytical Chemist.
- O.M. Curphey, W. S., 7, Derby Crescent, Kelvinside, Glasgow, Alkali Works Inspector.
1898. Curtis, Marvin, 108, Front Street, San Francisco, Cal., U.S.A., Wine Chemist.
1903. Cushing, Robt. P., c/o Kistler, Lesh, & Co., Lock Haven, Pa., U.S.A., Chemist.
1902. Cutbush, Chas. G., 149, Westcombe Hill, Blackheath, S.E., Electrical Engineer.
1899. Cutler, Fred. F., 183, Essex Street, Boston, Mass., U.S.A., Publisher.
1904. Cutts, Henry E., c/o Stillwell and Gladding, 181, Front Street, New York City, U.S.A., Technical Chemist.
1906. Dains, F. B., Washburn College, Topeka, Kas., U.S.A., Professor of Chemistry.
1897. Dains, Herbert H., c/o J. E. Ferguson, 2, Union Court, London, E.C., Analytical Chemist.
1908. Dale, H. Gordon, Belmore, New Barnet, Herts., Analytical Chemist.
1907. Dalley, Henry, 9, East 69th Street, New York City, U.S.A., President.
1908. Dalton, Leonard V., 10, Dewhurst Road, West Kensington, W., Geologist (Petroleum).
1905. Dampney, Gerald F., Hunter's Hill, Sydney, N.S.W., Australia, Paint Manufacturer.
1908. Dance, Edward L., 51, Hotspur Street, Tynemouth, Northumberland, Chemist.
1884. Daniell, Louis C., (Journals) Royal Standard Brewery, Tamworth, New South Wales; and (snbs.) c/o W. T. Allen and Co., 132, Queen Victoria Street, London, E.C., Brewer.
1904. Danker, Dan. J., 247, Atlantic Avenue, Boston, Mass., U.S.A., Dye-stuff and Chemical Merchant.
1905. Danker, Fred. E., 73, Sawyer Avenue, Dorchester, Mass., U.S.A., Salesman (Oakes Manufacturing Co.).
1903. Dannenbaum, Dr. H., c/o National Ammonia Co., Frankford, Philadelphia, Pa., U.S.A., Secretary and Treasurer.
1885. Darby, Jno. H., Manor House, Brigg, Lincolnshire, Ironmaster.
- O.M. Darling, W. H., 26, Dover Street, Manchester, Analytical Chemist.
1887. Davenport, Dr. B. F., 161, Tremont Street, Boston, Mass., U.S.A., Consulting Chemist.
1900. Davidson, Alex., jun., 173, Colinton Road, Edinburgh, Analytical Chemist.
1899. Davidson, Charles, 65, Cadder Street, Pollokshields, Glasgow, Analytical Chemist.
1901. Davidson, G. M., Chicago and N.W. Railroad Shops, P.O. Station E., Chicago, Ill., U.S.A., Chemist.
1883. Davidson, J. E., 40, Percy Gardens, Tynemouth, Chemical Manufacturer.
1891. Davidson, Richard, 133, Victoria Road, Dundee, Oil Merchant's Clerk.
- O.M. Davidson, R. Holden, c/o United Alkali Co., Ltd., Annumonia Soda Works, Fleetwood, Manager.
1904. Davidson, Robert, c/o Dalgety and Co., Ltd., 15, Bent Street, Sydney, N.S.W., Australia.
1905. Davidson, Dr. Wm. B., City Gas Works, Saltley, Birmingham, Chemist.
1889. Davies, G. W., 8, Spring Hill, Stockport, Chemical Lecturer.
1906. Davies, Harry R., 58, Hamilton Street, Roadville, Mass., U.S.A., Chemist.
1898. Davies, Herbert E., The Laboratory, 28, Chapel Street, Liverpool, Analytical Chemist.
1907. Davies, James, 221, Malpas Road, Brockley, London, S.E., Scientific Apparatus Maker.
1896. Davies, Llewellyn J., 103, Bute Road, Cardiff, Analytical and Consulting Chemist.
1886. Davies, M. Lloyd, North American Chemical Co., Bay City, Mich., U.S.A., Alkali Works Manager.
1897. Davies, Saml. H., c/o Rowntree and Co., Ltd., Cocoa Works, York, Research Chemist.
1903. Davies, Thomas, 56, Wellesley Street, Toronto, Ont., Canada, Manufacturer.
1908. Davies, T. H., c/o John Cox and Co.'s Successors, Stillhouse Lane, Bedminster, Bristol, Tanner.
- O.M. Davis, A. R., Fern Bank, Hawarden, Flintshire, Analytical Chemist.
1901. Davis, Bernard F., c/o H. F. Collins, Cerro Muriano, Cordoba, Spain, Metallurgical Engineer.
1902. Davis, Charles B., c/o National Brewers' Academy, 402, West 23rd Street, New York City, U.S.A., Technical Chemist.
1902. Davis, Emerson, 39, Watson Street, Detroit, Mich., U.S.A., Chemist.
1893. Davis, Fred., 51, Imperial Buildings, Ludgate Circus, London, E.C., Consulting Chemist.
1908. Davis, G. Keville, 265, Strand, London, W.C., Chemical Engineer.

D

- O.M. Dacie, J. C., Soap Works, Putney, S.W., Soap Manufacturer.
1907. Daggett, W. W., c/o New Jersey Zinc Co., 71, Broadway, New York City, U.S.A., Chemical Engineer.

- O.M. Davis, H. W., Government Laboratory, Clement's Inn Passage, Strand, W.C., Analytical Chemist.
1907. Davis, Robt. W., jun., c/o E. I. du Pont de Nemours Powder Co., Haskell, N.J., U.S.A., Chemist.
1906. Davis, V. P., 31, Union Square West, New York City, U.S.A., Chemist.
1897. Davis, Wm. A., 2, Ashgrove Road, Bromley Road, Catford, S.E., Chemist.
1900. Daw, Fred W., Daffryn House, Ebbw Vale, Mon., Metallurgical Chemist.
1908. Daw, Hilder, 790, City Hall Avenue, Montreal, P.Q., Canada, Civil Engineer.
1903. Daves, Arthur W., 3, Madison Place, Albany, N.Y., U.S.A., Chemist.
- O.M. Dawson, C. A., 32, Elm Hall Drive, Mossley Hill, Liverpool, Technical Chemist.
1886. Dawson, W. Haywood, British Alizarin Co., Ltd., Silvertown, E., and (Journals), 15, Wrotesley Road, Woolwich, S.E., Technical Chemist.
1901. Day, Dr. David T., U.S. Geological Survey, Washington, D.C., U.S.A., Geologist.
- O.M. Deacon, H. Wade, 8, Ullet Road, Liverpool; and (Journals) c/o F. W. Wright, 22, Peel House Lane, Widnes, Alkali Manufacturer.
- O.M. Deakin, H. T., Dewhurst, Egerton, near Bolton, Dyer.
1903. Dean, Harry, 23, Spinkfield Road, Birkby, Huddersfield, Chemist.
1906. Dean, Harry, Armstrong College, Newcastle-on-Tyne, Demonstrator.
1899. Deane, Leopold M., 21, Station Terrace, Abbey Village, near Chorley, Lancs., Explosives Chemist.
1905. Dearman, E., c/o The Lavers Manufacturing Co., Ltd., Woolwich, N.S.W., Australia, Tar Distiller.
1892. Deaville, B., Beech Avenue, Nottingham, Manufacturing Chemist.
1908. Deavitt, Henry M., 56, Fifth Avenue, Chicago, Ill., U.S.A., Analytical and Consulting Chemist.
1899. De Castro, J. Paul, Laboratory, Ellingham House, Arundel Street, Strand, W.C., Consulting Chemist and Assayer.
1902. De Cew, J. A., 14, Sun Life Building, Montreal, Canada, Chemist.
1893. De Clerck, Maurice, Henle-Jez-Courtrai, Belgium.
1884. Deering, W. H., 3, Broad Park Avenue, Ilfracombe, N. Devon, Analytical Chemist.
1900. Deerr, Noel F., Experiment Station, Hawaiian Sugar Planters' Association, Honolulu, H.I., U.S.A., Analytical Chemist.
1902. Deghée, Dr. Jos. A., 247, Harrison Street, Brooklyn, N.Y., U.S.A., Chemist.
1901. De Jonge, Cornelius, 36, Doughty Street, Brooklyn, N.Y., U.S.A., Pharmaceutical Chemist.
1893. Delahaye, Philibert, 105, Rue St. Lazare, Paris (IX.), Gas Engineer.
1908. Delaney, Chas. R., 63, Guncher Building, Baltimore, Md., U.S.A., Chemical Engineer.
1904. Delany, Chas., c/o Elliott Bros., Ltd., O'Connell Street, Sydney, N.S.W., Australia, Chemist.
1908. Dellschaft, Dr. F. H., Winton, Northwich, Cheshire, Manufacturing Chemist.
1888. Dempsey, Geo. C., 165, Market Street, Lowell, Mass., U.S.A., Chemist.
1904. Dempwolf, Chas., jun., 713, South George Street, York, Pa., U.S.A., Chemical Manufacturer.
1907. Demuth, Rudolf, 200, Worth Street, New York City, U.S.A., Chemist.
1909. Demuth, Rudolph, 31 32, Budge Row, Cannon Street, London, E.C., Manufacturer.
1899. Denham, Wm. S., 2, Kelvinside Terrace North, Glasgow, Chemist.
1891. Denison, Joseph R., c/o Denison, Preussner and Co., Valley Dyeworks, Bradford, Yorks., Analytical Chemist.
1908. Dennis, Martin, 859, Summer Avenue, Newark, N.J., U.S.A., Manufacturing Chemist.
1907. Dennison, Henry S., South Framingham, Mass., U.S.A., Manufacturer.
1898. Dent, Dr. Frankland, Government Analyst's Dept., Singapore, S.S., Government Analyst.
1905. Derby, Wallace G., c/o Nichols Copper Co., Laurel Hill, New York City, U.S.A., Assayer.
1901. Devas, Dr. Ernest W., Fairview, Hale Grove, Edgware, N.W., Technical Chemist.
1906. Deverell, Louis C., c/o Straits Trading Co., Ltd., Singapore, S.S., Chief Chemist.
1908. Dew, Joseph A., Woodside, Windsor Road, Wanstead, Essex, Varnish Manufacturer.
1898. Dewar, Alex. H., c/o The Linoleum Manufacturing Co., Staines, Middlesex, Chemist.
- O.M. Dewar, Sir J., F.R.S., Royal Institution, Albemarle Street, W. (Journals); and 1, Scroope Terrace, Cambridge, Professor of Chemistry and Physics.
1889. Dewey, Fred. P., Lanier Heights, Washington, D.C., U.S.A., Metallurgist.
1904. Dewhurst, J. A., Borough Laboratory, Halifax, Yorks., Analyst.
1891. De Wilde, Prof. P., 1, Quai du Léman, Geneva, Switzerland, Professor of Chemistry.
1903. Diamond, Wm., c/o John Bowes and Partners, Ltd., Marley Hill Colliery, Swalwell, R.S.O., Durham, Works Manager.
- O.M. Dibdin, W. J., 2, Edinburgh Mansions, Howick Place, S.W., Analytical Chemist.
1897. Dick, Jno., c/o Jno. Dick, Ltd., 77, York Street, Toronto, Ont., Canada, Manufacturer.
1902. Dick, Jno., Wharf Road, Cubitt Town, London, E., Manager and Chemist.
1904. Dick, W. D., c/o Hugh Baird and Sons, 29, St. Vincent Place, Glasgow, Analytical Chemist.
1898. Dickenson, F. M., c/o Broken Hill Proprietary Co., 3, Great Winchester Street, London, E.C., Secretary.
1904. Dickenson-Gair, C. J., *See under Gair*.
1909. Dickerman, Alton L., Room 1110, 5, Nassau Street, New York City, U.S.A., Coal Merchant.
1902. Dickerman, Prof. Judson C., 1110, Mound Street, Madison, Wis., U.S.A., Chemical Engineer.
1893. Dickerson, E. N., 141, Broadway, New York City, U.S.A., Lawyer.
- O.M. Dickinson, A. J., 57, Lewisham High Road, New Cross, S.E., Tar Distiller.
1905. Dickinson, Cyril, Southwark Town Hall, Walworth Road, London, S.E., Analytical Chemist.
1898. Dickson, Samuel, 2, Broadway, Westminster, S.W., Analytical Chemist.
1899. Dieckmann, Dr. Otto, 1182, Harrison Avenue, Cincinnati, Ohio, U.S.A., Chemist.
1901. Diehl, Oscar C., c/o Saginaw Salt Co., St. Charles, Mich., U.S.A., Chemist.
1908. Diekman, Dr. George C., 115, West 68th Street, New York City, U.S.A., Professor of Pharmacy.
1907. Dielman, Louis H., 106, West Mulberry Street, Baltimore, Md., U.S.A., Pharmaceutical Chemist.
1894. Diestel, Wm., 117, Hudson Street, New York City, U.S.A., Dyestuff Importer.
1908. Dill, Colby, Perth Amboy, N.J., U.S.A., Chemist.
1906. Dillon, Fred. N., 16, Prospect Street, Fitchburg, Mass., U.S.A., Engineer.
1898. Dillon, Wm., Highfield, Wetherby, Yorks, Oil, Colour, and Varnish Manufacturer.
- O.M. Divers, Dr. E., F.R.S., 3, Canning Place, Palace Gate, Kensington, W., Professor of Chemistry.
1903. Divine, Robt. E., c/o Baker and Adamson Chemical Co., Easton, Pa., U.S.A., Chemist.
1899. Dixon, Fred W., 557, West 144th Street, New York City, U.S.A., Dyer.
1888. Dixon, Prof. Harold B., F.R.S., Owens' College, Manchester, Professor of Chemistry.
1884. Dixon, Wm., 102, Spring Street, Bury, Lancashire, Science Master.
1902. Dixon, Wm. A., 97, Pitt Street, Sydney, N.S.W., Australia, Public Analyst and Assayer.
1892. Dobb, Thos., c/o J. T. Dobb and Son, West Bar, Sheffield, Pharmaceutical Chemist.
- O.M. Dobbie, Dr. J. J., F.R.S., Royal Scottish Museum, Chambers Street, Edinburgh, Director.
- O.M. Dobbin, Dr. L., Chemical Laboratory, University, Edinburgh, Professor of Chemistry.

1908. Dobbs, Ernest J., 125, St. Asaph Road, Brockley, London, S.E., Analytical Chemist.
1906. Dobson, Samuel, 5, Bank Buildings, Wanstead, N.E., Paint Works Manager.
1907. Dodd, Arthur, Lyndhurst, Woolwich Road, Belvedere, Kent, Assistant Works Manager.
1890. Dodd, A. J., Heathfield House, Belvedere, Kent, Works Manager.
1889. Dodd, W., Ralph, Trederwen, Village Road, Enfield, Middlesex, Chemical Works Manager.
1906. Dodds, Thos., c/o Reckitt & Sons, Ltd., and (Journals) 7, The Oval, The Garden Village, Hull, Works Manager and Chemist.
1900. Dodge, Dr. Francis D., 291, Henry Street, Brooklyn, N.Y., U.S.A., Chemist.
1907. Dodge, Frank E., c/o Art Fibre Co., Norristown, Pa., U.S.A., Chemist.
1906. Dodsworth, Walter A., Journal of Commerce, 32, Broadway, New York City, U.S.A., Editor.
1897. Doerflinger, Wm. F., 52, Beaver Street, New York City, U.S.A., Research Chemist.
1908. Doherty, Robert E., 242, Newberry Avenue, Chicago, Ill., U.S.A., Chemist.
1897. Dohme, Dr. Alf. R. L., Messrs. Sharp and Dohme, Baltimore, Md., U.S.A., Manufacturing Chemist.
1905. Dolan, H., Dunesk, Grappenhall Road, Stockton Heath, Warrington, Chemist.
1897. Dolge, Carl B., Westport, Conn., U.S.A., Manufacturer of Instruments and Antiseptics.
1903. Donald, Dr. Jas. T., 112, St. Francois Xavier Street, Montreal, Canada, Consulting Chemist.
1906. Donald, Richard A., 16, King Street West, Toronto, Canada, Wood Distiller.
- O.M. Donald, W., Saltecoats, N.B., Analytical Chemist.
1900. Donald, Wm., Ridgefield Park, Bergen Co., N.J., U.S.A., Assayer and Chemist.
1902. Donaldson, Thos., c/o South African Explosives Co., Ltd., Modderfontein, Transvaal, Chemist.
1905. Donnan, Prof. F. G., Muspratt Laboratory, The University, Liverpool, Professor of Physical Chemistry.
1886. Doolittle, Orrin S., 476, Warburton Avenue, Yonkers, N.Y., U.S.A., Chemist.
1905. Doolittle, Roscoe E., 109, Hillside Avenue, Glen Ridge, N.J., U.S.A., Chemist.
1890. Dore, Jas., Copper Works, High Street, Bromley-by-Bow, E., Distiller's Engineer.
1896. Doremus, Dr. Chas. A., 55, West 53rd Street, New York City, U.S.A., Professor of Chemistry.
- O.M. Dott, D. B., 10, Abbey Mount, Edinburgh, Analytical Chemist.
1897. Douglas, Geo., Farfield Hall, Addingham, Yorks., Dyer.
1894. Douglas, London M., 3, Lauder Road, Edinburgh, Chemical Manufacturer.
1909. Douglas, Robt. P., 18, Russell Street, Bolton, Chemist.
1884. Douglas, William, Diamond Plantation, Demerara, British Guiana, Chemical Engineer.
1900. Doulton, H. Lewis, Royal Doulton Potteries, Lambeth, S.E., Potter.
1906. Dow, Allan W., 24, East 21st Street, New York City, U.S.A., Chemical Engineer.
1898. Dow, Herbert H., Midland, Mich., U.S.A., Manufacturing Chemist.
1908. Dow, John W., 564, Park Avenue West, Mansfield, Ohio, U.S.A., Manufacturing Chemist.
1905. Dowbiggin, James, Craiglands, Albert Park, Lancaster, Chemist.
1907. Downing, Richard, jun., East Norwich, Long Island, N.Y., U.S.A.
1885. Dowson, J. Emerson, 39, Victoria Street, Westminster, S.W., Civil Engineer.
1901. Doxrud, Christian, Technical School, Christiania, Norway, Professor of Chemical Technology.
1907. Doyle, B. W., 11, Pine Street, Leominster, Mass., U.S.A., Manufacturer.
1902. Drake, Bryant S., 1121, Eighth Avenue, Oakland, Cal., U.S.A., Chemist.
1885. Drake, Chas. A., Three Mills Distillery, Bromley-by-Bow, E., Brewer.
1886. Dreaper, W. P., 68, Victoria Street, Westminster, S.W., Consulting Chemist.
1907. Dreyerhoff, Max, Dresden, Saxony, Filter-paper Maker.
- O.M. Drew, D., Lower House Print Works, near Burnley, Calico Printer.
1906. Drew, W. Newton, Raincliffe, Ecclesfield, near Sheffield, Chemical Manufacturer.
1896. Drewsen, Dr. Viggo B., 5, Beekman Street, New York City, U.S.A., Wood Pulp and Paper Expert.
1909. Dreydel, Alfred J., Lamp Department Laboratory, The Edison Swan U.E.L. Co., Ltd., Ponders End, Middlesex, Works Chemist.
- O.M. Dreyfus, Dr. C., Clayton Aniline Co., Ltd., Clayton, Manchester, Dye Manufacturer.
1905. Dreyfus, Dr. Isaac, c/o Schoellkopf & Co., Perry and Mississippi Streets, Buffalo, N.Y., U.S.A., Chief Chemist.
1904. Dreyfus, Dr. L. A., c/o The Muralo Co., New Brighton, N.Y., U.S.A., Chemist.
1893. Dreyfus, S., 1, Sunnyside Terrace, North Road, Clayton, Manchester, Chemist.
1899. Dreyfus, Dr. Wm., 57, East 96th Street, New York City, U.S.A., Chemist.
1899. Drobegg, G., 81, Maiden Lane, New York City, U.S.A., Superintending Chemist.
1889. Drummond, Hon. Sir George, K.C.M.G., 80, St. Francois Xavier Street, Montreal, Canada.
1898. Drummond, Dr. Isaac W., 436, West 22nd Street, New York City, U.S.A., Chemist.
1903. Dubuque, Edwin D., 416, Dillaye Building, Syracuse, N.Y., U.S.A., Chemist.
1899. Ducas, B. P., 151, Front Street, New York City, U.S.A., Chemical and Dyestuff Importer.
1907. Duca, Dr. Wilhelm, 41, Atlantic Street, Hackensack, N.J., U.S.A., Chemist.
1905. Duché, E., 6, Eastcheap, London, E.C., Merchant.
1909. Duchemin, René P., 6, Rue Chanoinesse, Paris IV., France, Chemical Engineer.
1897. Duckham, Alex., Phoenix Wharf, West Ferry Road, Millwall, E., Works Chemist.
1908. Duckworth, G. F., Trout Mills, North Bay, Ont., Canada, Works Manager.
1905. Duckworth, Harry S., Hamilton Printworks, Lowell, Mass., U.S.A., Printworks Chemist.
1890. Dudley, Dr. C. B., 1219, 12th Avenue, Altoona, Pa., U.S.A., Analytical Chemist.
1887. Dudley, Prof. W. L., Vanderbilt University, Nashville, Tenn., U.S.A., Professor of Chemistry.
1899. Duff, Wm. S., Merrie Lands, Westbury Road, Buckhurst Hill, Essex, Manufacturing Chemist.
1905. Duffus, W. B., Las Minas de Rio Tinto, Prov. de Huelva, Spain, Chemist.
1901. Dufty, Lawrence, 119, Rustlings Road, Sheffield, Analytical Chemist.
1905. Duggan, Edw. J., The Charles E. Sholes Co., 164, Front Street, New York City, U.S.A., Vice-President.
- O.M. Duggan, T. R., 60, Foyle Road, Blackheath, S.E., Analytical Chemist.
1898. Duisberg, Dr. Carl, The Bayer Co., Ltd., (Journals) Elberfeld, Germany; (subscriptions) 19, St. Dunstan's Hill, London, E.C., Chemist.
1905. Dukes, Bernhard, 1, Great James Street, Bedford Row, London, W.C., Patent Agent.
1888. Dukes, T. William, Box 10, Vryheid, South Africa, Merchant.
1906. Dunnealfe, Roger, Forge Mills, Bestwood Colliery, Nottingham, Glue Manufacturer.
1889. Duncan, Arthur W., 1, Trafalgar Road, Higher Bentcliffe, Pendleton, Manchester, Analytical Chemist.
1904. Duncan, Robert A., P.O. Box 500, Honolulu, Hawaii, Chemist.
1908. Duncan, Prof. Robert Kennedy, University of Kansas, Lawrence, Kansas, U.S.A., Prof. of Industrial Chemistry.
1906. Dunford, Jno. H., Trent Side Bone Works, Nottingham, Assistant Manager.

1898. Dunham, Dr. E. K., 35, East 68th Street, New York City, U.S.A., Professor of Bacteriology and Hygiene.
1905. Dunlop, Harry, c/o R. R. Tatlock & Thomson, 156, Bath Street, Glasgow, Chemist.
1892. Dunn, Fred., 193, Collins Street, Melbourne, Victoria, Australia, Analytical Chemist.
- O.M. Dunn, Dr. J. T., 10, Dean Street, Newcastle-on-Tyne, Consulting Chemist.
- O.M. Dunn, P., Northern Assurance Buildings, Albert Square, Manchester, Chemical Merchant.
1908. Dünscmann, Dr. Max, c/o Meister, Lucius, und Brüning, Ellesmere Port, Cheshire, Manager.
1901. Dunsford, Geo., Laboratory, Wigan Coal and Iron Co., Ltd., Wigan, Analytical Chemist.
1907. Dunstan, A. E., Technical College, East Ham, E., Head of Chemical Department.
1907. Dupré, F. H., 2, Edinburgh Mansions, Howick Place, S.W., Analytical Chemist.
1907. Dupré, P. V., 2, Edinburgh Mansions, Howick Place, S.W., Analytical Chemist.
1897. Durant, H. T., 108, Olive Road, Cricklewood, N.W., Metallurgist.
1905. Durfee, Winthrop C., 516, Atlantic Avenue, Boston, Mass., U.S.A., Manufacturing Chemist.
1897. Durkee, Frank W., Tufts College, Medford, Mass., U.S.A., Professor of Chemistry.
1907. Durrans, Thos. H., 1, Cornwall Terrace, Regent's Park, London, N.W., Chemist.
1899. Duryea, Chester B., c/o Edwardsburg Starch Co., Cardinal, Ont., Canada, Starch Manufacturer.
1906. Dushman, Saul, Faculty of Applied Science, University of Toronto, Canada, Electrochemist.
1891. Dyorkovitz, Dr. P., 45, St. Mary Axe, London, E.C., Technical Chemist.
1903. Dyck, George E., 2022, West 38th Street, Chicago, Ill., U.S.A., Analytical Chemist.
- O.M. Dyer, Dr. B., 17, Great Tower Street, London, E.C., Analytical and Consulting Chemist.
1907. Dyes, Dr. W. A., 18, Exchange Street, Manchester, Seller of Patents and Processes.
- O.M. Dyson, C. E., Flint, North Wales.
1902. Dyson, George W., 89, Cowlishaw Road, Sheffield, Analyst.
1892. Dyson, Septimus, 44, Fairmile Avenue, Streatham, S.W., Manufacturing Chemist.
- E**
1909. Eachus, Charles, 323, Academy Street, Newark, N.J., U.S.A., Leather Trade Chemist.
1905. Eager, Chas. E., 77, Pearl Street, Boston, Mass., U.S.A., Merchant.
1904. Eames, Charles J., 99, Water Street, New York City, U.S.A., Consulting Chemist.
1899. Eamshaw, Edward H., 763, Broad Street, Newark, N.J., U.S.A., Chemist.
- O.M. Earp, W. R., Preston Brook, near Warrington, Chemical Manufacturer.
1884. Eastick, C. E., 7, King Edward Street, Whitechapel, E., Sugar Works Manager.
- O.M. Eastick, J. J., Ashburton, Northfield Road, Stamford Hill, N., Analytical and Consulting Chemist.
1890. Eastlake, A. W., Grosmont, Palace Road, Streatham Hill, S.W., Petroleum Works Manager.
1885. Eastwood, Edw., 7, Bolton Road, Port Sunlight, Birkenhead, Soapmaker.
1902. Eastwood, Robert F., 90, Peel House Lane, Widnes, Chemist.
1906. Eaton, B. J., Institute of Medical Research, Kuala Lumpur, Selangor, Fed. Malay States, Government Chemist.
1903. Eaton, Edward N., Room 1240, 334, Dearborn Street, Chicago, Ill., U.S.A., Chemist.
1902. Eckel, Edwin Clarence, 209, Munsey Building, Washington, D.C., U.S.A., Geologist.
1907. Eckenstein, Thos. C., 19, Huskisson Street, Liverpool, Analytical Chemist.
1892. Eddy, Harrison P., Sewage Purification Works, Worcester, Mass., U.S.A., Superintendent.
1901. Eddy, W. Clifton, 55, High Street, Woodbury, N.J., U.S.A., Chemist.
1885. Edge, Anthony, 79, Milton Street, Readville, Mass., U.S.A., Chemist.
1909. Edge, J. Harold, "Great Marld," Smithills, Bolton, Lancashire, Technical Chemist.
1902. Edison, Thos. Alva, Edison Laboratory, Orange, N.J., U.S.A., Inventor and Manufacturer.
1908. Edmunds, Wm. T., Church Road, Burry Port, Carmarthenshire, Assayer.
1909. Edwards, George M., 241, Pine Avenue West, Montreal, Canada, Paintworks Manager.
1902. Edwards, H. Seaton, 19, Park Road, Port Sunlight, Cheshire, Analyst.
1906. Egleson, J. E., Capelton, Quebec, Canada, Chemist.
1895. Ehrenfeld, Prof. Chas. H., York Collegiate Institute, York, Pa., U.S.A., Professor of Chemistry.
1896. Ehrhardt, Ernest F., Badische Anilin und Soda Fabrik, Ludwigshafen a/Rhein, Germany, Research Chemist.
1895. Ekenberg, Dr. M., Fairlawn, Clarence Road, Clapham Park, S.W., Technical Chemist.
1885. Elborough, T., 59, Mark Lane, London, E.C., Manure Manufacturer.
1901. Elkan, Leo A., 594, Dearborn Avenue, Chicago, Ill., U.S.A., Tanner.
1901. Elkins, Arthur W., 520, Park Avenue, East Orange, N.J., U.S.A., Civil Engineer.
1884. Elliott, Dr. A. H., Consolidated Gas Co., 4, Irving Place, New York City, U.S.A., Chemist.
1907. Elliott, George K., c/o Lankenheimer Co., Cincinnati, Ohio, U.S.A., Chief Chemist.
1896. Elliott, Dr. J. F., c/o Grimwade and Co., 6, Trinity Square, E.C.; and (Journals), O'Connell Street, Sydney, N.S.W., Manufacturing Chemist.
1902. Elliott, Victor G., Chemical Works, Rozelle, Sydney, N.S.W., Australia, Manufacturing Chemist.
1906. Ellis, Arthur E., 317, West 56th Street, New York City, U.S.A., Chemist.
1905. Ellis, Carleton, Hommock Road, Larchmont, N.Y., U.S.A., Chemical Engineer.
1885. Ellis, C. J., Almorah Villa, Milngavie, near Glasgow, Technical Chemist.
1893. Ellis, E. Victor, 7, Hillside Crescent, Edinburgh, Analytical Chemist.
1894. Ellis, C. Beloe, 70, Chancery Lane, London, W.C., Patent Agent.
- O.M. Ellis, H., 120, Regent Road, Leicester, Chemical Merchant.
1907. Ellis, Theodore H., East Brooklyn Station, Baltimore, Md., U.S.A., Oil Refiner.
1891. Ellis, Prof. W. Hodgson, 74, St. Alban Street, Toronto, Ont., Canada, Professor of Applied Chemistry.
1891. Ellison, Henry, Northfield, Cleckheaton, Yorks, Manufacturing Chemist.
- O.M. Elmore, A. S., 72, Gloucester Terrace, Hyde Park, London, W., Electro-Metallurgist.
1907. Elms, Jas. W., c/o E. I. du Pont de Nemours Powder Co., Haskell, N.J., U.S.A., Chemist.
1907. Elsdon, A. Vincent, 88, Ellicombe Road, Charlton, S.E., Analytical Chemist.
1904. Elson, J. Hugh, Monroe Drug Co., Quincy, Ill., U.S.A., General Manager.
1902. Emery, Arthur L., c/o Smith, Emery and Co., 651, Howard Street, San Francisco, Cal., U.S.A., Chemical Engineer.
1899. Emery, E. G., Pinole, Contra Costa Co., Cal., U.S.A., Technical Chemist and Engineer.
1907. Emmons, Frank W., c/o Washburn Crosby Co., Minneapolis, Minn., U.S.A., Chemist.
1907. Enrich, Horace H., Perth Amboy Plant, Am. S. and R. Co., Manser, N.J., U.S.A., Mining Engineer.
1907. Emslie, B. Leslie, 1102-1105, Temple Building, Toronto, Canada, Agricultural Chemist.
1897. Enequist, Erik W., 1651, New York Avenue, Brooklyn, N.Y., U.S.A., Chemist.

1894. Enequist, John, 3710, Avenue J., Brooklyn, N.Y., U.S.A., Chemical Engineer.
1904. Englehard, Charles, 32, Cortlandt Street, New York City, U.S.A., Platinum Importer.
1895. English, Frank H., 47, Shelley Avenue, East Ham, E., Analytical Chemist.
1899. Enright, Bernard, 625, West Lexington Avenue, Independence, Mo., U.S.A., Chemist.
1906. Ephraim, Dr. Julius, Königgrätzerstrasse 69, Berlin, S.W. II, Germany, Chemist and Patent Agent.
1904. Erdmann, Prof. Dr. H., Bismarck Strasse 110, Charlottenburg, Berlin, Professor of Inorganic Chemistry.
1907. Erdoes, Julius, 242, East 122nd Street, New York City, U.S.A., Chemical Engineer.
1902. Erhart, Wm. H., 81, Maiden Lane, New York City, U.S.A., Manufacturing Chemist.
1907. Eriesson, A. D., Grafton, Ill., U.S.A., Chemist.
1904. Ermen, Walter F. A., 10, Marsden Street, Manchester, Analytical Chemist.
1905. Ernst, C. A., Lansdowne, Pa., U.S.A., Chemist.
1909. Erpf, V. P., Room 1103, Temple Building, Toronto, Canada, Manager (Nitrate Agencies Co.).
1888. Erskine, J. K., P.O. Box 88, Benoni, Transvaal, Analytical Chemist.
1897. Escher, Paul, 1319, Pearl Street, Alameda, Cal., U.S.A., Chemist.
1884. Esilman, A., 25, Roe Lane, Southport, Lancashire, Analytical Chemist.
- O.M. Esteourt, C., 5, Seymour Grove, Old Trafford, Manchester, Consulting Chemist.
1905. Etheridge, Arthur T., 85, Hampton Road, Birchfields, Birmingham, Chemist.
1903. Euler, C. G., 18-20, Platt Street, New York City, U.S.A., Agent for Essential Oils.
1883. Evans, Enoch, 660, Coventry Road, Birmingham, Accountant.
1903. Evans, F. Sparke, Avonside Tannery, Bristol, Tanner.
1905. Evans, Geo. A., 832, Yonge Street, Toronto, Canada, Pharmacist.
1905. Evans, Jacob V. R., Ridgway, Pa., U.S.A., Chemist.
1904. Evans, Jas. Rittenhouse, 3, High Street, Pottstown, Pa., U.S.A., Chemist.
1905. Evans, John, 67, Surrey Street, Sheffield, Analytical Chemist.
1908. Evans, Prof. Nevil Norton, Redpath Museum, McGill University, Montreal, Canada, Associate Professor of Chemistry.
1889. Evans, R. E., 3, Glencoe, Stratford-on-Avon, Brewing Chemist.
1909. Evans, S. Marshall, 100, William Street, New York City, U.S.A., Sublimed White Lead Manufacturer.
1903. Evans, Wm. J., 91, Fulton Street, New York City, U.S.A., Manufacturing Chemist.
1898. Evans, Wm. Percival, Canterbury College, Christchurch, New Zealand, Professor of Chemistry.
1904. Everitt, Walter, Norwood Wharf, Southall, Middlesex, Analyst.
- O.M. Evershed, F., c/o Clarke, Nickolls, and Coombs, Hackney Wick, N.E., Chemist.
1907. Eves, Archie P., 762, East Buchtel Avenue, Akron, Ohio, U.S.A., Chemist.
1894. Ewan, Dr. Thos., c/o Cassel Cyanide Co., Shuna Street, Maryhill, Glasgow, Chemist.
1904. Ewing, Dr. A. Ramsay, 2, York Terrace, Shettleston, Glasgow, Technical Chemist.
1905. Eynon, Lewis, 57, Darent Road, Stamford Hill, N., Chief Chemist (London Beetroot Sugar Association).
1902. Fahrig, Dr. Ernst, 3642, Old York Road, Philadelphia, Pa., U.S.A., Consulting Chemical Engineer.
1902. Faill, Jas., 51, Partickhill Road, Glasgow, Technical Chemist.
1902. Fairchild, Benj. T., P.O. Box 1120, New York City, U.S.A., Manufacturing Chemist.
1903. Fairhall, E. J., 96, Blackstock Road, Finsbury Park, N., Chemist.
- O.M. Fairley, T., 17, East Parade, and (Communications) 8, Newton Grove, Leeds, Analytical Chemist.
1901. Fairlie, Jas., Camelon Chemical Works, Falkirk, N.B., Manufacturing Chemist.
1908. Fairweather, J. H., Laboratory, 19 and 20, Aldgate, London, E.C., Analytical Chemist.
1902. Fairweather, Wallace C., 65-66, Chancery Lane, London, W.C., Engineer.
1898. Falding, F. J., 55, Broadway, New York City, U.S.A., Chemical Engineer.
1908. Fales, Harold A., 308, Schermerhorn Street, Brooklyn, N.Y., U.S.A., Secretary (The W. N. Fales Co.).
1897. Farmer, John E., Bletsoe, New Road, Mitcham Junction, Surrey, Assistant Manager (Sewage Works).
- O.M. Farrant, N., c/o J. Nicholson and Sons, Chemical Works, Hunslet, Leeds, Chemist.
1897. Farrell, Frank J., 44, Prince of Wales Mansions, Battersea Park, S.W., Analytical Chemist.
- O.M. Farrington, T., 5, Summerhill Terrace, Cork, Ireland, Chemical Engineer.
1908. Favre, A., 21, Mincing Lane, London, E.C., Laboratory Furnisher.
1884. Fawsitt, C. A., Atlas Chemical Works, East Nelson Street, Glasgow, Chemical Manufacturer.
1903. Fawsitt, Dr. Chas. E., The University, Sydney, N.S.W., Australia, Prof. of Chemistry.
1906. Feeley, Edward J., 88, Broad Street, Boston, Mass., U.S.A., Aniline Colour Dealer.
1903. Feilmann, Dr. M. E., 92, Victoria Street, Westminster, S.W., Chemist.
1892. Feld, Walther, Hauptstrasse 14, Zehlendorf-Warmseebahn, Germany, Chemical Works Director.
1905. Felton, Herbert L., 524, East Second Street, South Boston, Mass., U.S.A., Distiller.
1900. Ferguson, Geo. A., 121, West 42nd Street, New York City, U.S.A., Professor of Analytical Chemistry.
- O.M. Ferguson, Prof. J., The University, Glasgow, Professor of Chemistry.
1896. Ferguson, J. Hart, Loch Katrine Distillery, Camlachie, Glasgow, Distillery Manager.
1907. Ferguson, Wm., 34, St. Peter Street, Montreal, Canada, Chemical Agent.
1902. Fergusson, Donald M., c/o Acadia Sugar Refining Co., Halifax, N.S., Canada, Analytical Chemist.
1883. Fergusson, H., Prince Regent's Wharf, Victoria Docks, E., Technical Chemist.
1908. Fernbach, Dr. R. Livingston, 97, Warren Street, New York City, U.S.A., Chemist.
1905. Fernberger, Harry M., 1939, North 12th Street, Philadelphia, Pa., U.S.A., Chemist.
1905. Fiebigler, Peter, 530, Canal Street, New York City, U.S.A., Colour Chemist.
1893. Fiebing, John H., 644, 28th Street, Milwaukee, Wis., U.S.A., Leather Trade Chemist.
1885. Field, E. W., Cloud House, Sandiacre, near Nottingham, Brewer.
1887. Field, S. S., 3, Glenhuce Road, Blackheath, S.E., Manufacturing Chemist.
1891. Field, Wm. Eddington, Martin Street, Elsternwick, Melbourne, Victoria, Chemist.
1900. Fillis, Frank, Brookland, London Road, Neath, South Wales, Cement Works Manager.
1907. Finch, Archibald M., Vitriol and Chemical Works, Cwmbran, R.S.O., Monmouthshire, Chemical Manufacturer.
1904. Finch, Martin L., Vitriol and Chemical Works, Cattedown, Plymouth, Chairman of Directors.

F

1907. Finch, Wm. J., c/o Dominion Tar and Chemical Co., Box 599, Sydney, N.S., Canada, Works Chemist.
1905. Findlay, Dr. Alex., The University, Birmingham. Lecturer on Physical Chemistry.
1899. Fingland, Jno. J., Saulton, B.C., Canada, Analytical Chemist.
1904. Finn, Cornelius P., Hemsworth Colliery, Hemsworth, near Wakefield, Yorks., Technical Chemist.
1903. Fischer, Dr. Carl, 213-215, Water Street, New York City, U.S.A., Chemist.
1903. Fish, Chas. C. R., 10, Park Square, Boston, Mass., U.S.A., Chemist.
1905. Fish, Chas. H., c/o B. B. and R. Knight, Providence, R.I., U.S.A., Textile Manufacturer.
1900. Fisher, Henry, 57, East 83rd Street, New York City, U.S.A., Teacher of Chemistry.
- O.M. Fisher, W. W., 5, St. Margaret's Road, Oxford, Chemical Lecturer.
1906. Fiske, Aug. H., 10, Buckingham Place, Cambridge, Mass., U.S.A., Chemist.
1895. Fison, Jno., Messrs. Jas. Fison and Sons, Thetford, Norfolk, Chemical Manufacturer.
1904. Fitch, A. J., 1, Summerlands Mansions, Muswell Hill, N., Brewer's Chemist.
1902. FitzGibbon, Thos., 115, Harbord Street, Fulham, S.W., Analytical Chemist.
1907. Fitzhardinge, R. B., Elliott Bros.' Chemical Works, Rozelle, Sydney, N.S.W., Analyst.
1900. Fitz-Randolph, R. B., State Laboratory of Hygiene, Trenton, N.J., U.S.A., Bacteriologist and Chemist.
1896. Flammer, E., c/o Kraemer and Flammer, Heilbronn a/N., Germany, Manufacturing Chemist.
1903. Fleming, Jno. A., 1757, Willard Street N.W., Washington, D.C., U.S.A., Engineer.
- O.M. Fletcher, A. E., Coombe Lea, Dorking, Surrey, Ex-Chief Inspector Alkali, &c., Works.
1893. Fletcher, E. Morley, 30, Grosvenor Place, Newcastle-on-Tyne, Alkali Works Inspector.
- O.M. Fletcher, F. W., c/o Fletcher, Fletcher & Co., Ltd., Holloway, N., Manufacturing Chemist.
1907. Fletcher, Henry T., c/o Aluminium Corporation, Ltd., Wallsend-on-Tyne, Works Manager.
1891. Fletcher, R. Jaques, North Geelong, Victoria, Manufacturing Chemist.
1904. Fletcher, Wm. E., Box 83, Tamaqua, Pa., U.S.A., Chemist.
1899. Focht, Louis, 105, E. Hanover Street, Trenton, N.J., U.S.A., Civil Engineer.
1890. Foden, Alfred, 19, Lancaster Avenue, Sefton Park, Liverpool, Metallurgical Chemist.
1900. Foersterling, Dr. H., c/o Roessler Hasslachier Chem. Co., Perth Amboy, N.J., U.S.A., Chemist.
1900. Fogetti, Lucien, 702, Wilson Avenue, Chicago, Ill., U.S.A., Chemist.
1895. Fogg, Chas. A., Graythorne, Albert Road, Bolton-le-Moors, Lecturer on Chemistry.
1901. Folsom, Herbert A., 112, Water Street, Boston, Mass., U.S.A., Textile Chemist.
1900. Forbes, Eli, Lancaster, Mass., U.S.A., Chemist.
1895. Forbes, Paul R., 15, William Street, New York City, U.S.A., Chemist and Assayer.
1893. Ford, J. B., jun., Michigan Alkali Co., Wyandotte, Mich., U.S.A., Secretary and Treasurer.
1889. Ford, Jno. S., Abbey Brewery, Edinburgh, Analyst.
1905. Foregger, Dr. R. von, c/o Roessler & Hasslachier Chemical Co., 100, William Street; and (Journals) P.O. Box 1999, New York City, U.S.A., Chemist.
1899. Forel, Geo., 212, Route de Vienne, Lyon (Rhône), France, Chemist.
1885. Formoy, J. Arthur, Oil Expert.
1904. Forrest, Chas. N., Maurer, N.J., U.S.A., Chemist.
1898. Forrest, J. Kerr, 271, Carlisle Street, St. Kilda, Victoria, Australia, Manufacturing Chemist.
1890. Forrester, A. M., c/o Richmond Guano Co., Richmond, Va., U.S.A., Analytical Chemist.
1905. Forrester, H. A., Usina de Gas, Retiro, Buenos Ayres, S. America, Chemical Works Manager.
1902. Forstall, Alf. E., 58, William Street, New York City, U.S.A., Consulting Gas Engineer.
1901. Forster, Miss E. L. B., King's College, Strand, London, W.C., Analyst.
1902. Forster, Ferdinand E. P., c/o Messrs. Bass and Co., 19, Guild Street, Burton-on-Trent, Chemist.
1907. Forster, Francis, Tyne Lead Works, Hebburn-on-Tyne, Lead Manufacturer.
1899. Forster, Dr. M. O., F.R.S., Royal College of Science, South Kensington, S.W., Demonstrator of Chemistry.
1884. Forster, Ralph C., c/o Messrs. Bessler, Waechter, and Co., Salisbury House, Finsbury Circus, London, E.C., Chemical Merchant.
1884. Forth, Henry, Meadowcroft, Marple, Cheshire, Drysalter.
1907. Forward, Charles C., Dept. of Inland Revenue Lab'y., 317, Queen Street, Ottawa, Canada, Chemist.
1908. Foster, Edward C., 273, Eddy Street, Providence, R.I., U.S.A., Chemical Manufacturer.
1906. Foster, Robt. K., 120, Victoria Parade, Collingwood, Melbourne, Victoria, Pharmaceutical Chemist.
- O.M. Foster, R. Le Neve, Bollindene, Wilmslow, Cheshire, Manufacturing Chemist.
1888. Foster, Wm., St. Martin's Terrace, Newton Park, Leeds, Manufacturing Chemist.
1903. Fotheringham, John, Lochaber, Lake Takapuna, Auckland, New Zealand, Chemist.
1906. Foulcar, J. Louis, 20, St. John's Park, Blackheath, S.E., Chemist.
1904. Foust, Thomas B., c/o Red River Furnace Co., Clarksville, Tenn., U.S.A., Chemist.
1907. Fowler, Chas., Liversedge Viarage, Yorks., Colour Makers' Representative.
1891. Fowler, Dr. Gilbert J., Broad Oak, Urnston, near Manchester, Consulting Chemist (Manchester Corporation Rivers Committee).
1898. Fowler, Theo. V., P.O. Box 168, Buffalo, N.Y., U.S.A., Chemical Works Manager.
1909. Fowler, Wm., 3, Cranbrook Road, Victoria Docks, London, E., Chemist.
1896. Fox, A. Stanley, Roselhurst, Athelstan Road, Faversham, Kent, Chemist (Cotton Powder Co., Ltd.).
1898. Fox, Jno., Varuna, Grappenhall, Cheshire, Analyst.
- O.M. Fox, T., jun., c/o Fox, Bros. and Co., Ltd., Wellington, Somerset, Wool Manufacturer.
1905. France, Edward W., Philadelphia Textile School, Broad and Pine Streets, Philadelphia, Pa., U.S.A., Director.
1885. Francis, Edwd., Park Ravine, Nottingham, Chemical Lecturer.
- O.M. Francis, E. G., 29, Matheson Road, West Kensington, W., Glucose Works Manager.
- O.M. Francis, G. B., 38, Southwark Street, London, S.E., Wholesale Druggist.
- O.M. Francis, W. H., 6F, Bickenhall Mansions, Gloucester Place, London, W., Wholesale Druggist.
1903. Francis, Dr. Aug., 4803, Garden Street, Bridesburg, Philadelphia, Pa., U.S.A., Chemist.
1906. Frank, Prof. Dr. A., Berlinerstrasse 26, Charlottenburg, Germany, Chemist.
1908. Frank, Dr. Fritz, Markgrafenstrasse 88, Berlin, S.W., 68, Germany, Public Analyst.
1891. Frank, Jerome W., 29, Broadway, New York City, U.S.A., Chemist.
1886. Frankenburg, Isidor, Greengate Rubber Works, Salford, Manchester, India-rubber Manufacturer.
1895. Frankforter, Dr. G. B., University of Minnesota, Minneapolis, Minn., U.S.A., Prof. of Chemistry.
1901. Frankl, A., Clothilde Chemical Works, Nagy Boeskö, Hungary, Chief Manager.
- O.M. Frankland, H., Streonshall, The Crescent, Linthorpe, Middlesbro', Analytical Chemist.
- O.M. Frankland, Prof. P. F., F.R.S., The University, Birmingham, Professor of Chemistry.
1906. Fraps, Geo. S., Texas A. & M. College, College Station, Texas, U.S.A., Professor of Chemistry.
1901. Fraseh, Hans A., 52, Broadway, New York City, U.S.A., Manager.

1900. Frasch, Herman, 82, Beaver Street, New York City, U.S.A., Oil Refiner.
1904. Fraser, Jas. D., 5, Millbrae Crescent, Langside, Glasgow, Chemist.
1891. Fraser, L. McG., 98, Commercial Road East, London, E., Chemical Engineer.
1907. Fraser, Wm. M., c/o The Texas Co., Port Arthur, Texas, U.S.A., Chemist.
1902. Frederiek, Geo. E., jun., P.O. Box 762, New York City, U.S.A., Chemical Merchant.
1885. Freear, H. M., Hardwick Road, Woburn Sands, Beds., Analytical Chemist.
1899. French, Alf., Dispenser.
1900. French, Thos., 1, Kelvin-side Terrace West, Glasgow, Chemist.
1903. Frerichs, Dr. F. W., Herf and Frerichs Chemical Co., and (Journals), 3828, Westminster Place, St. Louis, Mo., U.S.A., Manufacturing Chemist.
1907. Freytag, Henry, c/o Otto Isler and Co., Manchester, Chemical Merchant.
1886. Fries, Dr. Harold H., 92, Roade Street, New York City, U.S.A., Chemical Manufacturer.
1902. Fries, Jno. W., Winston Salem, N.C., U.S.A., Cotton Manufacturer.
1898. Frith, J. Mason, Linden Lodge, Runcorn, Cheshire, Lime Burner.
1899. Fritzsche, Karl, c/o Schimmel and Co., Miltitz, near Leipzig, Germany, Manufacturer of Essential Oils.
1890. Frost, Dr. Howard V., 3958, Drexel Boulevard, Chicago, Ill., U.S.A., Professor of Chemistry.
1884. Frost, Joe, Storth's Mill, Mold Green, Huddersfield, Manufacturing Chemist.
- O.M. Fryer, Dr. A. C., 13, Eaton Crescent, Clifton, Bristol, Alkali Works Inspector.
1904. Fryer, Percival J., 27, Munster Road, West Hampstead, N.W., Analyst.
1906. Fuchs, Herman C., 83, Marlborough Road, Brooklyn, N.Y., U.S.A., Dry Colour Chemist.
1903. Fudge, T., 604, Avenue E., Rayonne, N.J., U.S.A., Chemist.
1889. Fuerst, Jos. F., 17, Philpot Lane, London, E.C., Chemical and Oil Merchant.
1895. Fuerst, W. F., 2, Stone Street, New York City, U.S.A., Chemical Merchant.
1894. Fuller, Chas. J. P., 603, Chorley New Road, Horwich, near Bolton, Analytical Chemist.
1902. Fuller, Henry C., Bureau of Chemistry, Washington, D.C., U.S.A., Analytical Chemist.
1899. Fuller, Robt. F., Neston Park, Corsham, Wilts., Rubber Manufacturer.
1899. Fuller, W. M., c/o Morris and Griffin, Maindee, Newport, Mon., Chemical Manufacturer.
- O.M. Fuller, Wm., Vanbrugh Cottage, Maze Hill, S.E., Chemist.
1898. Fulmer, Elton, Pullman, Wash., U.S.A., Professor of Chemistry.
1896. Fulton-Smith, L., 20, Bold Street, Warrington, Brewer.
1885. Fyfe, Jno., 7, West George Street, Glasgow, Oil Works Director.
1897. Galletly, J. C., Technical College, Glasgow, Assistant to Professor of Chemistry.
1901. Gallivan, Dr. Frank B., 184, Summer Street, Boston, Mass., U.S.A., Chemist.
1903. Gallum, Albert F., Milwaukee, Wis., U.S.A., Tanner.
1901. Gallup, W. Arthur, Arnold Printworks, North Adams, Mass., U.S.A., Printer.
1901. Galpin, Harry T., 55, West 57th Street, New York City, U.S.A., Chemist.
1891. Galt, Hugh Allen, Columbia Chemical Co., Barberton, Ohio, U.S.A., Works Manager.
1887. Gamble, Jas. N., The Laboratory, Procter and Gamble Co., Ivorydale, Ohio, U.S.A., Soap Manufacturer and Oil Refiner.
1894. Gane, Eustace H., 95, Fulton Street, New York City, U.S.A., Pharmaceutical Chemist.
1888. Gans, Adolf, Farbenfabrik von L. Cassella & Co., Frankfurt a/Main, Germany, Dye Works Manager.
1901. Gansser, Dr. A., c/o Messrs. Lepetit, Dollfus & Gansser, Gressio-Ponte (Provincia di Cuneo), Italy, Chemical Engineer.
1896. Gardair, Aimé, 51, Rue St. Ferréol, Marseilles, France, Director of Chemical Co.
1907. Gardner, Edward, 70, Parliament Hill Mansions, Highgate Road, London, N.W., Metallurgical Chemist.
1905. Gardner, Franc E., 633, North Western Avenue, Chicago, Ill., U.S.A., President, Gardner-Barada Chemical Co.
1891. Gardner, Prof. Walter M., Technical College, Bradford, Director of Chemical and Dyeing Department.
1897. Garfield, Jos., Thackley, Bradford, Yorks., Civil Engineer.
1888. Garibabli, Joachim A., 21, Church Place, Gibraltar, Chemist.
1907. Garland, Herbert, Box 102, P.O., Khartoum, Sudan, Chemist (Government Laboratory).
1905. Garle, John L., 17, John Street, Bedford Row, London, W.C., Consulting Chemist.
1904. Garner, G. Lester, Monticello, Sullivan Co., N.Y., U.S.A., Superintendent of Leather Works.
1890. Garrett, Dr. F. C., Armstrong College, Newcastle-on-Tyne, Teacher of Science.
1900. Garrigues, W. E., Foot of Lieb Street, Detroit, Mich., U.S.A., Chemical Engineer.
1906. Garroway, Major John, 58, Buchanan Street, Glasgow, Chemist.
1898. Garry, H. Stanley, 2, Fletcher Gate, Nottingham, Manure Works Manager.
1908. Garson, Jas. W., 12, Avenue Road, Crouch End, N., Managing Director, Lewis Berger & Sons, Ltd.
1908. Garton, Joseph, 42, South John Street, St. Helens, Lancashire, Analytical Chemist.
- O.M. Garton, Sir Richard, Messrs. Hill, Garton, & Co., Southampton Wharf, Battersea, S.W., Glucose Manufacturer.
1886. Gascoyne, Dr. W. J., 27, South Gay Street, Baltimore, Md., U.S.A., Analytical Chemist.
- O.M. Gaskell, Holbrook, Erindale, Frodsham, Cheshire, Engineer.
1902. Gaskell, Holbrook, jun., Hillcroft, Church Road, Woolton, near Liverpool, Engineer.
1908. Gatchouse, Frank B., Analytical Laboratory, Broad Street, Bath, Chemist and Technical Journalist.
- O.M. Gatheral, Geo., 174, Solo Hill, Handsworth, Birmingham.
1906. Gauw, Percy, 78, Norman Road, Rusholme, Manchester, Chemist.
1903. Gaylord, Wallace K., Throop Polytechnic Institute, Pasadena, Cal., U.S.A., Professor of Chemistry.
1904. Gazdar, J. J., 5, Wroxham Mansions, 38, Canfield Gardens, South Hampstead, N.W., Barrister-at-Law.
1907. Geer, William C., 218, Park Street, Akron, Ohio, U.S.A., Chemist.

G

1891. Geisler, Dr. Jos. F., New York Mercantile Exchange Building, 6, Harrison St., New York City, U.S.A., Consulting Chemist.
1901. Gemmell, G. H., 4, Lindsay Place, George IV. Bridge, Edinburgh, Analytical Chemist.
1907. Gemmell, Wm., Walpole House, Church Street, Teddington, Middlesex, Analytical Chemist.
1901. Gent, Percy W., 697, Clifton Avenue, Forest Hill, Newark, N.J., U.S.A., Chemist.
1897. Gent, Wm. T., Springfield, Misterton, near Gainsboro', Metallurgical Chemist.
1896. Genth, Fred. A., jun., 222, Walnut Street, Philadelphia, Pa., U.S.A., Chemist.
1905. George, J. K., 345, Fifth Avenue, New York City, U.S.A., Manufacturer.
1908. Gerard, John B., The Soap Works, Nottingham, Soap Maker.
1906. Gerkenmeyer, Henry H., 109, South Eastern Avenue, Joliet, Ill., U.S.A., Chemist.
- O.M. Gerland, Dr. B. W., 105, Plantation Street, Acerington, Consulting Chemist.
1905. Geussler, Dr. Otto, Tuchmanufaktur Baron A.L. von Stieglitz, Narva, Russia, Chemist.
1903. Ghose, Anukul, 42, Shambazar Street, Calcutta, India, Analyst.
1908. Gianoli, Giuseppe, Piazza Cordusio 2, Milano, Italy, Chemical Engineer and Editor (L'Industria).
1908. Gibb, Wm. Doig, c/o Newcastle and Gateshead Gas Co., Tyneside Road, Newcastle-on-Tyne, Chief Engineer.
1903. Gibbings, Wm., Woodside, Halebank, Widnes, Works Manager.
1902. Gibbon, Edw., Belyedere, Park Road, Clydach, R.S.O., Glam., Works Chemist.
1904. Gibbs, A. E., Wyandotte, Mich., U.S.A., Manufacturing Chemist.
1883. Gibbs, D. Cecil, Soap Manufacturer.
- O.M. Gibbs, Wm. P., Cyanamidfabriken, Odda, Hardanger, Norway, Analytical Chemist.
1893. Gibbs, W. T., Buckingham, Prov. Quebec, Canada, Manufacturing Chemist.
- O.M. Gibson, Dr. J., 20, George Square, Edinburgh, Chemical Lecturer.
- O.M. Gibson, J. M., c/o Buckley Brick and Tile Co., Buckley, via Chester, Brick and Tile Manufacturer.
1905. Gibson, John, Victorian Portland Cement Works, Burnley Street North, Richmond, Vic., Australia, Manager.
1906. Gibson, Robt. R., Boise, Idaho, U.S.A., Chemist.
1905. Gibson, Wm. F., 18, Bushy Park, Totterdown, Bristol, Works Chemist.
1904. Giese, Otto E., 4, Cedar Street, Manhattan, New York City, U.S.A., Importer.
1899. Gifford, Wm. E., 408, New Jersey Railroad Avenue, Newark, N.J., U.S.A., Chemist.
1892. Gilbard, T. Francis H., 245, Dalston Lane, Hackney, N.E., Analytical Chemist.
1905. Gilbertson, Isaac H., 5, Broad Street, Rhodes, near Middleton, Lancs., Calico Printer.
1903. Gilby, Joseph W., c/o Brotherton and Co., Ltd., Haigh Park Chemical Works, Stourton, Leeds, Works Chemist.
- O.M. Gilchrist, Percy Carlyle, F.R.S., A.R.S.M., M.Inst.C.E. & M.E., Reform Club, Pall Mall, London, S.W.
1884. Gilchrist, Peter S., Charlotte, N.C., U.S.A., Chemical Engineer.
1900. Gildersleeve, W. H., Middleshoro', Ky., U.S.A., Chemist.
- O.M. Giles, W. B., The Grange, Leyton, Essex, Chemical Manufacturer.
1886. Gill, Dr. Aug. H., Massachusetts Institute of Technology, Boston, Mass., U.S.A., Assoc. Professor of Technical Analysis.
1901. Gill, Wm. S., c/o Farquhar and Gill, North of Scotland Colour Works, Aberdeen, Colour and Varnish Manufacturer.
1903. Gillean, R. Hampson, c/o General Chemical Co., Bayonne, N.J., U.S.A., Chemist.
1901. Gilles, Wm. S., The Cottage, Bocking, near Braintree, Essex, Technical Chemist.
1906. Gillies, Donald B., Apartado 125, Chihuahua, Mexico, Mining Engineer.
1888. Gillman, Gustave, Ferrocarril de Murcia á Granada, Aguilas, Prov. de Murcia, Spain, Civil Engineer.
1891. Ginningham, Edw. A., Croyland, Clapton Common, N., Electrician.
1886. Girdwood, Dr. G. P., 111, University Street, Montreal, Canada, Professor of Chemistry.
1906. Girtin, Thomas, H. L. Raphael's Refinery, Thomas Street, Burdett Road, London, E., Bullion Refiner.
1903. Gladding, Thos. S., 181, Front Street, New York City, U.S.A., Analytical Chemist.
1886. Glaeser, F. A., Carpenters' Road, Stratford, E., Varnish Manufacturer.
1906. Glasel, Dr. Chas. J., Nideggerstrasse 18, Düren, Rheinland, Germany, Tanner.
1889. Glaser, Chas., 22, South Gay Street, Baltimore, Md., U.S.A., Consulting Chemist.
1906. Glass, A. Melville, 37, Chancery Lane, London, W.C., Patent Agent.
1907. Gleason, Fred. J., Walpole, Mass., U.S.A., Superintendent (Mass. Chemical Co.).
1901. Glegg, Robt., Agricultural Laboratory, Marischal College, Aberdeen, Analytical Chemist.
1894. Glen, Chas., Glengowan Printworks, Caldercruix, N.B., Calico Printer.
1900. Glendenning, Arthur, 31, Bright Street, Middlesbrough, Analytical Chemist.
1884. Glendinning, H., Winnington Park, Northwich, Cheshire, Technical Chemist.
1888. Gloag, Robt. F., Grove Hill, Middlesbrough, Secretary.
- O.M. Glover, G. T., 24, Craven Hill Gardens, Lancaster Gate, W., Chemical Works Manager.
1896. Glover, H., East Falls, Schuylkill, Philadelphia, Pa., U.S.A., Chemical Works Superintendent.
1905. Glover, Nathan H., 355, River Street, Mattapan, Boston, Mass., U.S.A., Gum Manufacturer.
- O.M. Glover, William, Albareda 27, Seville, Spain, Technical Chemist.
1896. Goetz, Isidore, 5, Brondesbury Park, London, N.W., Mine Manager.
1907. Goldie, J. H. D., c/o Colonial Sugar Refining Co., Sydney, N.S.W., Australia, Chemist.
1898. Golding, Jno., Ashby Road, Kegworth, Derby, Agricultural Chemist.
1909. Goldman, M. Leon, The Crown Cock and Seal Co., 1511, Guilford Avenue, Baltimore, Md., U.S.A., Chemical Engineer.
1906. Goldschmidt, Dr. Karl, Chemical Works, Essen-Ruhr, Germany, Manufacturing Chemist.
- O.M. Goldschmidt, Dr. S. A., 43-51, Sedgwick Street, Brooklyn, N.Y., U.S.A., President (Columbia Chemical Works).
1897. Goldschmidt, Dr. Guido, Laboratory, II Salmgasse 1, Prag, Austria, Professor in Imperial German University.
1895. Goldsmith, Byron B., 19, East 74th Street, New York City, U.S.A., Vice-President (American Lead Pencil Co.).
1899. Goldsmith, Dr. Jno. N., 55, Chancery Lane, London, W.C., Chemist.
1906. Goodall, Wm. Leslie, Finboro' Road, Stowmarket, Suffolk, Works Chemist.
1909. Goodban, Leonard, 43, Addison Gardens, London, W., Works Chemist.
1900. Goodechild, Wm. H., 31, Etchingham Park Road, Finchley, N., Chemist.
1898. Goode, J. Archibald, 36, Trent Road, Brixton Hill, S.W., Analytical Chemist.
1906. Goodhue, Leonard H., c/o Boston Rubber Shoe Co., Malden, Mass., U.S.A., Chemist.
1904. Gooding, E. Claude, Willow House, Washford, Somerset, Chemical Student.
1898. Goodrich, Chas. C., 2, Rector Street, New York City, U.S.A., Rubber Manufacturer.
1884. Goodwin, C. C., Racefield, St. Margaret's Road, Altrincham, Cheshire, Soapmaker.
1894. Goodwin, Dr. W. L., The School of Mining, Kingston, Canada, Professor of Chemistry.

- O.M. Goppelsroeder, Dr. F., Leimenstrasse 51, Basel, Switzerland, Professor of Chemistry.
1898. Gordon, Colin, Storers' Wharf, Wharf Road, Poplar, E., Chemical Engineer.
1884. Gordon, J. G., Queen Anne's Mansions, Westminster, S.W., Steel Manufacturer.
1908. Gordon, Read, c/o Gordon and Dillworth, 563-5, Greenwich Street, New York City, U.S.A., Food Manufacturer.
1905. Gorsline, Wm. H., 242, Culver Road, Rochester, N.Y., U.S.A., Secretary and Manager.
1891. Gorvin, Jno. C., 29, Bryn Road, Swansea, Assayer.
1897. Gossage, W. Winwood, Widnes, Lancashire, Soap Manufacturer.
1904. Gotthelf, August H., Hastings-on-Hudson, N.Y., U.S.A., Chemist.
1890. Goulding, Sir Wm. J., Bart., North Wall, Dublin, Manure Manufacturer.
1903. Govers, F. X., 250, Main Street, Owego, Tioga Co., N.Y., U.S.A., Manager and Chemist.
- O.M. Gowland, Prof. W., 13, Russell Road, Kensington, W., Professor of Metallurgy (Royal School of Mines).
1886. Goyder, G. A., 12, Pirie Street, Adelaide, South Australia, Chemist and Assayer.
1890. Grabfield, Dr. J. P., c/o Morris and Co., 35th Street and 11th Avenue, New York City, U.S.A., Chemist.
1906. Graesser, Norman H., Argoed Hall, Llangollen, N. Wales, Manufacturing Chemist.
1883. Graesser, R., Cefn, near Ruabon, North Wales, Manufacturing Chemist.
- O.M. Graham, Prof. C., The Reculvers, Hastings, Consulting Chemist.
- O.M. Graham, C. C., Oriel House, Scarborough, Yorks., Technical Chemist.
1908. Graham, Chas. W., 142, Bloor Street West, Toronto, Canada, Chemist.
1883. Grandage, H., City Chambers, 2, Darley Street, Bradford, Dyer.
1897. Granger, Dr. J. Darnell, 25, All Saints Street, Nottingham, and (Journals) Thelottstrasse 4, Augsburg, Germany, Analytical Chemist.
1905. Grant, Alexander, 13, Kilgraston Road, Edinburgh, Baker.
1903. Grant, Henry C., c/o Grasselli Chemical Co., 60, Wall Street, New York City, U.S.A., Manager.
1896. Graves, Geo. H., c/o General Chemical Co., Bridgeport, Conn., U.S.A., Manufacturing Chemist.
1896. Graves, Walter G., 1950, East 90th Street, Cleveland, Ohio, U.S.A., Chemist.
1884. Gray, G. Watson, 8, Inner Temple, Dale Street, Liverpool, Consulting Chemist and Assayer.
1907. Gray, Henry M., Broompark, Duffield, Derby, Engineer.
1904. Grav, Jas., Heymann's Laboratory, P.O. Box 3427, Johannesburg, Transvaal, Chemist.
1901. Gray, J. Campbell, Glengoyt, Strines, near Stockport, Printworks Chemist.
1886. Gray, Jno., 3, Victoria Drive, Rock Ferry, near Birkenhead, Technical Chemist.
1903. Gray, Jno. Lathrop, c/o Tide Water Oil Co., East 22nd Street, Bayonne, N.J., U.S.A., Assistant Superintendent (Paraffin Works).
1896. Gray, Dr. Thos., The Technical College, Glasgow, Professor of Technical Chemistry.
1905. Gray, W. B., Messrs. Lever Bros., Balmain, Sydney, N.S.W., Australia, Analytical Chemist.
1903. Gray, Wm. S., 76, William Street, New York City, U.S.A., Chemical Merchant.
1908. Gray, Wm. T., Port Credit, Ontario, Canada, Starch Manufacturer.
1901. Greaves, Albert E., c/o P. Spence and Sons, Ltd., Goole Alum Works, Goole, Yorks., Works Chemist.
1891. Greaves, I. A. R., Morton, Gainsborough, Brewer.
1894. Greaves, Wm., Coppee Coke Ovens, Pinxton, Alfreton, Chemical Engineer and Chemist.
1894. Greeff, R. W., 20, Eastcheap, London, E.C., Chemical Agent.
- O.M. Green, Prof. Arthur G., 49, Cardigan Road, Headingley, and Clothworkers' Department, The University, Leeds, Professor of Dyeing.
1907. Green, Clarence, c/o Nicholson and Co., Beaumont Works, St. Albans, Herts., Chemist.
1906. Green, Ernest, 113, Hulton Street, Moss Side, Manchester, Science Teacher.
- O.M. Green, H., Hayle Mill, Maidstone, Paper Manufacturer.
1896. Green, Jno. Wilberforce, 22, Alwyne Mansions, Wimbledon, S.W., Technical Chemist.
- O.M. Green, L., Lower Tovil, Maidstone, Paper Manufacturer.
1908. Green, Dr. W. Heber, Chemical Laboratory, University, Melbourne, Australia, Lecturer in Chemistry.
- O.M. Greenaway, A. J., The Orchard, Chertsey, Surrey, Sub-Editor of Chemical Society's Journal.
1906. Greene, George M., c/o Colgate and Co., Jersey City, N.J., U.S.A., Chemist.
1884. Greenhalgh, Jas. Herbert, Whitebirk, Green Mount, Bury, Lancs., Assistant Manager of Printworks.
1909. Greenhough, George D., 21, Mining Lane, London, E.C., Chemical Broker.
- O.M. Greenway, T. J., 60, Brookman's Buildings, Grenfell Street, Adelaide, South Australia, Metallurgist.
1902. Greenwood, Conrad V., Noyna, Dowhills Road, Blundellsands, Liverpool, Cotton Mill Manager.
1907. Greenwood, Herbert W., 16, Longland Road, Liscard, Cheshire, Metallurgical Chemist.
- O.M. Greenwood, Holmes, Regent House, Hartmann Street, Accrington, Lancashire, Technical Chemist.
1897. Gref, Anthony, 117, Hudson Street, New York City, U.S.A., Patent Lawyer.
1909. Gregory, Cecil H., The Morgan Crucible Co., Ltd., Battersea Works, London, S.W., Crucible Manufacturer.
1907. Gregory, Joshua C., 128, Wellington Street, Glasgow, Analytical and Consulting Chemist.
- O.M. Greville, H. L., 39, Croft Road, Bromley, Kent, Consulting Chemist.
1890. Griffin, Jno. R., Kemble Street, Kingsway, W.C., Chemical Apparatus Maker.
1886. Griffin, Martin L., Emerson Laboratory, 177, State Street, Springfield, Mass., U.S.A., Consulting Chemist.
1902. Griffiths, Manfred E., 4, Temple Road, Stowmarket, Suffolk, Explosives Chemist.
1894. Griffiths, Thos., The Cedars, Clapham Common, S.W., Manufacturing Chemist.
1902. Grimwade, Wilfrid R., 335-343, Spencer Street, West Melbourne, Vic., Australia, Manufacturing Chemist.
1900. Grimwood, Robt. G., 43, Leaside Avenue, Muswell Hill, N., Analytical Chemist.
- O.M. Grindley, J., Upper North Street, Poplar, London, E., Tar Distiller.
1905. Grip, August E., 495, Columbia Street, Brooklyn, N.Y., U.S.A., Chemical Engineer.
1888. Gripper, Harold, Great Central Railway, Gorton, Manchester, Analytical Chemist.
1909. Grist, John M., 10, Cumberland Avenue, Gravesend, Kent, Explosive Works Chemist.
1906. Groenewoud, Sidney H., 36, Grosvenor Road, Highbury, N., Analytical Chemist.
- O.M. Grossmann, Dr. J., 145, Plymouth Grove, Manchester, Consulting Chemist and Chemical Engineer.
1896. Grosvenor, W. M., jun., 1123, Broadway, New York City, U.S.A., Consulting Chemical Engineer.
1908. Grottanelli, Dr. F. W., Dinamite Nobel, Avigliana, Torino, Italy, Industrial Chemist.
- O.M. Groves, C. E., F.R.S., 352, Kennington Road, London, S.E., Chemist (Thames Conservancy).
1907. Groves, J. Stuart, 908, Adams Street, Wilmington, Del., U.S.A., Chemist.
1903. Grundy, F. Barnes, Red Lodge, King's Road, Richmond, Surrey, Technical Chemist.
1906. Guess, Geo. A., c/o Tennessee Copper Co., Copperhill, Tenn., U.S.A., Chemist.

1898. Guess, Harry A., c/o Federal Lead Co., Flat River, Mo., U.S.A., Chemist and Manager.
1899. Guild, Frank N., University of Arizona, Tucson, Arizona, U.S.A., Professor of Chemistry.
1906. Gulline, Percy, Merrimack Manufacturing Co., Lowell, Mass., U.S.A., Printworks Superintendent.
1904. Gundlach, Walter, 370, St. Nicholas Avenue, New York City, U.S.A., Superintendent of Colour Works.
1905. Gundlach, Dr. Charles, c/o Thorium Chemical Co., Maywood, N.J., U.S.A., Technical Chemist.
1908. Gunn, Andrew, c/o Gunn's, Ltd., West Toronto, Canada, Pork Butcher.
1903. Gunn, Gilbert, 181, Bury New Road, Heywood, Lancs., Paper Mill Chemist.
1900. Günther, Chas. E., Liebig's Extract of Meat Co., Ltd., 4, Lloyd's Avenue, London, E.C., Merchant.
1902. Günther, Wm. J. W., c/o Colonial Sugar Refining Co., Ltd., 1, O'Connell Street, Sydney, N.S.W., Australia, Inspector.
1907. Gurgenzian, Dr. Gregor, Oilport, San Luis Obispo Co., Cal., U.S.A., Petroleum Refiner.
1894. Gurney, J. Clare, Fundición de Plomo de D. Miguel Zapata, Portman, Prov. de Murcia, Spain, Analytical Chemist.
1899. Gutcher, Wm., Singapore Oil Mills, Singapore, S.S., Superintendent Engineer.
1903. Guthrie, Alan, c/o Cooper, Allen, and Co., Cawnpore, India, Leather Chemist.
1901. Guthrie, John M., 199, Ferry Road, Leith, N.B., Analytical Chemist.
1903. Guttman, Dr. Leo F., College of the City of New York, New York City, U.S.A., Research Chemist.
1892. Guttman, Oscar, 60, Mark Lane, London, E.C., Consulting Chemical Engineer, M.Inst.C.E.
1904. Gyr, Dr. K. H., Zug, Switzerland, Analytical Chemist.
- H**
1902. Haas, Herbert, 61, Fremont Street, San Francisco, Cal., U.S.A., Metallurgical Engineer.
1904. Haeking, D. H., c/o East Lancashire Soap Co., Ltd., Clayton-le-Moors, near Acerrington, Lancs., Soap Manufacturer.
1900. Haddock, Arthur G., 60, Highbury, Newcastle-on-Tyne, Technical Chemist.
1898. Haddow, Geo., Parkview, Redding, Polmont Station, N.B., Chemist.
1887. Hadfield, Sir Robert A., Hecla Works, Sheffield; 28, Hertford Street, Mayfair, London, W., and (Journals) Parkhead House, Sheffield, Steel Founder.
1884. Hadkinson, F., Pamphila Oil and Soap Works, Mitylene, Mediterranean, Oil Refiner and Soap Manufacturer.
- O.M. Hadkinson, R., Smyrna, Asia Minor, Oil Refiner.
1904. Hadley, Geo., 58, Halesowen Street, Blackheath, Staffs., Spelter Works Manager.
1906. Haeefe, J. E., 44, Randolph Avenue, East Rutherford, N.J., U.S.A., Chemist.
1902. Hafl, Max M., Laboratory, 188, Metcalfe Street, Ottawa, Canada, Chemist.
1906. Hagen, Dr. Carl, 47, Victoria Street, London, S.W.
1887. Haig, Robert, Dollarfield, Dollar, N.B., Chemical Engineer.
1904. Haigh, B. Wilson, By-Product Coke Oven Dept., Barnsley Main Colliery, Barnsley, Yorks., Chemical Engineer.
1896. Haigh, De Lagnel, 39, Hill Crest, Summit, N.J., U.S.A., Chemist.
1888. Hailes, A. J. de, 15, Red Lion Square, London, W.C., Analytical Chemist.
1889. Haines, Reuben, Haines Street, near Chew Street, Germantown, Philadelphia, Pa., U.S.A., Analytical Chemist.
- O.M. Hake, C. N., 423, Flinders Lane, Melbourne, Victoria, Australia, Inspector of Explosives.
1908. Hakim Ali, Prof. M., Islamiah College, Lahore, Punjab, India, Professor of Physical Science.
1903. Halbert, Thos., c/o British South African Explosives Co., Modderfontein, Transvaal, Chemist.
1888. Hale, Edw. P., Endmoor, near Kendal, Analytical Chemist.
1908. Hales, Walter Wm., 7, Platt Street, New York City, U.S.A., Dyestuff Salesman.
1887. Hall, Allan T., c/o Sissons Bros. and Co., Ltd., Hull, Oil Refiner and Varnish Manufacturer.
1905. Hall, Archibald A., Armstrong College, Newcastle-on-Tyne, Demonstrator in Chemistry.
1898. Hall, Clarence A., 216, Penna. Arcade Building, Philadelphia, Pa., U.S.A., Chemist.
- O.M. Hall, Edgar, Silver Spur, Stanthorpe, Queensland, Australia, Technical Chemist.
1902. Hall, Henry, c/o Booth and Co., Irk Vale Works, Middleton, Lancashire, Dyer and Finisher.
1893. Hall, Jas. W., Bombay, Baroda, and Central India Railway, Sabarmata, near Ahmedabad, India, Linsed Oil Mills Manager.
1885. Hall, Jno. A., Victoria Chemical Works, Victoria, British Columbia, Analytical Chemist.
1908. Hall, John S., Manor House, Overseal, Ashby-de-la-Zouch, Chemical Student.
1900. Hall, Jos. J., 810, Sixth Avenue East, Cedar Rapids, Iowa, U.S.A., Chemist.
1896. Hall, S. Godfrey, East London Soap Works, Bow, E., Soap Maker.
1886. Haller, Geo., Sussex House, 52, Leadenhall Street, London, E.C., Chemical Merchant.
1893. Haller, H. Loft, 26, Seale Lane, Hull, Analytical Chemist.
1895. Halliwell, Edw., c/o Ribble Joint Committee, 2, Stanley Place, Preston, Chief Inspector.
1900. Hallock, Dr. Albert P., 440, First Avenue, New York City, U.S.A., Chemist.
1892. Hamaguchi, Gihei, Hiro Mura, Arida Gori, Wakayama Ken, Japan, Soy Manufacturer.
1897. Hambly, Fred. J., Buckingham, Quebec, Canada, Chemist.
1904. Hambuechen, Carl, 217, South Mills Street, Madison, Wis., U.S.A., Electro-Chemist.
1892. Hamilton, Robt., 40, Sefton Terrace, Beeston Hill, Leeds, Analytical Chemist.
1884. Hamilton, Robert, Glengarnock Chemical Co., Ltd., Glengarnock, N.B., Works Manager.
1898. Hammersley, W. Stanley, 5, Rue Seaffart, Soignies, Belgium, Tanner.
- O.M. Hammill, M. J., The Gables, St. Helens, Alkali Manufacturer.
- O.M. Hammond, J., Gas Works, Eastbourne, Sussex, Gas Manager.
1906. Hancock, H. Irving, Blue Point, N.Y., U.S.A., Chemist.
1905. Hancock, Thos. J., 29th Street and Bond Avenue, East St. Louis, Ill., U.S.A., Chemist.
1900. Hancock, Walter C., 10, Upper Chadwell Street, Myddelton Square, London, E.C., Chemist.
1896. Hand, Daniel, 50, Mount Pleasant Avenue, Newark, N.J., U.S.A., Chemist.
1889. Handy, Jas. O., 325, Water Street, Pittsburg, Pa., U.S.A., Chemist.
1888. Hanks, Abbot A., 425, Washington Street, San Francisco, Cal., U.S.A., Assayer.
1901. Hanna, Charles E., P.O. Box 2572, Montreal, Canada, Secretary.
1899. Hanna, Dillinger C., 4262, Parkside Avenue, Philadelphia, Pa., U.S.A., Chemist and Superintendent.
1905. Hanna, W. W., 109, North Water Street, Philadelphia, Pa., U.S.A., Aniline Colour Manufacturer.
1905. Hanson, H. Norman, Field Head, Brighouse, Yorks., Research Assistant.
1908. Hanson, W. G., c/o United States Glue Co., Milwaukee, Wis., U.S.A.
1905. Hareourt, Prof. R., Ontario Agricultural College, Guelph, Ont., Canada, Professor of Chemistry.
1904. Hard, Dr. James M. B., 2A, del Canadá, Colonia de Sta. Julia, Mexico, D.F., Chemist and Pathologist.

1901. Hardecastle, G. Fred., 29, Normanton Road, Leicester, Teacher of Science and Technology.
1894. Harden, Dr. Arthur, F.R.S., 2, Marlborough Road, Richmond, Surrey, Lecturer in Chemistry.
1908. Hardman, Benj., c/o British Leather Cloth Manufacturing Co., Newton, near Hyde, Lancashire, Analytical Chemist.
1900. Hardwick, W. Roscoe, 13, Batavia Buildings, Hackins Hey, Liverpool, Chemist.
1905. Hardy, Chas. H., c/o Reekitt & Sons, Ltd., Hull, Chemist.
1907. Harfeld, Louis E., 10, Elsworth Terrace, London, N.W., Merchant.
1906. Hargreaves, Frank, c/o The Electrolytic Alkali Co., Ltd., Middlewich, Cheshire, Chemist.
1896. Hargreaves, Jas., May Villa, Peel House Lane, Widnes, Lancashire, Chemical Engineer.
- O.M. Hargreaves, Jno., Widnes, Alkali Manufacturer.
1904. Harker, Dr. George, Chemist.
1893. Harlock, E. B., Newton House, Middlewich, Chemical Manufacturer.
1898. Harman, Edw. A., Gas Works, Huddersfield, Gas Engineer, M.Inst.C.E.
1905. Harper, Dr. Henry W., University of Texas, 2208, San Antonio Street, Austin, Texas, U.S.A., Professor of Chemistry.
1893. Harris, Arthur, 22, Marsh Gate Lane, Stratford, E., Soap Maker.
1885. Harris, Booth, jun., Beeleigh, Victoria Road, Buckhurst Hill, Essex, Soap Maker.
- O.M. Harris, David, F.R.S.E., Lyncombe Rise, Prior Park Road, Bath, Chemical Manufacturer.
1897. Harris, Fred. W., Corporation Chemical Department, 26, John Street, Glasgow, Public Analyst.
1907. Harris, John B., Danforth Avenue, Toronto, Canada, Manufacturer of Glues and Fertilisers.
1906. Harris, Jonathan W., c/o Western Electric Co., 463, West Street, New York City, U.S.A., Chemist.
1900. Harris, L. A., 18, North 18th Street, East Orange, N.J., U.S.A., Chemist.
1907. Harris, Thos. E., c/o The Union Acid Co., 17, Cooper Street, Manchester, Chemical Merchant.
1906. Harris, Wm. G., jun., 25, William Street, Toronto, Canada, Metallurgist.
- O.M. Harrison, A., Thames Sugar Refinery, Silvertown, London, E., Sugar Works Chemist.
1905. Harrison, E. P., Langholm, Edgar Road, South Croydon, Analytical Chemist.
1883. Harrison, G. Herbert, Hagley, Stourbridge, Chemist.
1904. Harrison, H. E., 1688, Buckingham Place, Chicago, Ill., U.S.A., Chemist.
1892. Harrison, Prof. John B., C.M.G., Government Laboratory, Georgetown, British Guiana, Government Analyst.
1907. Harrison, W., 14, Devonshire Place, Ardwick, Manchester, Chemist.
1898. Harrison, Wm. H., Coimbatore, India, Agricultural Chemist (Government of Madras).
1896. Hart, Bertram, c/o Tennants and Co., Clayton, Manchester, Analyst.
1886. Hart, Bertram H., Rosslyn, High Street, Sidemp, Kent, Analytical Chemist.
- O.M. Hart, Dr. E., Gayley Hall, Lafayette College, Easton, Pa., U.S.A., Professor of Chemistry.
1905. Hart, George Adam, Sewage Engineers' Office, Municipal Buildings, Leeds, Civil Engineer.
1890. Hart, H. W., 5, Cambridge Road, Ainsdell, Lytham, Lancashire, Analytical Chemist.
1897. Hart, Wm. Beaumont, Manchester Laboratory, 8, Exchange Street, Manchester, Consulting Chemist.
1908. Hartley, Bernard C., 3, Seafield Road, New Ferry, Cheshire, Analytical Chemist.
1883. Hartley, Joseph, Technical Chemist.
1889. Hartley, R. Kent, Springwood House, Middleton Junction, near Manchester, Chemical Works Manager.
- O.M. Hartley, Prof. W. N., D.Sc., F.R.S., Royal College of Science, Dublin, Professor of Chemistry.
1897. Hartmann, Ernest E., c/o United Club, No. 4, Yokohama, Japan, Chemist.
1905. Hartshorne, Wm. D., 40, Pleasant Street; and (Journals), Arlington Mills, Methuen, Mass., U.S.A. Agent.
1901. Hartwell, S. Warren, 119, West Walnut Lane, Germantown, Philadelphia, Pa., U.S.A., Chemist.
1901. Hartzell, Harry S., 126, North 4th Street, Allentown, Pa., U.S.A., Chemist.
1908. Harvey, Arthur J., 39, Burges Road, East Ham, E., Chemist.
1885. Harvey, Ernest W., Stoneleigh, Grove Road, Clapham Park, S.W., A.R.S.M., Engineer.
1908. Harvey, John G., 474, Gerard Street, East Toronto, Canada, Manufacturing Chemist.
1891. Harvey, Sidney, South-Eastern Laboratory, Canterbury, Analytical Chemist.
1899. Harvey, Thos. F., 84, Henry Road, West Bridgford, Nottingham, Analyst (Drug Co.).
1883. Harvey, T. H., Cattedown, Plymouth, Chemical Manufacturer.
1908. Harvey, Wm. Ross, c/o R. Lehmann and Co., Ltd., Peninsular House, Monument Street, London, E.C., Starch Manufacturer.
1903. Hasenclever, Max, Chemische Fabrik Rhenania, Aachen, Prussia, Chemical Manufacturer.
1906. Haskell, Walter E., 234, Bridge Street, Westbrook, Maine, U.S.A., Textile Chemist and Colourist.
1900. Haslwanter, Chas., 447, Spruce Street, Richmond Hill, Long Is., N.Y., U.S.A., Analytical Chemist.
1897. Hasslacher, Jacob, P.O. Box 1999, New York City, U.S.A., President, Boessler-Hasslacher Chemical Co.
1903. Hatschek, Emil, c/o S. Barnett and Co., Ltd., 19, St. Dunstan's Hill, London, E.C., Engineer.
1887. Hatton, Wm. P., c/o W. R. Hatton and Sons, Wormwood Scrubs, W., Starch Works Manager.
1906. Hattrick, J. M., 7, Bridge Street, Sydney, N.S.W., Australia, Local Manager (Potash Syndicate).
1900. Havens, Dr. F. S., 5822, Ashland Avenue, Philadelphia, Pa., U.S.A., Silk Conditioner.
1906. Havercroft, Arthur E., Glenholme, Burton Road, Horsea, Yorks., Chemist.
1899. Hawdon, H. S., Cleadon, near Sunderland, Manager.
1895. Hawker, E. W., Gladstone Chambers, Adelaide, South Australia, Metallurgist.
1902. Hawkins, Clement C., c/o The Texas Co., Port Neches, Texas, U.S.A., Chemist.
1897. Hawkins, Ernest M., Watling Chambers, Canterbury, Chemist.
1905. Hawkins, Henry, Moyola Villa, Lansdown, Limerick, Ireland, Gas Engineer.
1893. Hawkins, J. Dawson, c/o U. S. Reduction and Refining Co., Colorado Springs, Colo., U.S.A., President and General Manager.
1887. Hawliczek, Josef, c/o United Alkali Co., Sullivan Works, Widnes, Consulting Chemical Expert.
1899. Haworth, Dr. Edw., Sunnyside, Norman Road, Runcorn, Cheshire, Chemist.
1903. Haworth, Herbert, Crown Works, Appley Bridge, near Wigan, Director (Grove Chemical Co.).
1904. Hawthorn, J. H., Municipal Technical School, Leicester, Head Master.
1895. Hay, Alex. B., Kelyindock Chemical Works, Maryhill, Glasgow, Manufacturing Chemist.
1904. Hayman, Jack V. J., c/o Société Anon. des Ciments, Massarah, Lignede Belouan, Cairo, Egypt, Chemist.
1894. Haynes, David O., 90, William Street, New York City, U.S.A., Proprietor, "Pharmaceutical Era."
1902. Hays, E. F., c/o E. R. Squibb and Sons, 80, Beekman Street, New York City, U.S.A., Chemist.
1906. Hayworth, W. P., 47, Highfield Road, Dartford, Kent, Chemist.
1905. Hazard, Fred. R., P.O. Box 2, Syracuse, N.Y., U.S.A., President (Solvay Process Co.).
1903. Hazen, Chas. R., 258, Prince Albert Avenue, Westmount, Quebec, Canada, Chemist.
1894. Heul, Carlton, Dalston House, Dumfries, N.B., Tamer.

1903. Heald, Henry I., Hove House, Adwick Road, Mexborough, near Rotherham, Yorks., Manager of Earthenware Factory.
- O.M. Heath, R. C., Myton Grange, near Warwick, Chemical Manufacturer.
1905. Heathcote, Henry L., Warwick Avenue, Earlsdon, Coventry, Research Chemist.
1904. Heaton, Noel, 20, Baker Road, Harlesden, N.W., Colour Manufacturer.
1895. Hebdon, Jno. C., P.O. Box 465, Providence, R.I., U.S.A., Works Manager and Chemist.
1905. Heberlein, Dr. Edw., c/o H. T. Enthoven & Sons, Ltd., 247, Rotherhithe Street, London, S.E., Works Manager.
1889. Hecht, Jos. L., Bettendorf Metal Wheel Co., Davenport, Iowa, U.S.A., Analytical Chemist.
1900. Heckman, J. Conrad, Larkin Soap Manufacturing Co., Seneca Street, Buffalo, N.Y., U.S.A., Chemist.
1885. Hedley, Armorer, Durrant House, Bournemouth, Hants.
1902. Heebner, Prof. Chas. F., Ontario College of Pharmacy, Toronto, Canada, Professor of Pharmaceutical Chemistry.
1903. Hegeman, John W., 102, Barbey Street, Brooklyn, N.Y., U.S.A., Chemist.
1906. Hehner, Charles, 155, Dunn Avenue, Parkdale, Toronto, Canada, Assistant Manager.
- O.M. Hehner, Otto, 11, Billiter Square, London, E.C., Analytical and Consulting Chemist.
1908. Heilmann, Dr. Ernst, Güstrow, Mecklenburg, Germany, Chemical Manufacturer.
1887. Hellier, E. A., Avonside Varnish Works, St. Philip's Marsh, Bristol, Varnish Manufacturer.
1885. Hellon, Dr. R., 40, New Lowther Street, Whitehaven, Analytical and Consulting Chemist.
1903. Helps, D. H., c/o Reading Gas Co., King's Road Works, Reading, Engineer and Manager.
1908. Helps, James W., Gas Works, Waddon, Croydon, General Manager, Gas Co.
1898. Hemingway, Frank C. R., 133, Front Street, New York City, U.S.A.
1883. Hemingway, H., 9, Albemarle Mansions, Hampstead, N.W., Chemical Manufacturer.
1884. Hempleman, F. S., 39, Brunswick Terrace, Hove, Sussex, Manure Manufacturer.
1903. Hemstreet, George P., Hastings-on-Hudson, N.Y., U.S.A., Mechanical Engineer.
1883. Henderson, Prof. G. G., The Technical College, George Street, Glasgow, Professor of Chemistry.
1902. Henderson, Prof. Jas. A. Russell, Chihli Provincial College, Paotingfu, North China, Professor of Chemistry and Physics.
1900. Henderson, J. Brownlie, Government Analyst's Office, Brisbane, Queensland, Government Analyst.
1902. Henderson, J. C. A., 120, Bishopsgate Street Within, London, E.C.
1894. Henderson, Jos., Eskbank Ironworks, Lithgow, N.S.W., Australia, Blast Furnace Manager.
1894. Henderson, Norman M., Broxburn Lodge, Broxburn, N.B., Oil Works Manager.
- O.M. Henderson, W. F., Moorfield, Claremont Gardens, Newcastle-on-Tyne.
1893. Hendrick, Jas., Marischal College, Aberdeen, Lecturer on Agricultural Chemistry.
1906. Henius, Dr. Max, 327, Fullerton Avenue, Chicago, Ill., U.S.A., Secretary, Brewers' School.
1904. Henley, Hon. F. R., 9, Beaufort Gardens, London, S.W., Brewers' Chemist.
1889. Hennin, Alphonse, Portoferraio, Isola d'Elba, Italy, Metallurgical Chemist.
1905. Henning, Albert, 92, Harrow Road, Leytonstone, N.E., Chemical Manufacturer.
1906. Henning, C. I. B., c/o E. I. du Pont de Nemours Powder Co., Haskell, N.J., U.S.A., Chemist.
1894. Henshaw, Sam., Glenlithorne, Wolstanton, Stoke-on-Trent, Chemical Works Manager.
1908. Henzell, Chas. G., 19, Cardigan Road, Leeds, Waterworks Engineer.
1906. Herig, Harry W., 35, Rose Avenue, Jersey City, N.J., U.S.A., Chemist.
1891. Heriot, T. H. P., 37, Church Crescent, Muswell Hill, N., Analytical Chemist.
1908. Herlin, Chas., Nitroglycerin Aktiebolaget, Stockholm 2, Sweden, Chemical Engineer.
- O.M. Herman, W. D., Holm Lea, Rainhill, Lancashire, Glass Works Chemist.
- O.M. Heron, John, 110, Finchurch Street, London, E.C., Brewing Chemist.
1903. Herreshoff, J. B. F., 40, West 69th Street, New York City, U.S.A., Chemical Engineer.
1887. Herriot, Wm. Scott, Ravenswood, Partickhill, Glasgow, Mechanical Engineer.
- O.M. Herrmann, R. W., 59, Mark Lane, London, E.C., Chemical Merchant.
1891. Hersam, Ernest A., University of California, Berkeley, Cal., U.S.A., Assistant Professor of Metallurgy.
1898. Hersey, Dr. Milton L., P.O. Box 554, Montreal, Canada, Consulting Chemist.
1901. Hershey, Aldus N., c/o Sharpe and Dohme, Baltimore, Md., U.S.A., Chemist.
1903. Herstein, Dr. Bernard, Dept. of Agriculture, Bureau of Chemistry, Washington, D.C., U.S.A., Technical Chemist.
1906. Herty, Prof. Chas. H., University of N. Carolina, Chapel Hill, N.C., U.S.A., Professor of Chemistry.
1906. Herz, Dr. Albert, Rosemount, Hipperholme, Halifax, Yorks., Chemist.
1885. Hess, Dr. Adolph, Kirkstall Road, Leeds, Chemical Manufacturer.
1907. Hess, Arthur F., c/o A. Hess & Bro., Ltd., Kirkstall Road, Leeds, Oil Distiller.
1904. Hess, H. W., c/o Libbey Glass Co., Toledo, Ohio, U.S.A., Chemist.
1905. Hesse, Dr. Bernhard C., 90, William Street, New York City, U.S.A., Chemist.
1891. Hetherington, Dr. Albert E., Ammonia Soda Works, Fleetwood, Lancashire, Analytical Chemist.
1904. Heinrich, Christian, 1307, New Hampshire Avenue N.W., Washington, D.C., U.S.A., Brewer.
1894. Hewitt, A. H., The Green Island Cement Co., Ltd., Hong Kong, China, Engineer.
- O.M. Hewitt, Dr. D. B., Grove Mount, Davenham, Cheshire, Alkali Manufacturer.
1903. Hewitt, H. R., 18, Meade Street, Longsight, Manchester, Chemical Works Manager.
1896. Hewitt, Dr. J. Theo., 14, The Avenue, Surbiton, Lecturer.
1890. Hewlett, John C., 40-42, Charlotte Street, Great Eastern Street, London, E.C., Manufacturing Chemist.
1907. Hewson, Geo. W., 22, Palmer Street, Jarrow-on-Tyne, Analytical Chemist.
1893. Hey, Harry, 2, Ash Terrace, Savile Town, Dewsbury, Dyer.
1906. Heyes, Charles H., 124, Yonge Street, Toronto, Canada, Consulting Chemist.
1881. Heyes, W. E., Llanberis, Bushey Hall Road, Watford, Consulting Engineer.
1906. Hibbert, John C., 6, Victoria Road, West Bridgford, Nottingham, Chemist.
1901. Hiby, Dr. Walter, 4, Southampton Row, London, W.C., Chemical Engineer.
1906. Hicking, W. Norton, Queen's Road Works, Nottingham, Lace Dresser.
1906. Hickman, T. Moore, Holmdale, Penn Road, Wolverhampton, Analyst.
1897. Hicks, Edwin F., 4837, Fairmount Avenue, Philadelphia, Pa., U.S.A., Analytical Chemist.
1893. Hicks, Jas. A., c/o Sir Boyerton Redwood, 4, Bishopsgate Street Within, London, E.C., Analytical Chemist.
- O.M. Higgin, W. H., Hollywood, Lostock, near Bolton-le-Moors, Chemical Manufacturer.
1886. Higgins, C. L., 79, Bedford Street South, Liverpool, Manufacturing Chemist.
1905. Higgins, Dr. Eric, 5, Rolleston Drive, Wallasey, Cheshire, Chemist.
1905. Higgins, John M., 39, Queen Street, Melbourne, Vic., Australia, Consulting Metallurgist.

1908. Higgins, S. H., Luncarty Bleachfield, Perth, N.B., Chemist and Asst. Manager.
1907. Hikida, Keitaro, Tokyo Higher Technological School, Asakusa, Tokyo, Japan.
1908. Hill, A. Bostock, 14, Temple Street, Birmingham, Public Analyst.
1908. Hill, A. Clarence, c/o Pinchin, Johnson, & Co., Ltd., Minerva House, Bevis Marks, London, E.C., Managing Director.
1903. Hill, Chas. Alex., 64, Park Street, Southwark, S.E., Chemist.
1897. Hill, George, Barton-on-Humber, Chemical Works Manager.
1897. Hill, Dr. Herbert M., University of Buffalo, N.Y., U.S.A., Professor of Chemistry and Toxicology.
1907. Hill, James A., 70, York Street, Runcorn, Cheshire, Technical Chemist.
1908. Hill, J. H. F., c/o Broken Hill Proprietary Co., Broken Hill, N.S.W., Australia, Mining Engineer.
- O.M. Hill, J. K., 13, Osborne Place, Copland Road, Govan, near Glasgow, Manufacturing Chemist.
1892. Hill, Sydney, Eastholme, Prince's Avenue, and (Journals) c/o Blundell, Spence & Co., Ltd., Hull, Analytical Chemist.
1903. Hill, W. Basil, Foss Islands Tannery, York, Tanner.
1902. Hill, Wm. G. H., jun., American Rubber Co., East Cambridge, Mass., U.S.A., Chemist.
1898. Hill-Jones, Thos., Invicta Mills, Bow Common Lane, London, E., Manufacturing Chemist.
- O.M. Hills, C. H., Anglesea Copper Works, Low Walker, Newcastle-on-Tyne, Copper Smelter.
1894. Hills, Harold F., Commercial Gas Works, Stepney, London, E., Analytical Chemist.
- O.M. Hills, W., 225, Oxford Street, London, W., Pharmaceutical Chemist.
1899. Hinchley, J. W., 85, Gracechurch Street, London, E.C., Chemical Engineer.
1904. Hinekey, J. F., c/o Jones Bros., Pearl and Water Streets, Brooklyn, N.Y., U.S.A., Chemical Engineer.
- O.M. Hindle, J. H., 8, Cobham Street, Accrington, Dye-works Manager.
1899. Hinks, Percy J., Danger Building Dept., Royal Laboratory, Woolwich Arsenal, S.E., Chemist.
1891. Hinman, Bertrand C., 48, Sydenham Hill, Sydenham, S.E., Metallurgical Chemist.
1892. Hinshelwood, Thos., Glasgow Oil and Paint Works, Glenpark Street, Glasgow, Oil Refiner.
1905. Hiorns, A. H., Riga, Gravely Hill, near Birmingham, Science Teacher.
1903. Hirshfield, E., c/o United Chemical Co., 52, Broadway, New York City, U.S.A., Chemist.
1895. Hirst, H. Reginald, Bank House, Staincliffe, Batley, Yorks, Works Chemist.
1907. Hirt, Wilhelm B., c/o Cuming, Smith & Co., Ltd., Yarra Junction, Vic., Australia, Analytical Chemist.
1907. Hirtz, Dr. Heinrich, c/o Dr. L. Mond, F.R.S., 18, Avenue Road, London, N.W., Chemist.
1896. Hislop, Geo. R., (Journals) Gas Works, (communications) Greenhill House, Underwood Road, Paisley, N.B., Gas Engineer and Manager.
1900. Hobbs, Alex. F., c/o The United States Finishing Co., Box A, North Station, Providence, R.I., U.S.A., Printworks Superintendent.
1900. Hobbs, Dr. Perry L., Western Reserve Medical College, and (Journals) 2047, East 9th Street, Cleveland, Ohio, U.S.A., Professor of Chemistry.
1906. Hobsbaum, Isaac B., c/o Lockett Bros. and Co., Iquique, Chile, Analytical Chemist.
1905. Hobson, Alfred, Dantzic Brewery, Imperial Street, Regent Street, Leeds, Brewer and Wine Manufacturer.
1907. Hochstetter, Robt. W., Oak and Bellevue Avenues, Mount Auburn, Cincinnati, Ohio, U.S.A., Superintendent.
1894. Hodge, Andrew, Brookfield House, Whaley Bridge, near Stockport, Printworks Chemist.
1890. Hodges, Harry B., Long Island Railroad Co., Long Island City, N.Y., U.S.A., Chemical Engineer.
- O.M. Hodgkinson, Dr. W. R., 89, Shooters Hill Road, Blackheath, S.E., Professor of Chemistry.
- O.M. Hodgson, Chris., 33, Oakdale Road, Nether Edge, Sheffield, Metallurgical Chemist.
1897. Hodgson, Matthew, Ardmore, Church Hill, Wicklow, Ireland, Technical Chemist.
1890. Hodgson, Wm., 66, Deansgate, Manchester, Oil and Colour Broker.
1906. Hogarth, Julius W., The University, Sydney, N.S.W., Australia, Demonstrator of Chemistry.
1886. Hogben, W., Post Office, Port Talbot, South Wales, Chemical Expert (Celluloid, Ltd., etc.).
- O.M. Hogg, T. W., c/o John Spencer and Sons, Newburn Steelworks, Newcastle-on-Tyne, Metallurgical Chemist.
1905. Holcroft, Harold, Parkdale, Wolverhampton, Iron-founder.
1899. Holden, Archie Neill, c/o Hardman and Holden, Ltd., Miles Platting, Manchester, Chemist.
1887. Holden, G. H., Manchester Oxide Co., Ltd., Canal Street, Miles Platting, Manchester, Chemist.
1904. Holden, Norman N., c/o Hardman and Holden, Ltd., Colliery Lane, Clayton, Manchester, Manufacturing Chemist.
1902. Holdsworth, Ernest T., 10, Merton Road, Bradford, Dyer.
1904. Holgate, Arthur, c/o Wm. Holgate and Sons, Ltd., 15, Earle Street, Liverpool, Corn Miller.
1885. Holgate, T. E., 173, Hollins Grove, Darwen, Lancashire, Metallurgist.
1884. Holgate, Thos., 5, Victoria Street, Westminster, S.W., Gas Engineer.
- O.M. Holland, Philip, 22, Taviton Street, Gordon Square, London, W.C., Analytical Chemist.
1892. Holland, Philip H., 546, Sherbrooke Street West, Montreal, Canada, Merchant.
1901. Hollick, Herbert, 304, The Robeson, Camden, N.J., U.S.A., Chemical Engineer.
1902. Holliday, Lionel B., Lunelough Hall, Huddersfield, Chemical Manufacturer.
1896. Hollings, J. Spencer, Vrondeg, near Wrexham, North Wales, Works Manager.
1903. Hollinshead, Peter, 19, The Hollow Way, Runcorn, Cheshire, Chemist.
1900. Hollinshead, Dr. W. H., Wingrove Avenue, Nashville, Tenn., U.S.A., Teacher of Chemistry.
1904. Holloway, E. G., c/o Jas. S. Kirk and Co., 360, North Water Street, Chicago, Ill., U.S.A., Chemist.
1890. Holloway, G. T., 57-58, Chancery Lane, London, W.C., Analytical and Consulting Chemist.
1883. Holmes, Ellwood, Wyncote, Jesmond Park East, Newcastle-on-Tyne, Colour Manufacturer.
- O.M. Holmes, F. G., Northcroft, Tewitwell Road, Harrogate, Yorks., Technical Chemist.
1907. Holmes, Wm. E., Glenholme, Sandal, Wakefield, Yorks., Chemist.
1900. Holthouse, Harold B., 12, Melton Grove, West Bridgford, Notts., Chemist.
1902. Holton, Alf. L., Chemical Dept., Gas Works, Bradford Road, Manchester, Chemist.
1892. Holton, E. C., 601, Canal Road N.W., Cleveland, Ohio, U.S.A., Chemist.
1893. Holzapfel, Max, Milburn House, Newcastle-on-Tyne, Manufacturer.
1893. Homfray, D., The Hugs, Misterton, near Gainsborough, Analytical Chemist.
1905. Hook, Arthur Harry, c/o Tintie Smelting Co., Silver City, Utah, U.S.A., Chemist.
1904. Hooker, A. H., c/o The Development and Funding Co., Niagara Falls, N.Y., U.S.A., Manufacturing Chemist.
- O.M. Hooper, E. Grant, 16, Royal Avenue, Sloane Square, S.W., Chemist.
1889. Hooper, Ernest F., c/o Brotherton and Co., Ltd., Wear Tar Works, South Dock, Sunderland, Technical Chemist.
1888. Hope, Jas., The Nickel Co., Kirkintilloch, N.B., Nickel Works Manager.
1901. Hopewell, Fredk., 86, Yonville Square, Montreal, Canada, Manager.

1892. Hopkins, Erastus, Ocala, Fla., U.S.A., Consulting Chemist.
1905. Hoppenstedt, A. W., c/o Elk Tanning Co., Ridgway, Pa., U.S.A., Chemist.
1895. Horne, Dr. W. D., 175, Park Avenue, Yonkers, N.Y., U.S.A., Consulting Chemist.
1904. Hoinsey, J. W., Room 1026, 25, Broad Street, New York City, U.S.A., Chemical Engineer.
1900. Horsfall, Jno., 1 Grange Avenue, Rawtenstall, Manchester, Analytical and Consulting Chemist.
1902. Horsfall, L. H., c/o Bunny and Co., Madras, India, Chemist.
1901. Horton, Edw., jun., 10, Smith Street, Chelsea, S.W., Student.
1906. Hosenon, Jas. H., Sun Buildings, Bridge Street, Manchester, Chemical Manufacturer.
1902. Hosford, Roger F., 15, Dey Street, New York City, U.S.A., Chemical Engineer.
1890. Hoskins, A. Percy, Clonke, Rosetta Park, Belfast, Ireland, Analytical Chemist.
1899. Hoskins, Wm., Room 54, 81, South Clark Street, Chicago, Ill., U.S.A., Chemist.
1905. Hough, Warwick M., 902, Rialto Building, St. Louis, Mo., U.S.A., Attorney-at-Law.
1899. Houlder, Bertram E., 50, Lady Margaret Road, Southall, Middlesex, Chemist.
1892. Houston, John, 26, Princess Street, Manchester, Drysalter.
- O.M. Howard, A. G., Burnt House, Chigwell, Essex, Chemical Manufacturer.
1901. Howard, Bernard P., Quantocks, Montalt Road, Woodford Green, Essex, Chemist.
- O.M. Howard, D., Devon House, Buckhurst Hill, Essex, Chemical Manufacturer.
1887. Howard, D. Lloyd, City Mills, Stratford, E., Chemical Manufacturer.
1907. Howard, G. C., University Club, Salt Lake City, Utah, U.S.A., Chemist.
1898. Howard, Henry, 36, Amory Street, Brookline, Mass., U.S.A., Chemical Engineer.
1902. Howard, Nelson A., c/o General Chemical Co., Hegewisch, Ill., U.S.A., Chemist.
1904. Howard, T., 38, Bulstrode Road, Hounslow, W., Chemist.
- O.M. Howard, W. D., H. Cornwall Terrace, Regent's Park, London, N.W., Chemical Manufacturer.
1906. Howe, Chester A., 124, Purchase Street, Boston, Mass., U.S.A., Dyestuff Merchant.
1903. Howe, Jas. Lewis, Washington and Lee University, Lexington, Va., U.S.A., Professor of Chemistry.
1905. Howe, Roland E., 15, Highland Street, Concord Junction, Mass., U.S.A., Explosives Chemist.
1904. Howell, Walter L., Room U, Custom House, New Orleans, La., U.S.A., Chemist.
1899. Howles, Fred., c/o McDougall Bros., 66-68, Port Street, Manchester, Chemist.
1889. Howorth, F. Wise, 46, Lincoln's Inn Fields, W.C., Technical Chemist and Chartered Patent Agent.
1907. Howroyd, Richard R., c/o Calder Mersey Extract Co., Ltd., Ditton, near Widnes, Chemist.
1906. Hoyler, Fritz, 49, Market Street, Perth Amboy, N.J., U.S.A., Chemist.
1896. Hoyte, Percy S., Gas Works, Coxside, Plymouth, Gas Engineer.
1900. Hübner, Julius, Ash Villa, Cleidle Hulme, Cheshire, Director of Dyeing and Papermaking Departments (Municipal School of Technology).
1902. Hudson, C. Edward, c/o E. G. Jepson and Co., Albion Walk Chambers, Leeds, Drysalter.
1899. Hudson, Dr. Edw. J., c/o Pioneer Iron Co., Marquette, Mich., U.S.A., Chemist.
1905. Hudson, O. F., The University, Edgbaston, Birmingham, Lecturer on Metallurgy.
- O.M. Hughes, J., 79, Mark Lane, London, E.C., Agricultural Chemist.
1898. Hughes, Raymond M., Miami University, Oxford, Butler Co., Ohio, U.S.A., Professor of Chemistry and Physics.
1908. Hughes, Wm. E., Chemical Laboratory, Messrs. W. Canning and Co., Great Hampton Street, Birmingham, Electro Chemist.
1906. Hulme, Robert B., Bureau of Chemistry, Room D. 15, Produce Exchange, New York City, U.S.A., Chemist.
1905. Hulton, H. F. E., 11, Colinet Road, Putney, S.W., Chemist.
1905. Humel, Edward J., Lake Avenue, cor. Edward Street, Lakewood, Cleveland, Ohio, U.S.A., Chemist.
1893. Humphrey, Chas., Hilderstone, Hartford, Cheshire, Alkali Works Manager.
1902. Humphrey, Rich. L., 1001, Harrison Building, Philadelphia, Pa., U.S.A., Civil Engineer.
1903. Humphreys, A. C., 165, Broadway, New York City, U.S.A., Engineer.
1908. Humphries, Albert E., Coxes Lock Mill, Weybridge, Surrey, Flour Miller.
- O.M. Humphrys, N. H., Gasworks, Salisbury, Wilts, Gas Engineer.
1895. Hunicker, Dr. H. Aug., 3532, Victor Street, St. Louis, Mo., U.S.A., Prof. of Applied Chemistry.
1900. Hunt, Arthur V., 284, New Chester Road, Port Sunlight, Cheshire, Analytical Chemist.
- O.M. Hunt, Bertram, 709, Mills Building, San Francisco, Cal., U.S.A., Technical Chemist.
- O.M. Hunt, Chas., 17, Victoria Street, Westminster, London, S.W., Gas Engineer.
1883. Hunt, J. S., Appleton, Widnes.
1903. Hunt, P. C., Holmes, Metropolitan Gas Co., Flinders Street, Melbourne, Vic., Australia, Gas Engineer.
- O.M. Hunt, W., Hampton House, Wood Green, Weynesbury, Staffordshire, Chemical Manufacturer.
1903. Hunter, H. B., Denney Factory, St. Lucia, West Indies, Sugar Works Manager.
1902. Hunter, Hy. Blount, Hunter Chemical Co., Norfolk, Va., U.S.A., Industrial Chemist.
1893. Hunter, Prof. Matthew, Rangoon College, Rangoon, Burmah, Professor of Chemistry.
- O.M. Huntington, Prof. A. K., King's College, Strand, London, W.C., Professor of Metallurgy.
1902. Huntly, Geo. X., 96, Gower Street, London, W.C., Analytical and Consulting Chemist.
1904. Huntzinger, Alfred, Route de Condette, Pont de Briques, Pas de Calais, France, Chemist and Colourist.
1903. Hurlburt, Allen S., c/o General Chemical Co., Camden, N.J., U.S.A., Chemist.
1904. Hurren, F. H., c/o The Rover Co., Ltd., Coventry, Analytical Chemist.
1894. Hurry, E. H., Goodwyns, Haslemere, Surrey, Mechanical Engineer.
- O.M. Huson, C. W., 18, Batavia Buildings, Hackins Hey, Liverpool, Analytical Chemist.
1908. Hutcheson, John, c/o Farbenfabriken of Elberfeld Co., 14, Front Street East, Toronto, Canada, Local Manager.
1894. Hutcheson, Jno. F., 22, St. Enoch Square, Glasgow, Chemical Manufacturer.
1906. Hutchings, W. Maynard, Easedale, Elmfield Road, Gosforth, Newcastle-on-Tyne, Metallurgist.
- O.M. Hutchinson, C. C., 3, Harcourt Buildings, Temple, E.C., Barrister-at-Law and Chemical Engineer.
1900. Hutchinson, E. George, Gas Works, Stockport, Gas Engineer.
- O.M. Hutchinson, T. J., Aden House, Manchester Road, Bury, Analytical and Consulting Chemist.
1901. Hutton, Dr. Robt. S., West Street, Sheffield, Lecturer on Electro-Chemistry.
- O.M. Huxley, Jas. H., c/o Vickers, Son and Maxim, Ltd., River Don Works, Sheffield, Metallurgical Chemist.
1906. Huyett, Miles C., 608, Morgan Building, Buffalo, N.Y., U.S.A., Mechanical Engineer.
1897. Hyams, Godfrey M., 312, Sears Building, Boston, Mass., U.S.A., Mines Manager.
1902. Hyde, Austin T., Box 98, Rumford Falls, Maine, U.S.A., Chemical Engineer.
1897. Hyde, B. T. Babbitt, 82, Washington Street, New York City, U.S.A., Soap Manufacturer.
1899. Hyde, Fred. S., 215, Schermerhorn Street, Brooklyn, N.Y., U.S.A., Research Chemist.

1899. Hyde, Wm. Grantley, Garden Wharf, Church Road, Battersea, S.W., Assayer.
 1901. Hyman, Leonard W., 342, South Pearl Street, Albany, N.Y., U.S.A., Analytical Chemist.

I

1898. Ibbotson, E. C., jun., A. B. Electrostat, Trollhattan, Sweden, Metallurgist.
 1900. Ichioka, Tajiro, 19, Maruyama Shinmachi, Hongo, Tokio, Japan, Chemist (Imperial Japanese Navy).
 1906. Iddings, Richard P., Arlington Mills, Lawrence, Mass., U.S.A., Chemist.
 1885. Idris, T. H. W., M.P., 120, Pratt Street, Camden Town, N.W., Mineral Water Manufacturer.
 1902. Ihart, John P., 373, West 35th Street, New York City, U.S.A., Technical Chemist.
 1900. Imrie, John, 83, Horndean Road, Firth Park, Sheffield, Producer Gas and By-Products Plant Manager.
 1900. Ingalls, Walter R., (Communications) 505, Pearl Street, New York City; and (Journals) Bement Avenue, West New Brighton, Staten Is., N.Y., U.S.A., Mining Engineer and Metallurgist.
 1889. Ingle, Dr. Harry, Creskeld, Balwearie Road, Kirkcaldy, Fifehire, Organic Chemist.
 1891. Ingle, Herbert, 33, City Road, Edgbaston, Birmingham, Agricultural Chemist.
 1909. Ingleby, G. W., c/o John L. Seaton & Co., Ltd., Sculcoates, Hull, Director.
 1906. Inglis, Dr. Jno. K. H., University College, Reading, Berks., Lecturer.
 1884. Inglis, R. A., Culrain, Bothwell, N.B., Analytical Chemist.
 1900. Innes, R. Faraday, 4, Beech Terrace, Tarbock Road, Huyton, near Liverpool, Chemist.
 1906. Innes, Dr. W. Ross, 6, Griffiths Road, Wimbledon, S.W., Chemist.
 1904. Irlam, H. A., Long View Villa, Hitchin Road, Luton, Beds., Manager and Chemist.
 1884. Irving, J. M., 17A, Dickinson Street, Cooper Street, Manchester, Chemical Merchant.
 1906. Irwin, John T., Cledford, Middlewich, Cheshire, Manufacturing Chemist.
 O.M. Irwin, W., Inglehurst, Stand, near Manchester, Analytical Chemist.
 1893. Isaac, J. F. V., Research Chemist.
 1901. Isakovics, Alois von, Synfleuer Scientific Laboratories, Monticello, N.Y., U.S.A., Manufacturing Chemist.
 1900. Ittner, Dr. Martin H., c/o Colgate and Co., Jersey City, N.J., U.S.A., Soap and Essential Oil Chemist.
 1908. Ives, Herbert, 125, Pearl Street, Boston, Mass., U.S.A., Manager (Dyestuffs, etc.).

J

1890. Jackman, E. J., 60, Belgrave Road, Hford, Essex, Technical Chemist.
 1898. Jackson, Alf. George, 65, Ann Street, Brisbane, Queensland, Electro-Chemical Engineer.
 1906. Jackson, Arthur A., 672, East 43rd Street, Chicago, Ill., U.S.A., Chemist.
 1903. Jackson, Dr. D. H., 95, Abbey Road, St. John's Wood, N.W., Chemist.
 O.M. Jackson, Edward, Ravens Clift, Oxford Road, Moseley, Birmingham, Alkali Works Inspector.
 1904. Jackson, Ernest W., 3, Leven Street, Salthum, Yorks., Analytical Chemist.
 1891. Jackson, F., Smedley Bridge Works, Cheetham, near Manchester, Bleacher and Dyer.
 1883. Jackson, Frederick, 14, Cross Street, Manchester, Laboratory Furnisher.
 1886. Jackson, John, 98, Dobbie's Loan, Glasgow, Lubricant Manufacturer.
 1901. Jackson, Percy G., c/o National Boiler and General Insurance Co., 22, St. Ann's Square, Manchester, Chemist.
 1800. Jackson, Saml., c/o Binny and Co., Madras, India, Analytical Chemist.
 1902. Jackson, Samuel, c/o Wm. Metcalf, Ltd., Church, near Accrington, Director (Tar Distillery).
 1898. Jackson, Thos., Thornton View, Clayton, Manchester, Chemical Manufacturer.
 1900. Jackson, Victor G., 21, Frankfort Road, Herne Hill, S.E., Chemist.
 1903. Jackson, Wm. D. N., 29, Woodbine Avenue, Wallsend-on-Tyne, Analytical Chemist.
 1900. Jackson, Dr. W. Hatchett, Radcliffe Library, Oxford, Librarian and Science Tutor (Keble College).
 1893. Jackson, Rt. Hon. W. L., F.R.S., *See* Allerton, Rt. Hon. Lord.
 1899. Jackson, W. Morton, c/o British Oxygen Co., Ltd., Great Marlborough Street, Manchester Manager.
 O.M. Jackson, W. P., Saxilby, near Lincoln, Chemical Works Manager.
 1901. Jacobsen, Rudolph C., 154, Lake Street, Chicago, Ill., U.S.A., Editor of "Hide and Leather."
 1900. Jacoby, Areli H., c/o American Dyewood Co., 84, William Street, New York City, U.S.A., Chemist.
 1897. Jacqué, Manrice, "La Cantabrica," Galdacano, cerca Bilbao, Spain, Chemical Engineer.
 1901. Jadhava, Khasberao B., Nausari, Bombay, India, Collector and District Magistrate.
 1900. Jäger, B. M., c/o Geo. Jäger and Sons, 77, Burlington Street, Liverpool, Sugar Chemist.
 1886. Jago, Wm., 1, Garden Court, Temple, London, E.C., Barrister-at-Law.
 1883. James, E. T., British Alizarin Co., Ltd., Silvertown, Victoria Docks, E., Secretary.
 1885. James, Dr. J. Wm., Aylmer House, Weston-super-Mare; and (Journals) 29, Redcliffe Street, Bristol, Chemical Lecturer.
 1893. James, Lawrence S., 32, Hawley Street, Boston, Mass., U.S.A., Gas Inspector.
 1905. James, Oscar S., 227, George Street, Toronto, Canada, Analytical Chemist.
 O.M. Japp, Dr. F. R., F.R.S., The University, Aberdeen, Professor of Chemistry.
 1906. Jardine, S., Dallyn, Jardine, & Co., 23, Scott Street, Toronto, Canada, Chemical Merchant.
 1890. Jarmain, Geo. S., Dalton Lodge, Huddersfield, Wool Extractor.
 O.M. Jarmay, G., Hartford Lodge, Hartford, Cheshire, Alkali Manufacturer.
 1900. Jarvie, Jas., Ferndale, Kennmure Ave., Bishopbriggs, N.B., Chemist.
 1907. Jatar, S. B., 219, Upper Brook Street, C. on M., Manchester, Student.
 O.M. Jayne, Dr. H. W., c/o Barrett Manufacturing Co., Frankford, Philadelphia, Pa., U.S.A., Manufacturing Chemist.
 1908. Jeffery, John H., 10, Daysbrook Road, Streatham Hill, London, S.W., Chemist and Metallurgist.
 O.M. Jekyll, J., Castle Moat House, Lincoln, Chemical Manufacturer.
 1892. Jenkin, W. A., 5, Bella Vista, Minas de Rio Tinto, Provincia de Huelva, Spain, Metallurgical Chemist.
 1905. Jenkins, Chas. D., 8, Grove Street, Winchester, Mass., U.S.A., Chemist.
 1894. Jenkins, John H. B., Laboratory, G.E.R. Works, Stratford, E., Analytical Chemist.
 1894. Jenks, Robt. L., Kasauli, Punjab, India, Chemist.
 1908. Jennison, George, Derby House, Heaton Chapel, Stockport, Chemist.
 1905. Jennison, Jas., Mountfield, London Road, Greenhithe, Kent, Chemist.
 1907. Jensen, Chas. W. L., "Lauriston," Grand Avenue, Southbourne, Bournemouth, Brewer and Maltster.
 1904. Jepson, John Elliott, Star House, Feniscowles, near Blackburn, Chemist.
 1899. Jordan, Dr. David S., Temora, Colinton, Midlothian, Chemist (Gelatin Works).
 1899. Jessop, Louis V., Holmlea, Woodville Road, Leytonstone, Essex, Chemist.
 1904. Jewson, F. T., Earith, near St. Ives, Hunts., Chemist.
 1896. Job, Robt., Ambler, Pa., U.S.A., Analytical Chemist.

1906. John, David, Haileybury, Ontario, Canada, Chemist.
 1908. Johnson, Arthur, 2, Maple Street, Nursery Street, Pendleton, Manchester, Chemist.
 1886. Johnson, A. E., Claremont, Lyndhurst Road, Wolverhampton, Analytical Chemist.
 1904. Johnson, Cedric, Field House, Winnington, Northwich, Chemical Engineer.
 1906. Johnson, Chas. C., Tunstall Bay, *via* Vancouver, B.C., Canada, Chemical Engineer.
 1905. Johnson, Chas. F., Avery Chemical Co., Littleton, Mass., U.S.A., Superintendent.
 1891. Johnson, Edmond E., The Gales, Roding Lane, Woodford Bridge, Essex, Chemical Engineer.
 1900. Johnson, Edw., c/o Herdeiros Bowman, Ltd., Caixa 57, Pernambuco, Brazil, Sugar Works Manager.
 1908. Johnson, Dr. Edw. S., c/o Solvay Process Co., Syracuse, N.Y., U.S.A., Chemist.
 1902. Johnson, Emil F., 96-98, Maiden Lane, New York City, U.S.A., Consulting Chemist.
 1901. Johnson, Dr. F. M. G., 286, Peel Street, Montreal, Canada, Chemist.
 1904. Johnson, G. B., 7, Church Street, Liverpool, Wholesale Chemist.
 1906. Johnson, Dr. Harold, 5 and 6, Fowkes' Buildings, Great Tower Street, London, E.C., Chemist.
 1907. Johnson, H. Finnis, c/o Borax Consolidated, Ltd., 16, Eastcheap, London, E.C., Sales Manager.
 1908. Johnson, Horton, Ridgway, Pa., U.S.A., Tanner.
 O.M. Johnson, J. E., 40, Idmiston Road, Stratford, E., Manufacturing Chemist.
 1895. Johnson, Jesse F., Vaudreuil Station, P.Q., Canada, Chemical Engineer.
 1900. Johnson, John, c/o John Johnson and Co., 37th Street and Second Avenue, Brooklyn, N.Y., U.S.A., Chemical Engineer.
 1900. Johnson, Jno. W. H., York House, Thornhill, Dewsbury, and (Journals) West Riding Rivers Board, Wakefield, Yorks., Chemist.
 1906. Johnson, Oliver L., c/o The Aspinook Co., Jewett City, Conn., U.S.A., Dye Works Manager.
 O.M. Johnson, S. H., Warren Hill House, Loughton, Essex, Chemical Engineer.
 1904. Johnson, S. Hearon, 7, Church Street, Liverpool, Wholesale Chemist.
 1907. Johnson, Walter M., Box 376, Penns Grove, N.J., U.S.A., Chemist.
 1895. Johnston, Alex. R., 18, Percy Street, Ibrox, Glasgow, Analytical Chemist.
 1906. Johnston, A. McA., Box 108, Germiston, Transvaal, Metallurgical Chemist.
 1894. Johnston, G. Lawson. *See* Lawson-Johnston, G.
 1904. Johnston, J. H., 8, Leopold Road, Wimbledon, S.W., Chemist and Bacteriologist.
 1889. Johnston, Thos., Nobel's Explosives Co., Ltd., 195, West George Street, Glasgow, Manager.
 1904. Johnston, Thos. J., 4, Garrioch Drive, Maryhill, Glasgow, Chemist.
 1890. Johnston, Wm. A., The S. S. White Dental Manufacturing Co., Princess Bay, Staten Island, N.Y., U.S.A., Dental Enamel Manufacturer.
 1894. Johnston, W. E. Lawson. *See* Lawson-Johnston, W. E.
 O.M. Johnston, Wm. G., Anchor Chemical Works, 1005, Garngad Road, Glasgow, Technical Chemist.
 O.M. Johnstone, Jas., Shawfield Works, Rutherglen, Glasgow, Technical Chemist.
 1905. Johnstone, J. Swanston, National Distilleries Co., Bond Street, Durban, Natal, Distiller.
 1903. Johnstone, S. J., 15, Springfield Road, New Southgate, N., Research Chemist.
 O.M. Johnstone, W. G., Chemist.
 1907. Jolliffe, Ernest H., 16, Maitland Street, Toronto, Canada, Works Chemist.
 1905. Jolliffe, Frank, 27, Roseldine Street, Honor Oak Park, S.E., Chemist.
 1908. Jones, Andrew U., 334, Notre Dame Street West, Montreal, Canada, Mechanical Contractor.
 1904. Jones, Arthur B., Gardeng City, N.Y., & U.S.A., Superintendent.
 1902. Jones, David R., Standard Chemical Co., Deseronto, Ont., Canada, Chemical Engineer.
 1908. Jones, D. Trevor, c/o Brotherton and Co., Ltd., Litherland, Liverpool, Works Chemist.
 1902. Jones, E. Strangways, Sulphide Corporation, Ltd., Cockle Creek, N.S.W., Australia, Metallurgical Chemist.
 1909. Jones, E. Willis, Coleshill Terrace, Llanelly, South Wales, Chemical Manufacturer.
 O.M. Jones, E. W. T., 10, Victoria Street, Wolverhampton, Analytical Chemist.
 1897. Jones, Fred. W., 39, Pembury Road, Clapton, N.E., Technical Chemist.
 1896. Jones, G. Cecil, 41, London Road, Forest Hill, S.E., Consulting Chemist.
 1905. Jones, Harold, Morro Velho, Villa Nova de Lima, Minas Geraes, Brazil, Analyst and Assayer.
 O.M. Jones, H. Chapman, Royal College of Science, South Kensington, S.W., Senior Demonstrator in Chemistry.
 1907. Jones, Henry Williams, Earlsdon Lane, Styvechale Avenue, Coventry, Manufacturing Chemist.
 1893. Jones, Herbert. *See* Sefton-Jones, H.
 1901. Jones, Herbert J., c/o Brechfa Chemical Co., Ltd., Nantgareidig, R.S.O., South Wales, Chemist.
 1905. Jones, J. E. Stacey, Masonic Buildings, Coventry, Consulting Chemist and Metallurgist.
 1904. Jones, J. Shirley, Moscow, Idaho, U.S.A., Chemist.
 1899. Jones, Llewellyn J. W., Metallurgist.
 1894. Jones, M. W., The Cottage, Brislington, Bristol, Manager (Oil and Colour Works).
 1887. Jones, T. Tolley, Australian Explosives and Chemical Co., Ltd., 138, Queen Street, Melbourne, Victoria, Australia, Explosives Manufacturer.
 O.M. Jones, Walter Norris, Lancashire Metal Works, Widnes, Technical Chemist.
 1903. Jones, Wm. App., c/o Boston Artificial Leather Co., Metropolitan Building, New York City, U.S.A., Chemist.
 1905. Jones, W. Ellis, 80, Arundel Avenue, Liverpool, Sugar Refiner.
 1904. Jordan, Stanley, 100, William Street, New York City, U.S.A., Importer of Chemicals.
 1908. Joselin, Percy H., 81, Bennerley Road, New Wandsworth, S.W., Chemist.
 1905. Joseph, A. F., Ceylon Technical College, Colombo, Ceylon, Lecturer on Chemistry.
 1900. Josephson, Edgar, c/o Pantazote Leather Co., Passaic, N.J., U.S.A.
 1906. Joshua, Dr. Walter P., 45, Belsize Avenue, Hampstead, N.W., Chemist.
 1891. Joslin, Omar T., 3223, Spring Grove Avenue, Cincinnati, Ohio, U.S.A., Chemical Engineer.
 1887. Jouët, Dr. C. H., Roselle, Union Co., N.J., U.S.A., Technical Chemist.
 1889. Journaud, Louis, 8, Place St. Maurice, Vienne (Isère), France, Technical Chemist.
 1904. Jowett, Dr. H. A. D., Phoenix Mills, Dartford, Kent, Chemist.
 1903. Joyce, Clarence M., c/o Arlington Co., Arlington, N.J., U.S.A., Chemist.
 1887. Jürgensen, Dr. Rolof, Karlasse 5, Prag-Zizkov, Austria, Chemist.
 O.M. Justice, P. M., 55-56, Chancery Lane, London, W.C., Patent Agent.

K

1896. Kalbfleisch, Franklin H., Metropolis Building, Broadway and 16th Street, New York City, U.S.A., Chemical Manufacturer.
 1908. Kalenski, Edmund, 27, rue Cité Derrière, Lausanne, Switzerland, Chemist.
 1908. Kaliski, Dr. Maximilian S., 101, West 130th Street, New York City, U.S.A., Technical Chemist.
 1884. Kalle, Dr. Wm., Biebrich-am-Rhein, Germany, Colour Manufacturer.
 1901. Kauder, Dr. E., c/o Merck and Co., Rahway, N.J., U.S.A., Chemist.
 1903. Kauffman, Milton H., American Smelting and Refining Co., Durango, Colo., U.S.A., Chemist.
 1892. Kaufmann, Dr. Herbert M., c/o Mutual Chemical Co., Jersey City, N.J., U.S.A., Chemist.

1904. Kaus, Dr. Emil, c/o Roessler and Hasslacher Chemical Co., Perth Amboy, N.J., U.S.A., Chemist.
1904. Kawai, I., 54, Shirokane, Shiba, Tokyo, Japan, Chemist (Camphor Monopoly).
1885. Kawakita, Prof. Michitada, Imperial Engineering College, Tokio, Japan, Professor of Applied Chemistry.
- O.M. Kay, Wm. E., The Thorns, Prestwich Park, near Manchester, Printworks Chemist.
1905. Kaye, Frederick, 20, Birchwood Avenue, Muswell Hill, N., Research Chemist.
1904. Kaye, Thos., Westerfield, Perth, Scotland, Analytical Chemist.
1905. Kayser, Edwin Cuno, Chemist.
1884. Keane, Dr. Chas. A., Sir John Cass Technical Institute, Jewry Street, Aldgate, E.C., Principal.
- O.M. Kearns, H. W., Baxenden, near Accrington, Dyer.
1897. Kearns, Jno. S., Cowpe Mills, Waterfoot, near Manchester, Chemist and Dyer.
1894. Kebler, Lyman F., Department of Agriculture, Bureau of Chemistry, Washington, D.C., U.S.A., Chief of Drug Laboratory.
1908. Keeble, A. J., Wreham Hall, Stoke Ferry, Norfolk, Land Owner.
1908. Keiller, P. A., c/o Colombo Commercial Co., Ltd., Colombo, Ceylon, Agricultural Analyst.
1886. Keiser, Prof. E. H., Washington University, St. Louis, Mo., U.S.A., Professor of Chemistry.
1908. Keith, Jas. W., c/o C. Tennant and Co, Carnoustie, Forfarshire, Analytical Chemist.
1900. Kelf, Henry C., 51, Preston Road, Leytonstone, N. E., Sugar Chemist.
1907. Keller, Dr. Edward, P.O. Box 363, Perth Amboy, N.J., U.S.A., Chemist and Metallurgist.
1905. Keller, Robt. J., 88, Broad Street, Boston, Mass., U.S.A., Dyestuff and Chemical Merchant.
1885. Kellner, Dr. Wm., 135, Victoria Road, Old Charlton, S.E., Chemist to War Department.
1908. Kellogg, H. W., c/o National Electrolytic Co., Niagara Falls, N.Y., U.S.A., General Manager.
1908. Kemp, Edw. S., 131, Belvoir Street, Hull, Analyst.
1889. Kempson, John F., Pye Bridge Chemical Works, near Alfreton, Derbyshire, Chemical Manufacturer.
1907. Kendall, G. F., Chemical Works, Stratford-on-Avon, Chemical Manufacturer.
1901. Kennedy, Alex., Kennill House, Bothwell, N.B., Rosin Distiller.
1903. Kenyon, Percy S., Park House, Cheadle Hulme, Cheshire, Drysalter.
1889. Kenyon, Thos., The Shrubbery, Hilton Park, Prestwich, near Manchester, Manufacturing Chemist.
1906. Kepner, S. H., 149, 12th Street, Long Island City, N.Y., U.S.A., Superintendent.
1888. Ker, Alan D., 14, Wilton Mansions, Glasgow, Chemical Manufacturer.
1899. Kern, Walter P., 275, Lafayette Avenue, and (Journals) c/o General Chemical Co., Dundee Works, Passaic, N.J., U.S.A., Chemist.
1906. Kerr, Charles H., 70, West 10th Avenue, Columbus, Ohio, U.S.A., Ceramic Engineer (Carborundum Co.).
1890. Kerr, Saml. T., 516, North Delaware Avenue, Philadelphia, Pa., U.S.A., Salt Manufacturer.
1897. Kerr, Wm. M., c/o General Chemical Co., 608, Philadelphia Bourse, Philadelphia, Pa., U.S.A., Manufacturing Chemist.
1896. Kershaw, Jno. B. C., West Lancashire Laboratory, Waterloo, Liverpool, Analytical Chemist.
1902. Kessler, Henry W., 317, Electric Building, Cleveland, Ohio, U.S.A., Manufacturing Chemist.
1903. Kessler, Raphael, Pittston, Pa., U.S.A., Chemical Manager.
1893. Kestner, Paul, 7, Rue de Toul, Lille, France, Chemist.
1898. Keswick, Wm., M.P., 3, Lombard Street, London, E.C., Merchant.
1900. Kewley, Jas., Arbory Road, Castletown, Isle of Man, and (Journals) Balik Papan, Dutch Borneo, Technical Chemist.
1890. Keys, W. H., Hall End Works, West Bromwich, Oil and Chemical Manufacturer.
1892. Kibble, W. Oakes, Charlotte, N.C., U.S.A., Chemical Engineer.
1900. Kilgore, Benj. W., Raleigh, N.C., U.S.A., Chemist.
1901. Kilmer, Fred. B., c/o Messrs. Johnson and Johnson, New Brunswick, N.J., U.S.A., Chemical Manufacturer.
1905. Kimball, Herbert S., 46, Cornhill, Boston, Mass., U.S.A., Mill Engineer.
- O.M. Kinch, E., Royal Agricultural College, Cirencester, Professor of Chemistry.
1905. King, Capt. Alex. E., R.A., Egyptian Army Citadel, Cairo, Egypt, and (Journals) c/o Cox & Co., 16, Charing Cross, London, W.C., Inspector of Explosives.
- O.M. King, A. J., M.P., (Journals) Ingersley Vale, and (communications) Rock Bank, Bollington, near Macclesfield, Bleacher and Finisher.
1907. King, C. A., c/o The Farnley Iron Co., Farnley, near Leeds, Technical Chemist.
1884. King, Col. C. M., Campsie Alum Works, Lennoxtown, N.B., Alum Manufacturer.
1905. King, Frank E., 75, Gracechurch Street, London, E.C., Analytical Chemist.
- O.M. King, J. Falconer, 30, Chambers Street, Edinburgh, Consulting Chemist.
1887. King, Col. Robt., 115, Wellington Street, Glasgow, Chemical Manufacturer.
1907. King, Robt. J., c/o Merrimac Chemical Co., North Woburn, Mass., U.S.A., Chemist.
1895. King, Sidney J., Hazeldene, Avenue Road, Bexley Heath, Kent, Colour and Dyestuff Traveller.
- O.M. King, Walter R., 16, Mincing Lane, London, E.C., and (Journals) Holford Lodge, Trinity Avenue, Southend-on-Sea, Chemical Manufacturer.
1905. King, Warren C., c/o General Chemical Co., 25, Broad Street, New York City, U.S.A., Salesman.
1903. King, William, South Coast Junction, Natal, S. Africa, Analytical Chemist.
1896. Kingdon, Holman, c/o Joseph Crosfield and Sons, Warrington, Technical Chemist.
1908. Kingsbury, Percy C., c/o S. Pearson and Son, Ltd., Minatitlan, Mexico, Civil Engineer.
1883. Kingsford, T. P., Oswego, N.Y., U.S.A., Starch Manufacturer.
- O.M. Kingzett, C. T., Newlands, St. George's Avenue, Weybridge, Surrey, and (Journals) Sanitas Co., Ltd., Locksley Street, Limehouse, E., Technical Chemist.
1906. Kinnertley, H. W., Branscombe, Merry Hill Road, Bushey, Herts, Chemist and Manufacturer.
1892. Kinnicutt, Professor L. P., 77, Elm Street, Worcester, Mass., U.S.A., Professor of Chemistry (Worcester Polytechnic Institute).
1897. Kipping, Dr. F. Stanley, F.R.S., University College, Nottingham, Prof. of Chemistry.
1908. Kirkhope, T. Bertram, c/o Mrs. Wade, Connor-downs, Hayle, Cornwall, Explosives Works Chemist.
1898. Kirkland, Archd., 78, High Street, Irvine, N.B., Baker.
1905. Kirkland, John, 105, Holmdene Avenue, Herne Hill, S.E., Technical Instructor.
1897. Kirkland, Robt., Hawthorne, Newmains, Lanarkshire, N.B., Chemist.
1900. Kirkpatrick, Prof. Stafford F., 24, Frontenac Street, Kingston, Ont., Canada, Professor of Metallurgy.
1902. Kitchen, Wm. J., Port Melbourne North, Vic., Australia, Soap and Candle Manufacturer.
1891. Kitson, Rt. Hon. Sir James, Bart., M.P. See Airedale, Lord.
1883. Kitto, B., 26, Lancaster Road, Finsbury Park, London, N., Analytical Chemist.
1900. Kittredge, H. G., c/o The Kay and Ess Co., Dayton, Ohio, U.S.A., Chemist.
1908. Klaber, Wm., c/o Castle Kid Co., Camden, N.J., U.S.A., Chemist.
1900. Kleber, Dr. Clemens, Union Avenue, Clifton, N.J., U.S.A., Director (Fritzsche Bros.' Laboratory).

1888. Kleemann, Dr. S., Farben Fabrik, Forehheim, Bavaria, Analytical Chemist.
1908. Klein, Friedrich, 762, Melrose Avenue, New York City, U.S.A., Chemist.
1908. Klein, John Shorkley, Floral Park, Long Island, N.Y., U.S.A., Chemist.
1909. Klemm, Wilfred E., 25, Marmion Road, Liverpool, S., Chemist.
1908. Klien, Dr. J. L., c/o Celluloid, Ltd., Port Talbot, South Wales, Works Manager.
1903. Kline, Clarence M., 429, Arch Street, Philadelphia, Pa., U.S.A., Wholesale Druggist.
1889. Klipstein, A., 122, Pearl Street, New York City, U.S.A., Chemical Manufacturer.
1902. Klipstein, Ernest C., 116, Prospect Street, East Orange, N.J., U.S.A., Chemical Manufacturer.
1891. Knaggs, Alfred B., 2, Bradley Lane, Huddersfield, Technical Chemist in Dyeworks.
1905. Knapp, Sewell A., 1243, Myrtle Street, Oakland, Cal., U.S.A., Mine Manager.
1892. Knecht, Dr. E., Beech Mount, Marple, Cheshire, Professor of Tinctorial Chemistry.
1904. Kniffen, Frederick, c/o International Smokeless Powder Co., Berlin, N.J., U.S.A., Chemist.
1887. Knight, A. H., Derrynin, Talbot Road, Oxtou, Cheshire, Assayer.
1903. Knight, Harley F., 61, Amhurst Park, Stamford Hill, N., Analyst.
1884. Knight, Henry, Stanley House, 73, Anfield Road, Liverpool, Colour and Varnish Manufacturer.
- O.M. Knight, J. Baillie, Royal Primrose Soapworks, Silvertown, London, E., Soap Manufacturer.
1907. Knight, J. Burnett, St. Lawrence Work, Uphall Road, Hford, Works Manager and Chemist.
1887. Knights, J. West, Public Laboratory, Tenison Road, Cambridge, Analytical Chemist.
1885. Knipler, F., c/o R. Harper and Co., Port Melbourne, Victoria, Australia, Starch Manufacturer.
1907. Knoedler, E. L., c/o Welsbach Co., Gloucester City, N.J., U.S.A., Factory Foreman.
1883. Knowles, Joshua, Stormer Hill, Tottington, near Bury, Calico Printer.
1904. Knowles, W. R., The Hollies, Wood Green, Wednesbury, Chemical Works Manager.
1908. Knox, Arthur A., The Cottage, Glenboig, N.B., Chemist (Fireclay Works).
1886. Knox, E. W., Colonial Sugar Refining Co., Sydney, N.S.W.; and (subs.), c/o Parbury, Henty and Co., 20, Eastcheap, London, E.C., Sugar Manufacturer and Refiner.
1906. Knudsen, Kristian Hv., 1095, Lincoln Place, Brooklyn, N.Y., U.S.A., Chemist.
1905. Koch, Geo. W., Lock Box 12, Woodhaven, Long Is., N.Y., U.S.A., Chemist.
1904. Koch, J. A., Bluff and Pride Streets, Pittsburg, Pa., U.S.A., Chemist.
1904. Koebig, Dr. J., 411, South Main Street, Los Angeles, Cal., U.S.A., Chemical Engineer.
1909. Koekkoek, Patrick R., 29, Gwendwr Road, West Kensington, W., Works Chemist.
1904. Koerner, H. Theo., Beyerstrasse 28, Chemnitz, Germany, Student of Chemistry.
1884. Kohn, Dr. Charles A., See Keane, Dr. Chas. A.
1902. Kolmstamm, Lothair S., 87, Park Place, New York City, U.S.A., Chemist.
1908. Kotibhaskar, A. S., c/o The Alambic Chemical Works Co., Ltd., 68, Shamshet Street, Market, Bombay, India, Chemist and Managing Agent.
- O.M. Kraftmeier, E., 54, Parliament Street, Westminster, S.W., Explosives Manufacturer.
1906. Kraus, Dr. Paul, 69, Nauderstrasse, Tübingen, Germany, Chemist.
1894. Krause, Dr. Albert H., 1444, West 98th Street, Cleveland, Ohio, U.S.A., Chemist (Grasselli Chemical Co.).
- O.M. Krause, Prof. Dr. G., Cöthen (Anhalt), Germany, Chemist.
- O.M. Krause, O. H., c/o American Sugar Refining Co., Jersey City, N.J., U.S.A., Chemical Engineer.
1898. Krebs, H. J., 806, Franklin Street, Wilmington, Del., U.S.A., Manufacturing Chemist.
1900. Kremers, Dr. Edw., Madison, Wis., U.S.A., Professor (University of Wisconsin).
1906. Kremers, William, Holland, Mich., U.S.A., Sugar Mill Superintendent.
1908. Kress, Otto, 438, West 116th Street, New York City, U.S.A., Teacher of Science.
1907. Kuan, C. H., 3332, Walnut Street, Philadelphia, Pa., U.S.A., Chemist.
1904. Kübler, Alfred, 69, Barclay Street, New York City, U.S.A., Vice-President, Geigy Aniline and Extract Co.
- O.M. Kühl, W. H., 82, Königgrätzerstrasse, Berlin, S.W. XI., Germany, Bookseller.
1900. Kunheim, Dr. Erich, 32, Dorotheenstrasse, Berlin, N.W., Germany, Chemist.
1904. Kunz, Dr. George F., c/o Tiffany and Co., 37th Street and 5th Avenue, New York City, U.S.A., Gem Expert.
1905. Kurt, Franklin T., 458, Boylston Street, Boston, Mass., U.S.A., Professor of Chemistry, B.Y.M.C.A.
1907. Kutsch, Dr. Wm. A., c/o Corn Products Manufacturing Co., Pekin, Ill., U.S.A., Chemist.
1900. Kuttroff, Fred., 128, Duane Street, New York City, U.S.A., Merchant.
- O.M. Kynaston, J. W., 3, Oak Terrace, Beech Street, Liverpool, Chemical Engineer.
1907. Kynaston, Wm. C. R., 9, Harland Road, Higher Tranmere, Birkenhead, Analyst.

L

1897. Labonde, Dr. Leon, 3418, South Flower Street, Los Angeles, Cal., U.S.A., Consulting Chemical Engineer.
1906. Lacey, Harold G., Ardoch, Nether Street, Finchley, N., Chemist.
1890. Lacey, E. C., St. Julian's Lodge, St. Julian's Farm Road, West Norwood, Manufacturing Chemist.
1903. Lachman, Dr. Arthur, 3037, Wheeler Street, Berkeley, Cal., U.S.A., Chemical Engineer.
- O.M. Laidler, C. P., 20, Noble Terrace, Gateshead-on-Tyne, Analytical Chemist.
- O.M. Lake, G., jun., Lee Mount, Glossop, Derbyshire, Analytical Chemist.
1907. Lake, Henry B., Laboratory, Canadian Pacific Railway Co., Winnipeg, Canada, Chemical Engineer.
1900. Lamar, Wm. R., 5656, Clemens Avenue, St. Louis, Mo., U.S.A., Chemist.
1898. Lamb, Morris Chas., 12, Coleraine Road, Westcombe Park, Blackheath, S.E., Chemist.
1900. Lambert, Walter S., Park Road, Clydach, R.S.O., Glamorgan, Analyst.
1907. Lancaster, Harry M., Faculty of Applied Science, The University, Toronto, Canada, Chemist.
1904. Lancey, Darragh de, c/o Waterbury Buckle Co., Waterbury, Conn., U.S.A., Secretary.
1904. Lane, C. Cyril P., c/o The Avon India-Rubber Co., Melksham, Wilts., Chemist.
1903. Lane, Nathaniel J., U.S. Laboratory, 641, Washington Street, New York City, U.S.A., Chemist.
1893. Lang, Dr. Wm. R., University of Toronto, Canada, Professor of Chemistry.
- O.M. Langdon, Dr. M. J., c/o Coheco Manufacturing Co., Dover, N.H., U.S.A., Analytical Chemist.
1892. Langer, Dr. Carl, Yunspenllweh, Clydach, R.S.O., Glamorganshire, Analytical Chemist.
1897. Langmuir, Arthur C., c/o Marx and Rawolle, 9, Van Brunt Street, Brooklyn, N.Y., U.S.A., Factory Manager.
1902. Langmuir, F. Leighton, 350, Bloor Street West, Toronto, Canada, Chemist.
1898. Langstaff, Wm., Grasselli, N.J., U.S.A., Chemist.
1900. Lant, Herbert, "Ivy Bank," Wath-on-Dearne, near Rotherham, Yorks., Chemist and Manager.
1906. Lantz, Alfred, 115, Rue des Poissoniers, St. Denis sur Seine, France, Colour Works Manager.
1903. Larter, Alfred T., 86, Inderwick Road, Stroud Green, N., Chemist.

1907. Lasché, Prof. Alfred, The Lasché Institute, 2809, Vine Street, Milwaukee, Wis., U.S.A., Chemist and Bacteriologist.
1904. Lasher, F. G., 34, Bowne Street, Brooklyn, N.Y., U.S.A., Chemist.
1884. Latham, Baldwin, Parliament Mansions, Victoria Street, Westminster, S.W., Civil Engineer.
1889. Latham, J. J., Mill House, Bold, Widnes, Chemical Works Manager.
1907. Lathwood, Arthur, c/o Borax Consolidated, Ltd., 16, Eastcheap, London, E.C., Chemist.
1908. Lauder, A. Gilbert, c/o Nelson and Lauder, O'Neil Building, Binghampton, N.Y., U.S.A., Consulting Chemist.
1901. Law, Herbert, 72, Belyedere Road, Liscaud, Cheshire, Analytical Chemist.
1907. La Wall, Chas. H., 39, South 10th Street, Philadelphia, Pa., U.S.A., Analytical Chemist.
1907. Lawrence, James, c/o W. T. Glover and Co., Trafford Park, Manchester, Chemist.
- O.M. Lawrence, Jas., Box 737, Joplin, Mo., U.S.A., Explosives Manufacturer.
1904. Lawson, Jos. H. S., Britannia Mills, Hulme, Manchester, Salesman.
1900. Lawson, Wm. L., c/o Great Western Sugar Co., Sterling, Colo., U.S.A., Chemist.
1894. Lawson-Johnston, G., (Journals) 29, Portman Square, W., and 15, George Street, Mansion House, London, E.C., Vice-Chairman.
1894. Lawson-Johnston, W. E., c/o Bovril, Ltd., 152, Old Street, London, E.C., Director.
1893. Lawton, Thos., Perry Villa, Perry Bar, Birmingham, Chemical Works Manager.
1890. Laycock, Dr. W. F., 46, Boar Lane, Leeds, Analytical Chemist.
1907. Leach, Dr. F. P., Claremont, Penns Lane, Erdington, Warwickshire, Research Chemist.
1907. Leach, Paul F., c/o Lactic Process Co., Room 309, 100, William Street, New York City, U.S.A., Secretary.
1908. Leake, Percy C., 8, St. Onihbert's Terrace, Ferryhill Village, Co. Durham, Tar Works Manager.
1898. Lean, Geo., 15, Park Terrace, Glasgow, Chemist.
1897. Leathart, Thos. H., c/o Locke, Blackett and Co., Ltd., Lead Works, Newcastle-on-Tyne, Lead Manufacturer.
- O.M. Leather, Dr. J. Walter, Agricultural Research Institute, Pusa, Bengal, India, Government Chemist.
1893. Le Bouillier, Clement, c/o Taylor Iron and Steel Co., High Bridge, N.J., U.S.A., Chemist.
1907. Lecco, Prof. Marco T., Belgrade, Servia, Professor of Chemistry.
1904. Le Chatelier, Prof. H., 75, Rue Notre Dame des Champs, Paris, France, Professor (l'Ecole des Mines).
1896. Lecomber, W. G., Cambridge Works, Knott Mill, Manchester, Engineer.
1896. Lederle, Dr. E. J., 39, West 38th Street, New York City, U.S.A., Chief Chemist.
1892. Ledoff, Prof. A., Technological Institute, Kharkoff, Russia, Professor of Chemistry.
1895. Ledoux, Dr. Albert R., 99, John Street, New York City, U.S.A., Chemist.
1903. Ledoux, Aug. D., 15, William Street, New York City, U.S.A., Importer of Pyrites.
1905. Lee, Ashton, Lawrence, Mass., U.S.A., Manufacturing Chemist.
1905. Lee, Frank W., Lawrence, Mass., U.S.A., Manufacturing Chemist.
1905. Lee, John C., Mountford Street, Brookline, Mass., U.S.A., Assistant Engineer (American Telegraph and Telephone Co.).
1898. Lee, Jno. L., Woodfield, Lytham, Lancashire, Dyer and Bleacher.
1885. Lee, S. Wright, 6-10, Whitechapel, Liverpool, Wholesale Druggist.
1906. Lee, William, 28, Sherard Gardens, Eltham, Kent, Works Chemist.
1903. Leerburger, Henry, 54, Beckman Street, New York City, U.S.A., Essential Oil Merchant.
1903. Leese, Jos., junr., 3, Ash Grove, Victoria Park, Manchester, Analytical and Technical Chemist.
1901. Lefebvre, Georges, Compagnie du Phospho-Guano, 27, Rue La Rochefoucauld, Paris, Director.
1901. Leffler, Rudolf L., c/o Thos. Firth and Sons, Ltd., Norfolk Works, Sheffield, Metallurgical Chemist.
1907. Lehmann, Dr. Adolf, Department of Agriculture, Bangalore, India, Agricultural Chemist.
1908. Lehmann, Xavier M., c/o F. E. Atteaux and Co., 176, Purchase Street, Boston, Mass., U.S.A., Textile Chemist.
1888. Leigh, Cecil, Birmingham Metal and Munition Co., Adderley Park Rolling Mills, Birmingham, Technical Chemist.
1906. Leigh, Edw. Collier, Caixa 147, Pernambuco, Brazil, Gas Works Manager.
1902. Leighton, A. E., Cordite Factory, Aruvankad, Nilgiris, India, Analytical Chemist.
1907. Leisel, Julius, Box 867, Greensboro, N.C., U.S.A.
1894. Leitch, Jno. W., Milnsbridge Chemical Works, near Huddersfield, Aniline Dye Manufacturer.
1904. Le Maistre, Fred J., Room 727, Du Pont Building, Wilmington, Del., U.S.A., Research Chemist.
1898. Lemau, Wm. T., P.O. Box 900, St. Louis, Mo., U.S.A., Oil and Asphalt Agent.
1908. Lemeland, Dr. P., 8, Rue Alfred de Vigny, Paris, France, Chemist.
1901. Lengfeld, Dr. Felix, 1804, Fillmore Street, San Francisco, Cal., U.S.A., Manufacturing Chemist.
1883. Lennard, F., Ilford Manor House, near Lewes, Sussex, Chemical Manufacturer.
1884. Leonard, Wm. J., 1, Lindfield Gardens, Hampstead, N.W., Naphtha Distiller.
1903. Lepsius, Prof. Dr. B., Griesheim a. M., Germany, Director (Chem. Fabr. Griesheim-Elektron).
1888. Lequin, E., Directeur Général des Usines de Produits Chimiques de la Société de St. Gobain, 1, Place des Saussaies, Paris (VIII^e), France.
1904. Leslev, R. W., 604, Pennsylvania Building, Philadelphia, Pa., U.S.A., Cement Manufacturer.
1907. Leslie, Fred. A., College of Pharmacy, 115, West 68th Street, New York City, U.S.A., Assistant Chemist.
1894. Leslie, Hugh M., Marikuppam, Mysore State, South India, Chemical Engineer.
1904. Lessing, Dr. Rudolf, Southampton House, 317, High Holborn, London, W.C., Consulting Chemist.
1900. Lessner, Chas. B., Carrill, Spain, Metallurgical Chemist.
1892. Lester, J. H., Royal Exchange, Manchester, Analytical Chemist.
1899. Le Sueur, Dr. Henry R., Chemical Laboratory, St. Thomas' Hospital, London, S.E., Demonstrator.
1891. Lever, Wm. H., M.P., Thornton House, Thornton Hough, Cheshire, Soap Manufacturer.
1901. Levett, Walter, Holmlands, Stanford-le-Hope; and (Journals) Mines Safety Explosives Co., Stanford-le-Hope, Essex, Factory Manager.
1903. Levi, Dr. Louis E., c/o Pfister and Vogel Leather Co., Milwaukee, Wis., U.S.A., Chemist.
1906. Levinstein, Edgar, 74, India Street, Boston, Mass., U.S.A., Chemical Manufacturer.
1901. Levinstein, Dr. Herbert, Hawkesmoor, Wilbraham Road, Fallowfield, Manchester, Chemist.
- O.M. Levinstein, Ivan, Hawkesmoor, Fallowfield, Manchester, Colour Manufacturer.
1903. Levy, Arthur G., 45, Clifton Hill, Abbey Road, London, N.W., Chemist.
1901. Levy-Mond, Dr. Albert, *See* Mond, Dr. Albert L.
1905. Lévy, René J., 2, Nether-ton Road, St. Margarets-on-Thames, Managing Director (British Liquid Air Co.).
1887. Lewes, Prof. Vivian B., Royal Naval College, Greenwich, S.E., Professor of Chemistry.
1898. Lewin, H. James, Royal Clarence Yard, Gosport, Hants, Analytical Chemist.
1896. Lewis, Daniel C., c/o Millville Manufacturing Co., Millville, N.J., U.S.A., Dye Works Chemist.

1904. Lewis, Edw. W., c/o J. G. Ingram and Sons, London India Rubber Works, Hackney Wick, S.E., Chemist.
1900. Lewis, Ernest A., 310, Dudley Road, Birmingham, Chemist and Metallurgist.
1905. Lewis, F. W., Aetna Powder Co., 143, Dearborn Street, Chicago, Ill., U.S.A., Secretary.
1900. Lewis, John, 35, Mundania Road, Honor Oak, S.E., Cashier (Paint Works).
1900. Lewis, S. Judd, 122, Newington Causeway, London, S.E., Analytical Chemist.
1889. Lewkowitsch, Dr. Julius, 71, Priory Road, West Hampstead N.W., Consulting Chemist.
1907. Leyson, Lewis T., Pencynor, near Neath, South Wales, Analytical Chemist.
1901. Lichtenstein, Alf. F., c/o Geisenheimer and Co., P.O. Box 994, New York City, U.S.A., Chemist.
- O.M. Lichtenstein, Theodore, Chemical Works, Silvertown, E., Manufacturing Chemist.
1904. Lichtenthaler, Robt. A., Agricultural Experiment Station, State College, Pa., U.S.A., Chemist.
1892. Liddle, G. A., George Hotel, Castletown, Isle of Man, Chemist, Dyewood Extract Works.
1885. Liddle, W. T., 14, Willows Avenue, Ansdell, Lytham, Chemist and Manager.
1904. Lieber, Hugo, 1, Platt Street, New York City, U.S.A., Chemist.
- O.M. Liebmann, Dr. A., 16, Darby Avenue, West Didsbury, Manchester, Analytical Chemist.
- O.M. Lightfoot, T. E., Fernleigh, Acerrington, Calico Printer's Chemist.
1905. Liley, Thos. A., 37, Aston Road, Bramley, Leeds, Chemist.
1898. Lilly, Josiah K., c/o Eli Lilly and Co., Indianapolis, Ind., U.S.A., Manufacturing Pharmacist.
1885. Lilly, Oliver M., The Croft, Spondon, Derby, Colour Manufacturer.
1904. Lindemann, Ottocar, 53, Victoria Street, Westminster, S.W., Managing Director (Korting Bros., Ltd.).
1906. Linder, S. E., Leodholt, The Drive, Buckhurst Hill, Essex, Analytical Chemist.
1908. Lindfield, James H., 107, Putney Bridge Road, Putney, S.W., Technical Chemist.
1903. Lindmueller, C., c/o United Zinc and Chem. Co., Argentine, Kansas, U.S.A., Chemist.
1897. Lindsay, Robt., Heidelberg Roodepoort, Greylingstad, Transvaal, Chemist.
1890. Ling, Arthur R., Laboratory, 74, Great Tower Street, London, E.C., Consulting Chemist.
1908. Linthicum, J. Francis, c/o The Spanish-American Iron Co., Felton, Oriente, Cuba, Chemist.
1901. Lippencott, Warren B., 345, Lafayette Street, Denver, Colo., U.S.A., Chemist.
1905. Lips, Dr. Carl H., 99, Hart Street, Brooklyn, N.Y., U.S.A., Chemist.
1896. Lishman, Geo. P., Bunker Hill, Fence Houses, Co. Durham, Colliery Chemist.
1905. Little, Arthur D., 93, Broad Street, Boston, Mass., U.S.A., Consulting Chemist.
1901. Little, C. A., Elyria, Ohio, U.S.A., Analytical Chemist.
1889. Little, Wm. G., Blendon Grove, Bexley, Kent, Chemical Manufacturer.
- O.M. Littlejohn, Jas., c/o Littlejohn and Whitby, P.O. Box 849, Johannesburg, Transvaal, Analytical Chemist.
1904. Livermore, W. D., Washington Mill, Lawrence, Mass., U.S.A., Chemist.
1886. Liversedge, A. J., Strathgryfe, Kilmaleolm, N.B., Mechanical Engineer.
1906. Liversedge, S. G., City Laboratory, Castle Street, Dublin, Ireland, Analytical Chemist.
1901. Liversedge, J. F., Council House, Birmingham, Public Analyst.
- O.M. Liversidge, Prof. A., F.R.S., c/o Young J. Pentland, 21, Warwick Lane, London, E.C., Professor of Chemistry.
1907. Liversidge, Bernard, Rossholme, Clifton Lane, Rotherham, Yorks., Analytical Chemist.
1883. Livingston, W. J., London County Council, Spring Gardens, London, S.W., Analytical Chemist.
1903. Llewellyn, Ivor P., Goole Alum Works, Goole, Chemist.
1907. Llewellyn, W. B., Rock Villa, New Hey, near Rochdale, Chemist.
1899. Lloyd, Charles, (subscriptions) c/o Lake View Consols, Ltd., Salisbury House, London, E.C.; and (Journals) c/o Manager, Lake View Consols, Ltd., P.O. Box 99, Finistoun, West Australia, Secretary.
1909. Lloyd, Edward, 27, Broomgrove Road, Sheffield, Chemical Engineer.
1901. Lloyd, Leonard B., Broadford Tannery, Broadford, Victoria, Australia, Tanner.
1907. Lloyd, Dr. Lorenzo L., Technical College, Bradford, Yorks., Lecturer in Chemistry.
1908. Lloyd, Capt. M. B., 3, Neville Terrace, Onslow Gardens, London, S.W., Director of Curtis's and Harvey, Ltd.
1900. Lloyd, Thos. H., c/o Quibell Bros., Newark, Analyst.
1906. Lloyd-Wiley, W. S., 5, Cottage Grove, Bow, E., Charcoal Manufacturer.
1909. Lobley, Alfred G., Lamp Department Laboratory, The Edison Swan U.E.L. Co., Ltd., Ponders End, Middlesex, Works Chemist.
1888. Lodge, Edw., 25, Seale Hill, Cowcliffe, Huddersfield, Teacher of Wool Dyeing.
1900. Loeb, Dr. Morris, 273, Madison Avenue, New York City, U.S.A., Professor of Chemistry.
1891. Loewenthal, Dr. R., Uhlendstrasse 39, Frankfurt a/M., Germany, Lecturer on Dyeing.
1905. Lomax, Abraham, 83, Station Road, Kearsley, Farnworth, R.S.O., Potter's Chemist.
1907. Lomax, Ernest L., Apartado 116, Minatitlan, Estado de Vera Cruz, Mexico, Chemist.
1901. Long, Eugene J., c/o E. O'Callaghan and Son, City Tannery, Limerick, Ireland, Tanner.
1898. Longstaff, Jas. P., Chemical Department, The University, Edinburgh, Assistant.
1908. Longwell, Alex., 37, Melinda Street, Toronto, Canada, Mining Engineer.
1902. Loomis, Henry M., U.S. Food Laboratory, 445, Arcade Annex Building, Seattle, Wash., U.S.A., Chemist.
1904. Loomis, Dr. Horatio, 58, West 40th Street, New York City, U.S.A.
1890. Lord, F. J., Winmarleigh, Southbourne, Christchurch, Hants., Analytical Chemist.
1896. Lord, Jno. Lloyd, 23, Park View, Elton, Bury, Lancs., Chemist and Manager.
1897. Lord, N. W., 338, West 8th Avenue, Columbus, Ohio, U.S.A., Professor of Metallurgy.
- O.M. Lorenz, H., 7 and 8, Idol Lane, London, E.C., Chemical Merchant.
1904. Lorimer, John H., 280, West Walnut Lane, Germantown, Philadelphia, Pa., U.S.A., Textile Machinist and Merceriser.
1905. Loring, Lindsley, Box 160, Boston, Mass., U.S.A., Vice-President (Cochrane Chemical Co.).
- O.M. Lorrain, J. G., Norfolk House, Norfolk Street, Strand, London, W.C., Chartered Patent Agent.
1904. Lossen, Dr. Clemens F., Boulevardul Independentei 8, Ploesti, Roumania, Chemist.
- O.M. Lott, F. E., The Laboratory, Bridge Chambers, Burton-on-Trent, Consulting Brewing Chemist.
- O.M. Louis, D. A., 77, Shirland Gardens, London, W., Metallurgist and Mining Engineer.
1894. Louis, Prof. Henry, Armstrong College, Newcastle-on-Tyne, Professor of Mining.
- O.M. Love, Dr. E. G., 80, East 55th Street, New York City, U.S.A., Analytical Chemist.
1899. Love, Wm., 28, Royal Exchange Square, Glasgow, Managing Director (Broomburn Oil Co., Ltd.).
1895. Lovejoy, Frank W., 22, Seneca Parkway, Rochester, N.Y., U.S.A., Chemical Engineer.
1904. Loveland, Jas. W., 115, Passaic Street, Haekinsack, N.J., U.S.A., Superintendent of Soap Works.
- O.M. Lovibond, J. W., The Pleasaunce, Lake, near Salisbury, Tintometer Manufacturer.

- O.M. Lovibond, T. W., West Jesmond House, Newcastle-on-Tyne, Brewer.
1897. Low, Albert H., P.O. Drawer 1537, Denver, Colo., U.S.A., Metallurgical Chemist.
1900. Low, Prof. Wilson H., Cudahy Packing Co., South Omaha, Neb., U.S.A., Chemist.
1887. Lowe, Clement W., Thorneyholme, Knutsford, Cheshire, Manufacturing Chemist.
1905. Lowe, Houston, The Lowe Bros. Co., Dayton, Ohio, U.S.A., Paint and Varnish Maker.
1906. Lowe, James, c/o Auckland Gas Co., Auckland, New Zealand, Gas Engineer.
- O.M. Lowe, W. F., 18, Hough Green, Chester, Analytical Chemist.
1885. Lowson, Dr. J. G. F., Snitterfield House, Stratford-on-Avon, Paper Maker.
1906. Lowson, Wm., The University, Leeds, Chemical Lecturer.
1895. Lucas, Alf., Survey Department, Giza, Egypt, Analyst.
1892. Lucas, Bernard R., Winnington Park, Northwich, Alkali Works Manager.
- O.M. Lucas, R., Alwinenstrasse 11, Wiesbaden, Germany, Technical Chemist.
1900. Lummus, Walter E., 62, Newhall Street, Lynn, Mass., U.S.A., Manager (Commonwealth Manufacturing Co.).
1903. Lumsden, Alex. A., Forth Chemical Works, Bo'ness, N.B., Technical Chemist.
1888. Lund, Jas., 142, Hawthorne Street, Malden, Mass., U.S.A., Ammonia Works Manager.
1888. Lundholm, Carl O., Nobel's Explosives Co., Ltd., Ardeer Factory, Stevenston, Ayrshire, Manager.
1898. Lundteigen, Andreas, Union City, Mich., U.S.A., Chemist.
- O.M. Lange, Prof. Dr. G., Rämistrasse 56, Zürich, V., Switzerland, Professor of Chemistry.
1894. Lungwitz, Theo., c/o Chas. Pfizer and Co., 81, Maiden Lane, New York City, U.S.A., Chemist.
1885. Lupton, Sydney, 102, Park Street, Grosvenor Square, London, W.
1890. Luthy, Edmund O., 2419, Ohio Avenue, Cincinnati, Ohio, U.S.A., Distiller.
1884. Lüthy, Otto, P.O. Box 63, Maywood, N.J., U.S.A., Analytical Chemist.
1895. Luxmoore, Dr. Chas. M., Central Technical Schools for Cornwall, Truro, Lecturer on Chemistry.
1899. Luxton, Thos., 116, North Boulevard, Hull, Teacher of Chemistry.
1903. Lye, Ernest B., Legrave Hall, near Luton, Beds., Straw Plait Dyer and Bleacher.
1885. Lye, W. T., Legrave Hall, near Luton, Beds., Straw Dyer.
1884. Lyle, James, Ardesco, Plaistow Wharf, Victoria Docks, E., Sugar Refiner.
1885. Lyle, Jno., 21, Mincing Lane, London, E.C., Sugar Refiner.
1902. Lyle, Robert F., Berry Yards Sugar Refinery, Greenock, N.B., Analytical Chemist.
1896. Lynn, Arthur H., 71, College Road, Bromley, Kent, Chemical Works Manager.
1906. Lynch, W. D., 10, Pinckney Street, Boston, Mass., U.S.A., Analytical Chemist.
1899. Lynn, R. Rankine, 7, Highburgh Terrace, Dowanhill, Glasgow, Chemical Engineer.
1902. Lyon, Edwd. H., 520, West 27th Street, New York City, U.S.A., Manufacturing Chemist.
- O.M. Lyon, J. G., The Aire Tar Works, Knottingley, Yorks., Tar Distiller.
1906. Lyons, Robert H., Emporium, Pa., U.S.A., Chemist.
- O.M. Lytle, A. M., North of Ireland Chemical Co., Ltd., 34, Victoria Street, Belfast, Ireland, Chemical Manufacturer.
1891. Macadam, Herbert E., Dalkeith, Glengall Road, Woodford Green, Essex, Manure Works Manager.
1894. Macadam, Stevenson, 55, York Place, Edinburgh, Analytical Chemist.
1891. Macallan, J., 3, Rutland Terrace, Clontarf, Dublin, Analytical Chemist.
1894. McAlley, Robt., Bankside, Falkirk, N.B., Paint Works Manager.
1892. Macara, Thos., jun., 30, Oakfield Road, Stroud Green, N., Chemist.
1889. McArthur, Jno., 262, Trinity Road, Wandsworth Common, S.W., Chemist.
1887. McArthur, J. B., Price's Patent Candle Co., Limited, Bromborough Pool, near Birkenhead, Chemist.
- O.M. McArthur, J. S., 74, York Street, Glasgow, Consulting Chemist and Metallurgist.
1901. MacArthur, Jno. S., 15, St. John's Road, Pollokshields, Glasgow, Paint and Varnish Manufacturer.
1892. McArthur, Thos., Tower Building, Water Street, Liverpool, Drysalter and Dyewood Extractor.
1905. McCallum, A. L., Queen Building, Halifax, N.S., Canada, Analytical and Consulting Chemist.
1898. MacCallum, D. A., 389, Central Chambers, 93, Hope Street, Glasgow, Chemist.
- O.M. McCallum, J. M., Southdeane, Paisley, N.B., Soap Manufacturer.
1894. McCann, Owen, 19, Oriel Street, Vauxhall Road, Liverpool, Printing Ink Manufacturer.
1908. McCarter, Fred. W., 17, Lewis Wharf, Boston, Mass., U.S.A., General Manager.
1909. McCarthy, Harold H., 20, Forbes Street, Bombay, India, Chemist and Druggist.
1905. McCaw, Major W. D., Library, Surgeon General's Office, Washington, D.C., U.S.A., Officer, Medical Department, U.S. Army.
1905. McCleary, Wm., 61, Station Road, Pendlebury, near Manchester, Finisher.
1907. McCombie, Chas., 8, Hartley Road, Leytonstone, N.E., Chemist.
1907. McConnan, Dr. Jas., Chemical Laboratory, Frigorifico, Campana F.C.R., Argentina, Chemist (River-Plate Fresh Meat Co.).
1903. McCourt, Cyril D., 13, Malwood Road, Balham Hill S.W., Research Chemist (Morgan Crucible Co.).
- O.M. McCowan, W., Essex Wharf, Narrow Street, Limehouse, E.
1897. McCrae, Dr. John, Government Laboratories, P.O. Box 1080, Johannesburg, Transvaal, Government Analyst.
1898. McCreath, Wm. D., c/o Quantock Vale Cider Works, North Petherton, Bridgewater, Cider Manufacturer.
1900. McCulloch, John, Glencoe, Lostock Gralam, Cheshire, Chemical Engineer.
1903. McCully, R. E. J., 65, Pelham Road, Gravesend, Kent, Analytical Chemist.
1909. McCune, W. H., American Sheet and Tin Plate Co., Vandergrift, Pa., U.S.A., Chief Chemist.
- O.M. McDaniel, J. J., Woodlands, Bandon, Ireland, Distiller.
- O.M. Macdonald, A., 72, Great Clyde Street, Glasgow.
1907. MacDonald, G. Mac., c/o Union Metallic Co., Bridgeport, Conn., U.S.A., Mechanical Engineer.
1897. MacDonald, G. W., Geddes House, Burch Road, Gravesend, Kent, Explosives Chemist.
- O.M. Macdonald, J. W., Cleveland, The Glebe, Blackheath, S.E., Analytical Chemist.
1902. Macdonald, Peter, jun., c/o Mazapil Copper Co., Ltd., Concepcion del Oro (Apartado No. 5), Saltillo, Zacatecas, Mexico, Analytical Chemist.
1899. MacDonald, S. Fremont, c/o Ashtabula Hide and Leather Co., Ashtabula, Ohio, U.S.A., Tanner.
- O.M. McDonald, T. McG., Wallabo Estate, St. Vincent, West Indies, Sugar Chemist.
1906. Macdougald, Geo. D., City Laboratory, 13, Shore Terrace, Dundee, Analyst.
1895. McDougall, Isaac, jun., 68, Port Street, Manchester, Chemical Manufacturer.
1890. McDougall, J. T., Dunolly, Morden Road, Blackheath, S.E., Manufacturing Chemist.

M

1908. Maas, Milton A., 100, William Street, New York City, U.S.A., Manufacturing Chemist.
1887. Mabery, Prof. Chas. F., Case School of Applied Science, Cleveland, Ohio, U.S.A., Professor of Chemistry.

1907. McDougall, R. K., Glenar buck, Bowling, Scotland, Analytical Chemist.
1906. McDowall, Wm., Oficina Anita, Pampa Central, Antofagasta, Chile, South America, Analytical Chemist.
1906. McDowell, Alex. H., 373, West 123rd Street, New York City, U.S.A., Chemist.
1889. MacEwan, Peter, 64, Southwood Lane, Highgate, N., Editor of "Chemist and Druggist."
1891. McEwen, Atholl F., 40, Handen Road, Lee, S.E., Analytical Chemist and Assayer.
1901. McEwen, Duncan C., Astor House Hotel, Seoul, Korea, Metallurgical Chemist.
1902. McFarland, Alan R., c/o Solvay Process Co., Syracuse, N.Y., U.S.A., Alkali Works Manager.
- O.M. Macfarlane, R. F., Tharsis Copper Works, East Moors, Cardif, Works Manager.
1901. McFarlane, Walter, Sunnyside, Thornliebank, Renfrewshire, Printworks Manager.
1890. McFarlane, W. W., East 20th Street, Chester, Pa., U.S.A., Dyeworks Manager.
1893. McGhie, T. Burns, c/o Quirk, Barton and Co., Normandy Wharf, Rotherhithe, S.E., Analytical Chemist and Assayer.
1904. McGill, A., 317, Queen Street, Ottawa, Canada, Analytical Chemist.
1899. MacGillivray, Wm. A., c/o Swansea Safety Fuse Co., Pipe House Wharf, Swansea, Analytical Chemist.
1887. McGlashan, John, Cawnpore Sugar Works, Cawnpore, India, Technical Chemist.
1902. McGovney, Chas. S., 722, East 19th Street, Indianapolis, Ind., U.S.A., Chemist.
1884. McGowan, John, Ash House, Talke, near Stoke-upon-Trent, Colliery Manager.
1906. McGregor, Russell, 20, Havelock Square, Sheffield, Analytical Chemist.
1905. McGrigor, G. D., Perran Mine, Marazion, Cornwall, Mine Owner.
1896. McIlhiney, Dr. Parker C., 7, East 42nd Street, New York City, U.S.A., Chemist.
1894. McIlwaine, Alf. W., Stoneferry, Hull, Oil Manufacturer.
- O.M. MacIndoe, G. D., Ness Street, Invercargill, New Zealand, Public Analyst and Consulting Chemist.
1903. Macintire, Benj. Conid, U.S. Geological Survey, 40th and Butler Streets, Pittsburg, Pa., U.S.A., Chemist.
1888. MacKean, Wm., 208, Bedford Hill, Balham, S.W., Technical Chemist.
- O.M. McKechnie, D., Heath House, Runcom, Copper Extractor.
- O.M. McKechnie, D. M., The Grange, Halewood, near Liverpool, Copper Extractor.
1904. McKechnie, R. D., Minas de Rio Tinto, Provincia de Huelva, Spain, Chemist.
1887. McKellar, W. G., c/o United Alkali Co., Ltd., St. Rollox Works, Glasgow, Technical Chemist.
1895. McKenna, Dr. Chas. F., 50, Church Street, New York City, U.S.A., Chemist.
1899. McKenzie, Alex. H., 17, North Street, North Adams, Mass., U.S.A., Colour Mixer.
1909. Mackenzie, Kenneth G., The New York Testing Laboratory, Maurer, N.J., U.S.A., Chemist.
1893. McKerrrow, C. A., Wingfield, Wilmslow, Cheshire, Consulting Chemist.
1905. McKerrrow, W. J., 12, Chadwick Road, Leytonstone, N.E., Analytical Chemist.
1893. McKesson, John, 91, Fulton Street, New York City, U.S.A., Manufacturing Chemist.
1891. Mackey, W. McD., Victoria Chambers, Leeds, Analytical Chemist.
1900. McKillop, George F., Broxburn Oil Works, Broxburn, N.B., Works Chemist.
1890. McKillop, Jno., 93, Brook Green, London, W., Metallurgist.
1902. McKim, Wm., 37, Fairview Street, Yonkers, N.Y., U.S.A., Colour Maker.
1908. McLaren, Alex., 11, Willowdale Road, Fazakerley, Liverpool, Analytical Chemist.
1908. McLaren, Alex. W., 3, Hayfield Terrace, Langside, Glasgow, Analytical Chemist.
1898. McLaurin, Robt., 414, Sauchiehall Street, Glasgow Chemist.
1905. McLellan, Basil G., c/o Rowntree & Co., Ltd., The Cocoa Works, York, Analytical Chemist.
1908. Macleod, Alex., Mount Pleasant, Old Kilpatrick, N.B., Analytical Chemist.
1892. McLeod, Jas., Gas Works, Greenock, N.B., Manager.
1903. MacMahon, F. W., 31, Marler Road, Forest Hill, S.E., Chemist (Oxychlorides, Ltd.).
1896. McMaster, Daniel, Bemis, Albert Road, Falkirk, N.B., Paper Mill Manager.
1894. Macmillan, Arch., c/o Dr. Crombie, Main Street, Mechanicville, N.Y., U.S.A.
1907. McMillen, Russell H., c/o American Vanadium Co., Bridgeville, Pa., U.S.A., Chemist.
1903. McMullan, Charles, 4, William Street Chambers, Belfast, Ireland, Chemist.
1904. McMullen, Alan, 108, James Street, Dublin, Ireland, Brewer.
1889. McMurtrie, J. M., 320, Maxwell Road, Pollokshields, Glasgow, Brass Founder.
1900. McMurtrie, Dr. Wm. T., 480, Park Avenue, New York City, U.S.A., Chemist.
1895. McMurtry, G. C., Mount Street, Nelson, New Zealand; and (Subscriptions) c/o C. H. Izod, 84, Queen Victoria Street, London, E.C., Manager.
- O.M. Macnab, W., 10, Cromwell Crescent, London, S.W., Analytical Chemist.
1907. McNaughton, Wm. G., Port Edwards, Wis., U.S.A., Chemist.
1907. Macpherson, Robert, 24, King William Street, London, E.C., Managing Director (Sapon, Ltd.).
1908. McQueen, James, jun., Clyde House, Uddingston, N.B., Analytical Chemist.
1894. McVitie, Robt., Biscuit Works, Willesden, N.W., Biscuit Manufacturer.
1901. Maertens, Emile, P.O. Box 1002, Providence, R.I., U.S.A., Engineer.
1895. Magnus, Isidor, 52, Leadenhall Street, London, E.C., Chemical Merchant.
1901. Magruder, Egbert W., Department of Agriculture, Richmond, Va., U.S.A., Chemist.
1906. Maguire, Peter, 5, King's Bench Walk, Temple, London, E.C., Chemist and Colourist.
1885. Mahon, R. W., N.Y. Central and Hudson River Railroad, West Albany, N.Y., U.S.A., Chemist.
1898. Main, Wm., Piermont, N.Y., U.S.A., Chemist.
1904. Mair, William, 7, Comiston Road, Edinburgh, Chemist.
1905. Major, Ernest, Day Street, Drummoyne, Sydney, N.S.W., Australia, Paint Works Manager.
- O.M. Major, J. Lewis, Welton Garth, Brough, East Yorks., Tar Distiller and Chemical Manufacturer.
1886. Mallinckrodt, Edw., Mallinckrodt Chemical Works, St. Louis, Mo., U.S.A., Manufacturing Chemist.
1897. Mallory, J. Halsey, Drawer 69, Columbia, S.C., U.S.A., Assistant Chemist (The American Cotton Oil Co.).
1908. Manahan, Paul R., 14, Newbury Street, Boston, Mass., U.S.A., Salesman.
1908. Mander, C. Arthur, The Mount, Wolverhampton, Varnish Manufacturer.
1896. Mann, E. A., Government Laboratory, Perth, Western Australia, Government Analyst.
1893. Mann, Harold H., Agricultural College, Poona, Bombay, India, Research Chemist.
1899. Mann, Jas. S., 19, Stopford Road, Upton Manor, Essex, Analyst.
1891. Mann, John C., Ash Villa, Thynne Street, West Bromwich, Staffs., Chemist.
1903. Mannhardt, Hans, 1653, Briar Place, Chicago, Ill., U.S.A., Chemical Engineer.
- O.M. Mannington, H. T., Marshlea, Beaconsfield Road, Farnworth, Widnes.
1892. Mansbridge, Wm., 4, Norwich Road, Wavertree, Liverpool, Chemist.
1909. Mantius, Otto, 618, Fidelity Mutual Building, Philadelphia, Pa., U.S.A., Engineer.
1904. Marekworth, O. S., Ohio Testing Laboratory, 25 and 26, Board of Trade, Columbus, Ohio, U.S.A., Analytical Chemist.

1883. Markel, Dr. K., Tower House, Bewsey, Warrington, Technical Chemist.
1905. Marland, Percy, c/o Brotherton and Co., Ltd., Ammonia Works, Wakefield, Yorks., Chemist.
1905. Marlatt, Wilbur T., Oakville, Ont., Canada, Leather Manufacturer.
1902. Marriott, F. Grant, 14, Selby Street, Toronto, Canada, Chemical Student.
1904. Marris, H. C., The Russian Steam Oil Mills Co., 32, Kourlandski Street, St. Petersburg, Russia, Analytical Chemist.
1901. Marsden, Dr. Fred., St. James' Terrace, Woodside, Horsforth, Leeds, Chemist.
1906. Marsden, Oliver, Manor Road Mill, Victoria Road, Leeds, Cashier.
- O.M. Marsh, J. T., Ammonia Soda Works, Fleetwood, Lancashire, Chemist.
1883. Marsh, W., Union Alkali Co., Soho Works, Ancoats, Manchester, Chemical Manufacturer.
1895. Marshall, Arthur, Naini Tal, India, Chief Chemical Examiner.
1895. Marshall, Francis G., 91, Bewick Road, Gateshead, Technical Chemist.
1891. Marshall, Dr. Hugh, 12, Lonsdale Terrace, Edinburgh, Professor of Chemistry.
1908. Marshall, John, Cudbear Street, Hunslet, Leeds, Dyeware Manufacturer.
1901. Marshall, Jos. W., Science Lecturer.
1896. Marshall, Percy S., Union Laboratory, Half Moon Street, Huddersfield, Assistant Chemist.
1883. Marshall, Wm., Carlsbrook, Queen's Road, Cheadle Hulme, Cheshire, Dyer.
1884. Marshall, Wm., Barkley, Teddington, Middlesex, Analytical Chemist.
1904. Marston, John P., 247, Atlantic Avenue, Boston, Mass., U.S.A., Merchant.
1894. Martin, Alex. M., Hillview, Twechar by Glasgow, Analytical Chemist.
1895. Martin, Chas. H., 40, Bolton Road, Pendleton, Salford, Oil and Soap Works Manager.
- O.M. Martin, N. H., Ravenswood, Low Fell, Gateshead-on-Tyne, Manufacturing Chemist.
1899. Martin, Wm. E., c/o Kynoch Ltd., Arklow, Co. Wicklow, Ireland, Chemist.
1887. Martineau, Sydney, Streatham Grove, Norwood, S.E., Sugar Chemist.
1907. Martius, Dr. C. A. von, Voss Strasse 12, Berlin, Germany, Chemist.
1894. Martyn, T. Graham, II, Stratton Terrace, Truro, Cornwall, Metallurgist.
1905. Marx, Dr. Emil, Ruckerstrasse 17, Schweinfurt a/Main, Bavaria, Germany, Research Chemist.
1905. Marx, Dr. Max, 81, Shanley Avenue, Newark, N.J., U.S.A., Manufacturing Chemist.
1908. Mason, Douglas H. C., 477, Sherbourne Street, Toronto, Canada, Manufacturer.
1904. Mason, Dr. Edward D., 22, George Road, Edgbaston, Birmingham, Scientific Apparatus Dealer.
1906. Mason, Frederic S., 90, Beekman Street, New York City, U.S.A., Manufacturing Chemist.
1904. Mason, Glen F., c/o H. J. Heinz Co., Pittsburg, Pa., U.S.A., Chemist.
1887. Mason, J. Francis, Eynsham Hall, Witney, Oxon.
1906. Mason, M. Edgar, 93, Orleans Street, Chicago, Ill., U.S.A., Chemist.
1906. Massa, Corradino, Castelnello Parmense, Parma, Italy, Sulphuric Acid and Fertiliser Manufacturer.
- O.M. Masson, Prof. D. Orme, University of Melbourne, Victoria, Australia, Professor of Chemistry.
1908. Masson, R. Duncan, c/o Messrs. R. Silcock and Sons, Stanley Hall, Union Street, Liverpool, Analytical Chemist.
1904. Masson, Victor E., Pleasant Valley Wine Co., Rheims, Steuben Co., N.Y., U.S.A., Chemist.
1902. Masujima, Prof. Bunjiro, c/o K. Takebe, 25, Gazenbocho, Azabuku, Tokyo, Japan, Prof. of Applied Chemistry.
1902. Masury, Fred L. M., Lock Box 144, Sharon, Pa., U.S.A., Explosives Manufacturer.
- O.M. Mather, J., Blaydon Chemical Works, Blaydon-on-Tyne, Manager.
1904. Mather, J. Cecil, The Slide, Runcorn, Cheshire, Works Chemist.
1900. Mather, Wm., Westlea, Queen Street, Alexandria, Dumbartonshire, Chemist.
1907. Matheson, A. Greville E., c/o Matheson & Grant, 13, Walbrook, London, E.C., Engineer.
1890. Matheson, W. J., c/o Cassella Colour Co., 182, Front Street, New York City, U.S.A., Chemical Merchant.
1901. Mathew, W. E. B. de Vere, Dinham, Hillside Gardens, Wallington, Surrey, Analytical Chemist.
1900. Mathews, Dr. Jno. A., c/o Halcombe Steel Co., Syracuse, N.Y., U.S.A., Works Manager and General Superintendent.
1898. Mathewson, E. P., Anaconda, Mont., U.S.A., Metallurgist.
1888. Mátyos, Louis J., 101, North 19th Street, East Orange, N.J., U.S.A., Chemist.
1896. Matsui, G., c/o Japan Sugar Refinery Co., Onagigawa, Tokio, Japan, Chemical Engineer.
- O.M. Matthews, Chas. G., 31, Stapenhill Road, Burton-on-Trent, Brewing Chemist.
1907. Matthews, Dr. F. E., 6, Hillcroft Crescent, Ealing, W., Technical Chemist.
1899. Matthews, Dr. J. Merritt, 3, Bow Street, Taunton, Mass., U.S.A., Professor of Chemistry and Dyeing.
1889. Mawdsley, W. H., c/o Gold Mining Co., Ltd., Mount Morgan, Queensland, Chemist.
1906. Mawson, Fred. E., 88, Broad Street, Boston, Mass., U.S.A., Dyestuff Merchant.
1903. Maxim, Hudson, 698, St. Mark's Avenue, Brooklyn, N.Y., U.S.A., Chemist and Mechanical Engineer.
1894. Maxwell, Jno., Solway Chemical Works, Silloth, and (communications) English Street, Carlisle, Cumberland, Chemical Manure Manufacturer.
1903. Maxwell, Orin P., Piedmont, Mineral Co., West Va., U.S.A., Chemist.
1897. May, George H., c/o Fabrikoid Co., Newburgh, N.Y., U.S.A., Assistant Chemist.
1884. Mayenfeld, Dr. E. von Salis. *See* Salis-Mayenfeld, Dr. E. von.
1903. Mayer, Andrew, jun., 129, York Street, Brooklyn, N.Y., U.S.A., Chemist.
1908. Mayer, Frederick J., c/o Didier-March and Co., 50, Church Street, New York City, U.S.A., General Manager.
1896. Mayfield, A. S., Thirlmere, Newland, Hull, Analyst.
1892. Mayfield, H. E., Normanhurst, Mundy Street, Heanor, near Nottingham, Dyer.
1885. Mayhew, E. W. A., High Street, Freemantle, Western Australia, Manufacturing Chemist.
1907. Maynard, Geo. W., 20, Nassau Street, New York City, U.S.A., Mining Engineer.
1900. Maywald, F. J., 1028, 72nd Street, Brooklyn, N.Y., U.S.A., Technical Chemist.
1907. Meade, Geo. P., National Sugar Refinery, Yonkers, N.Y., U.S.A., Chemist.
1902. Meade, Richd. K., Nazareth, Pa., U.S.A., Chemist.
1904. Meads, Charles J., 19, Park Place West, Sunderland, Inland Revenue Officer.
1898. Meeds, Alonzo D., 2424, Harriet Avenue, Minneapolis, Minn., U.S.A., Analytical Chemist.
1896. Meggitt, Loxley, Wheatstef Works, Alexandrina, Sydney, N.S.W., Australia, Analytical Chemist.
1901. Meier, Dr. Franz, c/o Society of Chemical Industry in Basle, Basle, Switzerland, Chemist.
1888. Meikle, Jno., 8, Melrose Street, Great Western Road, Glasgow, Journalist.
1902. Melcher, Arthur C., 58, Bowen Street, Newton Centre, Mass., U.S.A., Research Chemist.
- O.M. Meldola, Prof. R., F.R.S., 6, Brunswick Square, London, W.C., Professor of Chemistry.
1901. Meldrum, Dr. And. N., Chemical Department, The University, Manchester, Lecturer on Chemistry.
- O.M. Mellon, W. W., Woodlands, Blackrook, Co. Dublin, Ireland, Manufacturing Chemist.
- O.M. Mellor, S., Magnesium Metal Co., Patricroft, Manchester, Metal Refiner.

1884. Melville, D., 2, Melville Avenue, Delray, Detroit, Mich., U.S.A., Chemical Works Manager.
1893. Mensching, Dr. C., Mersey Chemical Works, Bromborough, Cheshire, Chemist.
- O.M. Menzies, R. C., Inveresk Mills, Musselburgh, N.B., Paper Maker.
1892. Mercer, C. A., 31, Camomile Street, London, E.C., Chemical Apparatus Maker.
1886. Mercer, J. B., 4, Tabley Road, Knutsford, Cheshire, Chemist.
1890. Merck, Dr. E., Darmstadt, Germany, Manufacturing Chemist.
1905. Merck, George, Merck and Co., University Place, New York City, U.S.A., Manufacturing Chemist.
1899. Merrill, Frank H., 2424, Ocean View Avenue, Los Angeles, Cal., U.S.A., Factory Superintendent.
1906. Merrills, Fred. J., 25, Figtree Lane, Sheffield, Analytical Chemist.
1909. Merriman, H. J., 244, Victoria Park Road, South Hackney, N.E., Research Chemist.
1905. Merrin, A. C., 44, Bishopgate Street Without, London, E.C., Assistant Editor and Analyst.
1904. Merry, Jno. B., 112, Greenfield Road, Harborne, Birmingham, Metallurgical Chemist.
1903. Mersan, Ferdinand de, Fairfield, Chestnut Avenue, Boston Spa, Yorks., Chemist.
1905. Merz, Eugene, P.O. Box 216, Newark, N.J., U.S.A., General Superintendent, Heller and Merz Co.
1905. Merzbacher, Aaron, Hotel Monaca, Monaca, Pa., U.S.A., Chemist.
1897. Meslans, Prof. M., 59, Quai de la Baronnie, Ablon (Seine et Oise), France, Professor of Chemistry.
- O.M. Messel, Dr. R., 147, Victoria Street, London, S.W., Chemical Manufacturer.
1899. Metcalf, Howard F., Farr Alpaca Co., Holyoke, Mass., U.S.A.
1886. Metcalf, Jno., Moorfield Chemical Works, Altham, near Acreington, Tar Distiller.
1908. Metcalfe, Ernest D., 3, Gracechurch Street, London, E.C., Secretary.
1905. Methley, Bernard, 1, Es-la-forde, Doncaster Road, Rotherham, Yorks., Engineering Chemist.
1898. Metz, Herman A., P.O. Box 753, New York City, U.S.A., Chemical Merchant.
1905. Metzis, Josef, Angliacia Petroleum Co., Drohobycz, Galicia, Austria, Manager of Refinery.
1900. Mewborne, Robt. G., c/o Kentucky Tobacco Products Co., Louisville, Ky., U.S.A., Chemist.
1907. Meyer, Dr. Erwin, c/o Morgan and Wright, Detroit, Mich., U.S.A., Chemist.
1898. Meyer, Dr. Franz, c/o R. Wedekind und Co., Uerdingen a/Rhein, Germany, Metallurgical and Chemical Engineer.
1900. Meyer, Karl, Sortedams Dossering 95A, Copenhagen, O., Denmark, Technical Chemist.
1904. Meyer, Prof. Dr. Richard, Technische Hochschule, Braunschweig, Germany, Professor of Chemistry.
1902. Meyrick, L. J., 137, City Road, Birmingham, Assistant Analyst.
1907. Micklethwait, Miss Frances M. G., Penhein, Chestow, Mon.; and (Journals) Royal College of Science, London, S.W., Chemist.
1904. Mighill, Dr. Thos. A., 15, Exchange Street, Boston, Mass., U.S.A., Chemist.
1896. Miles, G. Wellington, 29, Central Street, Boston, Mass., U.S.A., Analytical Chemist.
1889. Milestone, W. C., 7, Heathfield Road, Wandsworth Common, S.W., Chemical Works Manager.
1899. Millar, Jas. H., P.O. Box 120, Durban, Natal, Manufacturing and Analytical Chemist.
1897. Millard, Edgar J., 40-42, Charlotte Street, London, E.C., Chemist and Manager.
1903. Millen, J. Dunlop, Mount Bischoff Mine, Waratah, Tasmania, Assistant General Manager.
1883. Miller, Dr. A. K., Kilvert's Buildings, Withy Grove, Manchester, Analytical Chemist.
- O.M. Miller, E. V., Sugar Works, Chelsea, Auckland, New Zealand, Sugar Works Chemist.
1889. Miller, Geo., Clydesdale, Groes Road, Cressington, Liverpool, Technical Chemist.
1893. Miller, Dr. Harry E., 305, Palm Avenue, Oakland, Cal., U.S.A., Chemist.
1883. Miller, Dr. H. von, Beatrixgasse 32, Wien, Austria, Chemical Manufacturer.
1904. Miller, Jas., Pharmacist.
1894. Miller, Dr. John A., 44-45, Lewis Block, Buffalo, N.Y., U.S.A., Consulting Chemist, State Analyst.
1908. Miller, John B., 98, Wellesley Street, Toronto, Canada, Lumber and Iron Manufacturer.
1894. Miller, J. Carlile, 188, St. Vincent Street, Glasgow, Manufacturing Chemist.
1888. Miller, J. Hopkins, 5, Catherine Street, Parliamentary Road, Glasgow, Dyeworks Chemist.
1889. Miller, Jno. Poynter, Sandilands Chemical Works, Aberdeen, Technical Chemist.
1907. Miller, R. H., c/o The Flavell Co., Box 924, Asbury Park, N.J., U.S.A., Chemical Manufacturer.
1901. Miller, Stuart B., c/o E. I. du Pont de Nemours Powder Co., Marquette, Mich., U.S.A., Chemical Engineer.
1904. Miller, William Exley, c/o The Arizona Copper Co., Ltd., 29, St. Andrew Square, Edinburgh, Secretary.
1901. Miller, Dr. W. Lash, 50, St. Alban Street, Toronto, Canada, Associate Professor of Physical Chemistry.
1884. Miller, W. M., Caledonia Estate, Prov. Wellesley, Penang, S.S., Sugar Chemist.
1902. Milligan, R. E., New York Continental Jewell Filtration Co., 15, Broad Street, New York City, U.S.A., Chemical Engineer.
1904. Millroy, Alfred T., c/o Lyman, Sons & Co., St. Paul Street, Montreal, Canada, Laboratory Furnisher.
- O.M. Mills, Prof. E. J., F.R.S., 64, Twyford Avenue, West Acton, W., Emeritus Professor of Technical Chemistry and Consulting Chemist.
1901. Mills, Dr. J. E., University of North Carolina, Chapel Hill, N.C., U.S.A., Associate Professor of Chemistry.
1905. Mills, Wm. Henry, 45, Wall Street, New York City, U.S.A., Merchant.
1906. Mills, Wm. Hobson, Northern Polytechnic Institute, Holloway, London, N., Lecturer in Chemistry.
1905. Milne, Thomas, c/o The Gas Light and Coke Co., Ltd., 4, Fenchurch Avenue, London, E.C., Chemical Products Salesman.
1903. Milnes, Cresswell, Arlesey, near Hitchin, Herts., Cement Works Manager.
1887. Milnes, Edmund, Seedfield, Bury, Lancashire, Dyeing Extract Maker.
1902. Milnes, Ernest E., c/o Joseph Smithson, Ltd., India Buildings, Halifax, Yorks., Chemist.
1895. Miner, Harlan S., c/o Welshbach Light Co., Gloucester City, N.J., U.S.A., Technical Chemist.
1889. Miniati, T. K., Penketh, near Warrington, Chemist.
1907. Minns, J. E., 32, North Street, Taunton, Somerset, Analytical Chemist.
1895. Mitchell, Chas. A., c/o Beaufoy and Co., South Lambeth Road, S.W., Analyst.
1901. Mitchell, Frank H., c/o Dill and Collins, Richmond and Tioga Streets, Philadelphia, Pa., U.S.A., Tutor in Chemistry.
1898. Mitchell, G. D. H., c/o S. S. White Dental Manufacturing Co., Prince's Bay, Staten Island, N.Y., U.S.A., Chemist.
1906. Mitchell, Oswald H., c/o Basil Turner, Woolwich, Sydney, N.S.W., Australia, Assayer.
1904. Mitsugi, R., Münchenerstrasse 22, Dresden, Germany, Chemist.
- O.M. Mitting, E. Kennard, 38, Harold Road, Norwood, S.E., Technical Chemist.
1908. Miyake, Hanzaburo, Girls' School, Kami-Nagarekawa, Hiroshima, Japan, School Teacher.
1909. Mock, Hugo, 220, Broadway, New York City, U.S.A., Lawyer.
1905. Modi, Dr. E. M., Opposite Grant Road Station, Sleater Road, Bombay, India, Manufacturing and Analytical Chemist.
1906. Moe, Eldor H., Box 266, Salt Lake City, Utah, U.S.A., Chemist.
- O.M. Mohr, Dr. B., 69A, Parliament Hill, Hampstead, N.W., Consulting Chemist and Metallurgist.
1894. Mole, Herbert B., The Croft, Shepton Mallet, Somerset, Brewer.

1902. Molesworth, F. H., Jersey Road, Aitarmon, N.S.W., Australia, Analytical Chemist.
1906. Moller, Emil A., 18, Teresa Place, Stapleton, Staten Is., N.Y., U.S.A., Manager (Sanitas Co.).
1901. Mond, Dr. Albert L., 416-418, Birkbeck Bank Chambers, Holborn, London, W.C., Chemical Engineer.
1899. Mond, Emile S., 22, Hyde Park Square, London, W., Technical Chemist.
- O.M. Mond, Dr. L., F.R.S., 20, Avenue Road, Regent's Park, N.W.; and 64, Via Sistina, Rome, Alkali Manufacturer.
1891. Mond, Robt. L., Winnington Hall, Northwich, Chemist.
1906. Monier-Williams, G. W., The Lammas, Esher, Surrey.
1908. Monk, Chas. W., 102, Bloomfield Road, Plumstead, Kent, Chemist.
1909. Monro, Irwin W., c/o W. E. Smith and Co., Ltd., Madras, India, Manufacturing Chemist.
1890. Moodie, Wm. E., Alexandria Works, Alexandria, N.B., Analytical Chemist.
1901. Moody, Chas. J., Oroya Brown Hill Mine, Kalgoorlie, West Australia, Analyst and Assayer.
1905. Moody, Dr. Gerald T., Lorne House, North Dulwich, S.E., Lecturer on Chemistry.
1898. Moody, Dr. Herbert R., College of the City of New York, and (Journals) 23, Hamilton Terrace, New York City, U.S.A., Science Instructor.
1903. Mooney, F. M., 118, Pembroke Road, Dublin, Chemical Manure Manufacturer.
1903. Mooney, Geo. A., 310, St. Paul Street, Montreal, Canada, Chemical Merchant.
1902. Mooney, Luke, 36, West 52nd Street, Bayonne, N.J., U.S.A.
1887. Moore, Chas. C., 33, Clarendon Road, Garston, Liverpool, Chemist.
1901. Moore, Dr. Chas. W., Wellcome Chemical Research Laboratories, 6, King Street, Snow Hill, London, E.C., Chemist.
1907. Moore, Ernest P., Burlington, Ont., Canada, Chemist.
1902. Moore, Fred., Victoria Chemical Co., Ltd., Victoria, B.C., Canada, Manufacturing Chemist.
1906. Moore, F. H., 39, Lime Street, London, E.C., Analytical Chemist.
1892. Moore, Dr. Geo. D., 201, Salisbury Street, Worcester, Mass., U.S.A., Professor of Chemistry.
1905. Moore, Leslie R., 173, Oakleigh Road, Newton, Mass., U.S.A., Chemist.
1899. Moore, Quintin, jun., c/o Wm. Beardmore & Co., Ltd., Parkhead Forge, Glasgow, Works Manager.
1885. Moore, R. T., 142, St. Vincent Street, Glasgow, Mining Engineer.
1899. Moore, Dr. Russell W., 25, East 30th Street, New York City, U.S.A., Chemist (U.S. Appraiser's Office).
1890. Moore, Thos., Laboratoire du Service Local, Noumea, New Caledonia, Analytical Chemist.
1905. Moorwood, F. Colin, c/o W. H. Dyson, The Amalgams Co., Ltd., Attercliffe Road, Sheffield, Steel Manufacturer.
1903. Moran, Geo. A., 6, Reservoir Terrace, Lawrence, Mass., U.S.A., Chemist.
1890. Mordle, F. Dare, Guilderoy, Matlock Bath, Derbyshire, Starch Manufacturer.
1902. More, Andrew, 61, Quarrendon Street, Fulham, S.W., Analytical Chemist.
1906. Morewood, C. Darcy, Frodingham Ironstone Mines, Scunthorpe, near Doncaster, Analytical Chemist.
1908. Morfev, Harold, Mitchell Main Colliery Co., Ltd., Wombwell, near Barnsley, Manager of By-Products Works.
1901. Morgan, Dr. Gilbert T., Royal College of Science, South Kensington, S.W., Demonstrator of Chemistry.
1905. Morgan, Prof. Jerome J., College of Hawaii, Honolulu, Hawaiian Islands, Teacher.
890. Morgan, J. Jas., Laboratory, Cammell, Laird and Co., Workington, Cumberland, Assayer.
1907. Morgan, Leonard P., United States Mint, Philadelphia, Pa., U.S.A., Electro-Chemist.
1906. Morgan, Thos., "Meirion," Dovedale Road, Mossley Hill, Liverpool, Manufacturing Chemist.
1898. Morgan, T. M., 370, Wood Avenue, Westmount, Quebec, Canada, Cement Works Manager.
- O.M. Moritz, Dr. E. R., 45, Great Tower Street, London, E.C., Brewing Chemist.
1885. Morley, Dr. H. Forster, 5, Lyndhurst Road, Hampstead, N.W., Professor of Chemistry.
1902. Morrell, Dr. R. S., Messrs. Mander Bros., Colour and Varnish Works, Wolverhampton, Chemist.
1884. Morrice, Jas. A., 1, Prince's Terrace, Dowanhill, Glasgow, Starch and Gum Manufacturer.
1908. Morrill, Geo. E., 6, Lemoine Street, Montreal, Canada, Local Manager, Badische Co.
1906. Morris, A. H., 72, Chorley New Road, Bolton, Lanes., Brewer.
1898. Morris, Edgar F., c/o Cornbrook Chemical Co., Ltd., Colour Works, Stockport, Research Chemist.
1897. Morris, Harry, The Hall, Hexthorpe, Doncaster, Chemical Merchant.
1890. Morris, Herbert N., Gorton Brook Chemical Works, Manchester, Technical Chemist.
- O.M. Morris, J. Haydn, 22, Largo das Fontanhas, Lisbon, Portugal, Technical Chemist.
1908. Morris, Wm. J., Glebe Terrace, Frodsham, Cheshire, Chemist.
1902. Morrison, Jos., Wellfield, Farnworth, Widnes, Manager.
1906. Morrow, Jas. M., 49, Townsend Place, Kirkealdy, N.B., Analytical Chemist.
1901. Morse, Willard S., Amer. Smelters Securities Co., 165, Broadway, New York City, U.S.A., Manager.
1909. Morson, Leslie J., Summerfield Works, Ponders End, Middlesex, Manufacturing Chemist.
1904. Morson, Thos. D., 14, Elm Street, Gray's Inn Road, London, W.C., Chemist.
1906. Morson, T. Pierre, 14, Elm Street, Gray's Inn Road, London, W.C., Chemical Manufacturer.
1907. Morton, George A., Haxley Mills, Silver Street, Edmonton, N., Analyst.
1889. Morton, Jas., Dalquhurn Works, Renton, N.E., Dyeworks Manager.
1897. Morton, Jno., North Road, St. Helens, Lancashire, Analytical Chemist.
1902. Mosbaugh, F. R., c/o Anglo-Canadian Leather Co., Huntsville, Ont., Canada, Chemist.
1905. Moseley, F. A. D. H., Box 1657, Johannesburg, Transvaal, Analytical Chemist.
1888. Mosenthal, Henry de, 220, Winchester House, Old Broad Street, E.C., Explosives Company Manager.
1894. Moszczenski, J. B., 216, Stillman Place, Brooklyn, N.Y., U.S.A., Consulting Chemist.
1897. Motion, Jno., c/o The Joseph Dixon Crucible Co., Jersey City, N.J., U.S.A., Assistant Superintendent.
1887. Moul, Frank, Akdersgate Chemical Works, Southall, Technical Chemist.
1901. Moule, Jno. W., c/o The Chillagoe Co., Ltd., Chillagoe, Queensland, Metallurgist.
1884. Moul, J., Underhill, Low Fell, Gateshead-on-Tyne, Secretary.
1898. Moulton, Prof. Chas. W., Vassar College, Poughkeepsie, N.Y., U.S.A., Professor of Chemistry.
1905. Moulton, Rt. Hon. Sir J. Fletcher, F.R.S., 57, Onslow Square, London, S.W., Lord Justice of Appeal.
1892. Mount, Edw., Oaklands, Aughton, near Ormskirk, Assistant Secretary (United Alkali Company).
1905. Mrazsek, F. M., 31, West Cromwell Road, London, S.W., Consulting Chemist.
1904. Muckenfuss, A. M., c/o University of Mississippi, University, Miss., U.S.A., State Chemist.
1907. Mueller, Dr. Carl, The Heyden Chemical Works, Garfield, N.J., U.S.A., Chemist.
1890. Muir, Jas. Stanley, 8, Westminster Gardens, Glasgow, W., Chemist.
1894. Muir-Smith, W., c/o A. B. Fleming and Co., Ltd., Caroline Park, Edinburgh, Oil Works Manager.

- O.M. Müller, Dr. H., F.R.S., 13, Park Square East, Regent's Park, London, N.W., Research Chemist.
1896. Mundy, Lionel, 27, Merton Road, Kensington, W., Importer of Unfermented Wines.
1887. Munroe, Prof. Chas. E., George Washington University, Washington, D.C., U.S.A., Professor of Chemistry and Dean.
1900. Munsell, Dr. Chas. E., c/o Devoe and Reynolds Co., 110, Horatio Street, New York City, U.S.A., Colour Chemist.
1900. Muntion, Fred T., The Oak House, Winsford, Cheshire, A.R.S.M., Analytical Chemist.
1897. Murch, D. Wilshin, 6, Victoria Road, Wednesbury, Staffs, Chemist.
1904. Murdoch, Alexander, 557, Alexandra Parade, Dennistoun, Glasgow, Analytical Chemist.
1886. Murdoch, R. H. M., Nobel Villas, Stevenston, Ayrshire, Explosives Chemist.
1899. Murphy, Albert J., 28, Great George Street, Leeds, Brewer's Chemist.
1906. Murphy, Frederic W., Standard Sugar Refinery, Granite Street, South Boston, Mass., U.S.A., Chemist.
1901. Murray, Benjamin L., c/o Merck and Co., University Place, New York City, U.S.A., Chemist.
1903. Murray, Chas. B., 407, Perry Payne Building, Cleveland, Ohio, U.S.A., Chemist.
1901. Murray, Jas. P., Toronto Carpet Manufacturing Co., Ltd., King Street, and Fraser Avenue, Toronto, Canada, Carpet Manufacturer.
1909. Murray, John C., 313, Confederation Life Building, Toronto, Canada, Editor (Canadian Mining Journal).
1898. Murray, Rd., c/o Brotherton and Co., Ltd., Ammonia Works, Holmes Street, Leeds, Analyst.
1908. Murray, Dr. Thos. J., The University, Birmingham, Lecturer on Chemistry.
1905. Murray, Wm. Wallace, c/o Union Abattoir Co., Baltimore, Md., U.S.A., Chemist.
1905. Murrill, Dr. Paul I., P.O. Box 986, Wilmington, Del., U.S.A., Representative, E.I. du Pont Co.
- O.M. Muspratt, Dr. E. K., Seaforth Hall, near Liverpool, Alkali Manufacturer.
1894. Muspratt, Max, The Grange, Fulwood Park, Liverpool, Technical Chemist.
- O.M. Muspratt, S. K., 14, Northgate, Regent's Park, N.W., Alkali Manufacturer.
1907. Musso, Louis A., Department of Agriculture, 140, George Street North, Sydney, N.S.W., Australia, Assistant Viticulturist.
- O.M. Muter, Dr. Jno., Winchester House, Horley, Surrey, and (Journals) 325, Kennington Road, London, S.E., Chemical Lecturer.
1895. Muirling, I. J. R., 117, Hudson Street, New York City, U.S.A., Dyestuff Importer.
1891. Myers, Dr. Wm. S., 71, Nassau Street, New York City, U.S.A., Director.
1904. Napper, Sidney S., c/o S. Comtauld & Co., Ltd., Foleshill Road, and (Journals) 57, Barras Lane, Coventry, Chemist.
1903. Nash, A. Douglas, 280, State Street, Flushing, N.Y., U.S.A., Glass Manufacturer.
1897. Nash, Leonard M., Westlands, Princess Road, Finsbury Park, N., Works Chemist.
1905. Nash, W. A., Corn Exchange Bank, New York City, U.S.A., President, Corn Exchange Bank.
1908. Nasmith, M. E., 66, Jarvis Street, Toronto, Canada, Baker.
1900. Nathan, Lt.-Col. Sir Frederic L., R.A., Royal Gunpowder Factory, Waltham Abbey, Essex, Superintendent.
1907. Nauckhoff, Sigurd, c/o Nitroglycerin Aktiebolaget, Vinterviken, Stockholm, Sweden, Chemical Engineer.
1892. Naylor, Wm., 3, Garstang Road, Fulwood, Preston, Lancs., Chemist.
- O.M. Naylor, W. A. H., 38, Southwark Street, London, S.E., Manufacturing Chemist.
1899. Neate, Percy J., "Belsize," 5, Watts Avenue, Rochester, Kent, Director of Cement Co.
1902. Neave, Dr. Geo. B., Technical College, Montrose Street, Glasgow, Assistant to Professor of Chemistry.
1905. Neech, Herbert R., 20, Colegrave Street, Lincoln, Chemical Engineer.
1905. Needham, Edward R., 48, Paton Street, Glasgow, Manufacturing Chemist.
1905. Neff, Robert W., 22, India Square, Boston, Mass., U.S.A., Chemical Manufacturer.
1906. Neil, Dr. Archibald A., 82, Eccles Old Road, Manchester, Chemical Engineer.
1898. Neil, Jas. Millar, 97, Ontario Street, Toronto, Canada, Technical Chemist.
1890. Neill, Geo. D., Drumslea, Greenock, N.B., Sugar Refiner.
1898. Neilson, Alex. McG., Umbilo, Durban, Natal, Analytical Chemist.
1903. Neiman, Howard S., 122, Hudson Street, New York City, U.S.A., Manufacturing Chemist.
1902. Neish, Dr. Arthur C., Columbia University, New York City, U.S.A., Chemist.
1897. Nelson, Walter, Emscote Mills, Warwick, Gelatin Manufacturer.
1906. Nestell, Raymond J., 237, Lenox Avenue, New York City, U.S.A., Analytical Chemist.
1901. Neufville, Dr. Rudolf de, c/o Metallurgische Gesellschaft, Frankfurt a/M., Germany.
1902. Neumann, Dr. Edgar, 7 and 8, Idol Lane, London, E.C.
1903. Neumann, Dr. Max, Capellenstrasse 51, Wiesbaden, Germany.
- O.M. Newall, F. S., Washington Station R.S.O., Co. Durham, Chemical Manufacturer.
1905. Newall, Joseph, Rosedale, Norman Road, Runcorn, Cheshire, Chemist.
1889. Newberry, Spencer B., Sandusky Portland Cement Co., Sandusky, Ohio, U.S.A., Manager.
1909. Newbert, Alonzo M., 88, Broad Street, Boston, Mass., U.S.A., Dyewood Extract Merchant.
- O.M. Newlands, B. E. R., 2, St. Dunstan's Hill, London, E.C., Analytical and Consulting Chemist.
- O.M. Newlands, W. P. R., 10, Crielade Avenue, Streatham Hill, S.W., Sugar Chemist.
- O.M. Newton, Jno., Manor Works, Rotherhithe New Road, London, S.E., Manure Manufacturer.
1901. Nibelius, Axel W. T., c/o Emporium Powder Co., Emporium, Pa., U.S.A., Chemist.
1904. Nichols, C. W., 25, Broad Street, New York City, U.S.A., Manufacturing Chemist.
1905. Nichols, E. Remington, 25, Broad Street, New York City, U.S.A., Treasurer (Nichols Chemical Co.).
1884. Nichols, J. A., Stanley Mount, New Mills, near Stockport, Teacher of Science.
1888. Nichols, Dr. Wm. H., 25, Broad Street, New York City, U.S.A., Chemical Manufacturer.
1905. Nichols, W. H., jun., 25, Broad Street, New York City, U.S.A., President, San Carlos Copper Co.

N

1904. Nicholson, Wilfred E., Hunslet Chemical Works, Leeds, Chemical Manufacturer.
1897. Nicholson, Wm. J., Ardeer, Stevenston, Ayrshire, N.B., Chemist.
1903. Nicoll, Frank, 238, Barnley Road, Acerington, Chemist.
1905. Nieghorn, Albert, c/o Canada Chemical Manufacturing Co., Toronto, Canada, Agent.
1900. Nield, J. H., c/o General Chemical Co., P.O. Box 8, Edgewater, N.J., U.S.A., Superintendent.
1906. Nielsen, Dr. Carl, Chemist.
1898. Nightscapes, Geo., 37, Jalland Street, Hull, Oil Merchant.
1899. Nihoul, Dr. Edw., Warenume, Belgium, Director of the Liège Tannery School.
- O.M. Nimmo, Jas., Penshurst, 8, Lawrence Road, South Norwood, S.E., Analytical Chemist.
1907. Nims, H. E., c/o The Fiberloid Co., Indian Orchard, Mass., U.S.A., Chemist.
1885. Nishigawa, T., 12, Yamamoto Dori, Nichome, Kobe, Japan, Director of Sulphuric Acid and Soda Works.
1898. Nishikawa, T., c/o Nippon Seimikaisha, Onoda, Nagato, Japan, Chemist.
1908. Noble, Sir Andrew, Bart., F.R.S., Jesmond Dene House, Newcastle-on-Tyne.
- O.M. Nölting, Dr. E., Ecole de Chimie, Mulhouse, Alsace, Germany, Professor of Chemistry.
1905. Norden, Julius, 44, Farringdon Street, London, E.C., Chemical Manufacturer.
- O.M. Norman, F. J., Lyndhurst, Higher Runcorn, Cheshire, Chemical Manufacturer.
1900. Norman, Geo. M., Chemist.
1892. Norman, J. T., 23, Leadenhall Street, London, E.C., Consulting Chemist.
1890. Norman-Bott, Dr. Wm., 16, St. Helen's Place, London, E.C., Consulting Chemist.
1898. Norris, Albert P., 760, Massachusetts Avenue, Cambridgeport, Mass., U.S.A., Assistant Chemist.
1908. Norris, Wm. H. H., 5, Moss Terrace, Warrington, Northwich, Chemist.
1902. North, Barker, 22, Horton Park Avenue, Bradford, Assistant Professor of Chemistry.
1903. North, Henry A., 427, Elm Street, Chicago, Ill., U.S.A., Chemist.
- O.M. Northing, J., The Murrrough, Wicklow, Ireland, Technical Chemist.
1905. Norton, Arthur L., 36, Purchase Street, Boston, Mass., U.S.A., Dyestuff Merchant.
1905. Norton, F. A., National Canners' Laboratory, Aspinwall, Pa., U.S.A., Chemist.
- O.M. Norton, Dr. S. A., 363, East Town Street, Columbus, Ohio, U.S.A., Professor of Chemistry (Ohio State University).
1887. Norton, Dr. T. H., c/o Wm. Bryce, 54, Lothian Street, Edinburgh, U.S. Consul.
1899. Noyes, Henry, c/o J. C. Lanyon and Sons, Coronation House, Lloyd's Avenue, London, E.C., Engineer.
1901. Noyes, Prof. Wm. A., University of Illinois, Urbana, Ill., U.S.A., Editor (J. Amer. Chem. Society).
- O
1905. Oakes, F. J., jun., 141, Milk Street, Boston, Mass., U.S.A., Secretary, Oakes Manufacturing Co.
1904. Oberländer, Dr. Otto, 29, Queen Street, London, E.C., Research and Consulting Chemist.
1904. O'Brien, Claude H., Mossman Mill, Port Douglas, North Queensland, Supervising Chemist.
1900. O'Brien, Frederick, 87, Dongola Road, Horfield, Bristol, Analytical Chemist.
1906. O'Brien, John W., c/o Grasselli Chemical Co., Grasselli, Ind., U.S.A., Foreman.
1905. Oburg, W. F., 33, Broad Street, Boston, Mass., U.S.A., Assistant Treasurer (Merrimac Chem. Co.).
1902. Oekel, Reinhold, Baesrode, chez Ternoude, Belgium, Technical Chemist.
1901. O'Connor, Chas. P., 7, Fairfield Street, Montclair, N.J., U.S.A., Analytical Chemist.
1908. O'Day, John, 32, India Street, Boston, Mass., U.S.A., Dyestuff and Chemical Merchant.
1887. Oddie, Jas., School of Mines, Ballarat, Australia, Chemical Lecturer.
1888. Oddy, Robert W., Abbey Street, Toad Lane, Rochdale, Chemist.
1888. Ogata, Saburo, Nippon Ginko, Tokyo, Japan, Assayer.
1901. Ogden, Richard L., 314, North Main Street, Bethlehem, Pa., U.S.A., Chemist (U.S. Navy).
1906. Ogilvie, Alex. M., 9, Belmont Drive, Giffnock, Renfrewshire.
1908. Ogilvie, Jas. P., c/o Newlands Bros., 2, St. Dunstan's Hill, London, E.C., Chemist.
1896. Ogilvy, D. J., 1403, State Avenue, Cincinnati, Ohio, U.S.A., Manufacturing Chemist.
1901. Ogston, Alex. G., Heath Park, near Aberdeen, N.B., Soap Manufacturer.
1903. Ohlenschläger, J. G., jun., Shanghai House, Botolph Lane, London, E.C., Chemical Merchant.
1905. Ohliger, Willard, c/o F. Stearns & Co., Detroit, Mich., U.S.A., Chemist.
1909. Oilar, Rozier D., 68, Highwood Terrace, Weehawken, N.J., U.S.A., Cotton Seed Products Chemist.
1907. Oke, Alfred W., Orierton, 32, Denmark Villas, Hove, Sussex, Solicitor.
1884. Oliver, F., 31, Horsley Hill Road, Westoe, South Shields, Analytical Chemist.
1888. Oliver, Wm. Letts, 101, Vernon Street, Oakland, Cal., U.S.A., Mining Engineer.
1901. Olivier, Dr. Louis, 18, Rue Chauveau-Legarde, Paris, 8^e, Director (Revue Générale des Sciences).
1905. Ollenbach, D. S., Cordite Factory, Aruvankad, Nilgiris, India, Assistant Government Surgeon.
- O.M. Ollerenshaw, S., 96, Davyhulme Lane, Urmston, Manchester, Technical Chemist.
1906. Olmsted, Fred. A., 93, Broad Street, Boston, Mass., U.S.A., Chemical Engineer.
1904. Olney, L. A., 118, Riverside Street, Lowell, Mass., U.S.A., Professor of Chemistry and Dyeing.
1904. Olshausen, B. A., 1505, St. Andrew's Place, Los Angeles, Cal., U.S.A., Chemist.
1902. O'Neill, Chas., c/o Bleachers' Association, Ltd., 4, Norfolk Street, Manchester, Chemist and Colourist.
1907. Oppen, Wm. A., Vera Chemical Co., Stoneham, Mass., U.S.A., Chemist and Superintendent.
1898. Ormerod, Dr. Ernest, Star Life Buildings, 30, Cross Street, Manchester, Consulting Chemist.
1894. Ormerod, John, Globe Leather Works, Castleton, Manchester, Tanner and Currier.
- O.M. Orr, A., 35A, Bligh Street, Sydney, New South Wales, Analytical Chemist.
- O.M. Orr, J. B., Crossacres, Woolton, Liverpool, Chemical Manufacturer.
1899. Orr, Thos. W., Esperanza Nitrate Co., Taltal, Chile, and (communications), c/o W. Orr, 50, Wellington Street, Glasgow, Chemist.
1907. Ortvad, Niels C., c/o Hiram Walker & Sons, Ltd., Walkerville, Ont., Canada, Chemist and Fermentologist.
1900. Osbourne, Jno. P., 6, Garrioch Drive, Maryhill, Glasgow, Analytical Chemist.
1900. O'Shaughnessy, Francis R., Ilomo Farm, Tyburn, Birmingham, Chemist.
1885. O'Shea, Prof. L. T., Dept. of Applied Science, St. George's Square, Sheffield, Professor of Applied Chemistry (University of Sheffield).
1908. Osland, Clarence R., c/o R. W. Hunt and Co., 614, Canadian Express Building, Montreal, Canada, Chemist.
1883. O'Sullivan, J., High Bank, Burton-on-Trent, Brewing Chemist.
1905. Otsuki, Prof. Chiri, 16, Shinsuwachō, Koishikawa-ku, Tokyo, Japan, Professor of Applied Chemistry.
1898. Oushkoff, John P., c/o P. K. Oushkoff and Co., Moscow, Russia, Chemical Manufacturer.

1904. Owen, Halsall, Newholme, Latchford; and (Journals) c/o W. H. Smith and Son, 76, Sankey Street, Warrington, Engineer.
1906. Oxley, Horace F., c/o British Algin Co., and (Journals) Bryn Derwen, Holywell, North Wales, Chemist.
1908. Oxley, John C., Kelcliffe House, Guiseley, near Leeds, Aniline Colour Merchant.
1903. Ozias, Ramon E., 732, Clinton Avenue, Newark, N.J., U.S.A., Assayer.

P

1904. Packard, C. T., Millbank, Bramford, near Ipswich, Manager of Chemical Works.
- O.M. Packard, E., jun., Bramford, near Ipswich, Manure Manufacturer.
1904. Page, Edwin P., 31, Market Street, Stourbridge, Worcestershire, Chemist.
1886. Pagès, Albert, 34, Boulevard Henri IV., Paris, Technical Chemist.
1892. Paine, Augustus G., 41, Park Row, New York City, U.S.A., President of Paper Making Co.
1906. Palm, Otto G., 41, Colborne Street, Toronto, Canada, President (Atteaux Dye and Chemical Co.).
1903. Palmenburg, O. W., 80, St. Nicholas Avenue, New York City, U.S.A., Chemist.
1902. Palmer, Fred. G., Athelstan Road, Faversham, Kent, Analyst.
1887. Palmer, T. Chalkley, c/o American Dyewood Co., Chester, Pa., U.S.A., Manufacturing Chemist.
1887. Palmer, Thos. C., 98, Commercial Road East, London, E.; and (Journals) Westlington, Hatch End, Middlesex, Engineer.
1907. Palmer, Wm. J., c/o United Turkey Red Co., Ltd., Alexandria, N.B., Analytical Chemist.
1906. Papazzoni, Chas. F., c/o Keystone Powder Manufacturing Co., Box 314, Emporium, Pa., U.S.A., Chemist.
1906. Parke, Jas., Sturgeon Falls, Ont., Canada, Chemist.
1888. Parker, Chas. E., Penketh, Warrington, Tanner.
1898. Parker, Charles H., 106, Tottenhall Road, Wolverhampton, and (Journals) c/o British Coalite Co., Ltd., Wednesfield, Staffs., Chemist.
1891. Parker, Edw., Laburnum House, Rushford Park, Levenshulme, Manchester, Analytical Chemist.
1906. Parker, Elias G., 238, Grafton Avenue, Newark, N.J., U.S.A., Chemist.
1894. Parker, Dr. J. Gordon, Herold's Institute, Drummond Road, Bermondsey, S.E., Head of Tanning School.
1897. Parker, Prof. Matthew A., University of Manitoba, Winnipeg, Canada, Professor of Chemistry.
1901. Parker, Richard H., 231, West 134th Street, New York City, U.S.A., Analytical Chemist.
- O.M. Parker, Thos., Severn House, Ironbridge, Salop, Electrical Engineer.
1894. Parker, Thos. J., 25, Broad Street, New York City; and (Journals) Bayonne, N.J., U.S.A., Chemical Works Manager.
1903. Parker, Wm. B., 96, Murray Road, Rugby, Chief Chemist (British Thomson-Houston Co., Ltd.).
1901. Parker, Dr. Wm. Huntington, 177, State Street, Boston, Mass., U.S.A., Chemist (U.S. Appraisers).
1901. Parkes, Albert E., 43, Whitehorse Street, Stepney, E., Analytical Chemist.
1905. Parr, Prof. S. W., University of Illinois, Urbana, Ill., U.S.A., Professor of Applied Chemistry.
1898. Parrish, Saml., 80, Grange Avenue, Chapeltown Road, Leeds, Teacher of Chemistry.
1901. Pass, James, Onondaga Pottery Co., Syracuse, N.Y., U.S.A., Pottery Manufacturer.
1909. Passmore, Dr. Francis W., 63, Queen Victoria Street, London, E.C., Consulting Chemist.
1902. Patch, Prof. Jas. A., Syrian Protestant College, Beirut, Syria, Professor of Chemistry.
1897. Patehett, Col. Jas., Oakworth, Hadley, Wellington, Salop, Ironmaster.
1884. Paterson, John, Belle Isle Place, Workington, Cumberland, Mechanical Engineer.
1887. Paton, J. M. C., Messrs. Manlove, Alcott and Co., Ltd., Nottingham, Mechanical Engineer.
1886. Paton, W. Grant, Airlie, Huyton, near Liverpool, Alkali Works Manager.
1901. Patterson, Chas. A., c/o E. I. du Pont de Nemours Powder Co., Pinole, Cal., U.S.A., Analytical Chemist.
- O.M. Patterson, Geo., c/o The Manbré Saccharine Co., Ltd., Fulham Palace Road, Hammersmith, W., Technical Chemist.
1893. Patterson, Harry J., College Park, Prince George's Co., Md., U.S.A., Agricultural Chemist.
- O.M. Patterson, T. L., Maybank, Finnart Street, Greenock, N.B., Sugar Works Manager.
1902. Patterson, Wm. Hamilton, Heriot Watt College, Edinburgh, Technical Chemist.
- O.M. Pattinson, John, 10, Dean Street, Newcastle-on-Tyne, Consulting Chemist.
- O.M. Pattison, Jas., Drimnamona, Kilmalcolm, N.B., Chemical Merchant.
1889. Pattison, Percy J., St. Budeaux, Devonshire Road, Hornchurch, Essex, Technical Chemist.
1909. Patton, H. G., c/o Fred. Rueping Leather Co., Fond du Lac, Wis., U.S.A., Chemist.
1904. Patz, E. O., 215, Water Street, New York City, U.S.A., Manager, Berlin Aniline Works.
1908. Paul, David M., c/o Curtis and Harvey, Ltd., Cliffe at Hoo, Kent, Explosives Chemist.
1891. Paul, Jas. H., 11, Glenluce Road, Blackheath, S.E., Analytical Chemist.
1900. Paul, Dr. L. Gordon, Market Hall Chambers, King Street, Huddersfield, Consulting Chemist.
1904. Payne, A. G. C., 63, Plassey Street, Penarth, near Cardiff, Chemist.
- O.M. Payne, J. B., 13, Mosley Street, Newcastle-on-Tyne, Manufacturing Chemist.
1906. Payne, J. H., Box 153, Fordwick, Va., U.S.A., Chemical Engineer.
1898. Pearce, Edw. D., Messrs. T. P. Shepard and Co., P.O. Box 977, Providence, R.I., U.S.A., Manufacturing Chemist.
1894. Pearce, Jas. Stanley, Clements, Snaresbrook, Essex, Chemical Manufacturer.
1897. Pearce, Richard, Eddlewood, Weybridge, Surrey, Metallurgist.
1883. Pearce, W. M.P., Chemical Works, Bow Common, London, E., Chemical Manufacturer.
1903. Pearcey, A. C., 8, Albemarle Mansions, Hampstead, N.W., Director, Explosives Co.
1903. Pears, Thos., The Laboratory, Soap Works, Isleworth, Soap Manufacturer.
1904. Pease, Fred N., P.O. Box 503, Altoona, Pa., U.S.A., Chemist.
- O.M. Pechiney, A. R., Villa Les Roehers, Hyères (Var), France, Chemical Engineer.
1898. Peek, Dr. Ernest L., 18, Woodhey Road, Rock Ferry, Cheshire, Chemist.
1898. Peckham, Stephen F., 127, Franklin Street, New York City, U.S.A., Chemist.
1894. Peden, Jno., 30, Ardgowan Street West, Greenock, N.B., Analytical Chemist.
- O.M. Pedler, Sir Alexander, C.I.E., F.R.S., 28, Stanhope Gardens, Queen's Gate, London, S.W., Director of Public Instruction (retired).
1886. Pedler, J. R., 47, Tregunter Road, South Kensington, S.W., Clerk.
1905. Peet, Wm. J., Stockyards Station, Kansas City, Kas., U.S.A., Superintendent.
1903. Pepper, Harry C., c/o Aluminium Co. of America, East St. Louis, Ill., U.S.A., Manufacturing Chemist.
1906. Peile, Henry, Millburn House, Newcastle-on-Tyne, and (Journals) c/o Andrew Short, Patent Ovens Dept., Ottovale, Blaydon-on-Tyne, Colliery Owner.
1899. Pell, A., 7, Elphinstone Circle, Bombay, India, Chemist.
1897. Pellaw, Chas. E., Columbia University, New York City, U.S.A., Adjunct Professor of Chemistry.
1904. Pelly, Russell George, 63, Rowan Road, Brook Green, Hammersmith, W., Analytical Chemist.
1896. Penney, Mulgrave D., 11, High Street, Hull, Analytical Chemist.

1890. Pennock, J. D., c/o Solvay Process Co., Syracuse, N.Y., U.S.A., Technical Chemist.
1906. Pennymore, Percy G., Runswick, Dudley Road, Brierley Hill, Staffordshire, Chemist and Blast Furnace Manager.
1885. Pentecost, S. J., Alexandra Mount, Mapperley Hill, and (Journals), Sherwood Hill Works, Sherwood Rise, Nottingham, Lace Dresser.
1887. Pentermann, H. T., 37, Clifton Crescent, Peckham, S.E., Brewing Chemist.
1892. Peploe, D. H. T., Underriver House, Sevenoaks, Kent.
1899. Peppel, S. Vernon, 1538, North High Street, Columbus, Ohio, U.S.A., Chemist.
1885. Perkin, A. G., F.R.S., Grosvenor Lodge, Grosvenor Road, Leeds, Technical Chemist.
1898. Perkin, Dr. F. Mollwo, Borough Polytechnic Institute, Borough Road, S.E., Head of Chemical Department.
1887. Perkin, Dr. W. H., F.R.S., Fairview, Wilbraham Road, Fallowfield, Manchester, Professor of Chemistry.
1903. Perkins, Frank G., 211, North La Fayette Street, South Bend, Ind., U.S.A., Starch Manufacturer.
1893. Perkins, T. S., 30, Tiffany Place, Brooklyn, N.Y., U.S.A., Chemist.
1899. Perks, Walter G., Rothsay, Teddington Park, Teddington, S.W., Manufacturer.
1906. Perrow, Mosley G., Lynchburg, Va., U.S.A.
1901. Perry, Chas. M., Greene, Kent County, R.I., U.S.A., Bleach and Dyeworks Chemist.
1887. Perry, D., Norwood, Lenzie, N.B., Manufacturing Chemist.
1895. Perry, Jos. H., 276, Highland Street, Worcester, Mass., U.S.A., Teacher of Chemistry.
1903. Perry, M. J. T., Australian Drug Co., O'Connell Street, Sydney, N.S.W., Australia, Manufacturing Chemist.
1903. Perry, Robt. Swain, c/o Harrison Bros. and Co., Inc., 35th Street and Grays Ferry Road, and (Journals) Station D., Philadelphia, Pa., U.S.A., President.
1901. Persons, Ashton C., 74, Oak Street, Willimantic, Conn., U.S.A., Chemist.
1897. Peter, Dr. A. H., Hastings on Hudson, N.Y., U.S.A., Chemist.
1908. Peters, John M., 184, Front Street, New York City, U.S.A., White Lead Manufacturer.
1893. Pethybridge, Walter, 3, Rhodesia Road, Clapham Rise, S.W., Chemist and Assayer.
1909. Petrie, A. Swanston, c/o Gibbs and Co., Iquique, Chile, S. America, Anal. Chemist.
1903. Petrie, Dr. Jas. M., The University, Sydney, N.S.W., Australia, Chemist.
1902. Petsche, B. W., 60, Glenwood Avenue, Yonkers, N.Y., U.S.A., Chemist.
1906. Pettee, Chas. L. W., c/o Hartford Laboratory Co., Hartford, Conn., U.S.A., Chemist.
1892. Pettigrew, Robert, c/o Mersey and Irwell Joint Committee, 44, Mosley Street, Manchester, Electro-Chemist.
1902. Pettitt, Alf., 457, State Street, Brooklyn, N.Y., U.S.A., Chemist.
1906. Peuchen, Arthur G., Standard Chemical Co., Ltd., 509, Manning Chambers, Toronto, Canada, Chemical Manufacturer.
1905. Peuchot, A., 129, Crosby Street, New York City, U.S.A., Chemical Manufacturer.
- O.M. Peyton, E. P., Chemical Works, Lister Street, Birmingham, Chemical Manufacturer.
1900. Peyton, Wm. C., c/o Peyton Chemical Co., Room 657, Mills Building, San Francisco, Cal., U.S.A., Chemist.
1888. Philip, Arnold, Chemical Laboratory, H.M. Dockyard, Portsmouth, Electro-Metallurgist and Electrical Engineer.
1908. Philip, Dr. James C., Imperial College of Science and Technology, Stn. Kensington, S.W., Chemist.
1903. Philipp, Herbert, 84, High Street, Perth Amboy, N.J., U.S.A., Chemist and Electrochemical Engineer.
1886. Phillips, A. G., 11, Essex Villas, Phillimore Gardens, Kensington, W., Barrister-at-Law.
1891. Phillips, G. Brinton, (Journals) 622, Rose Street; and (communications) 2007, De Lancey Place, Philadelphia, Pa., U.S.A., Manufacturing Chemist.
- O.M. Phillips, Hareourt, Lynwood, Turton, Lancs., Analytical Chemist.
1895. Phillips, S. Chas., 47, Cannon Street, London, E.C., Chemical Engineer.
1904. Phillips, V. C., c/o Brotherton and Co., Ltd., Haigh Park Chemical Works, Leeds, Chemist.
1898. Phillips, Wm. H., 100, Milton Avenue, East Ham, E., Soap Works Chemist.
1894. Picard, Hugh F. K., 44, London Wall, London, E.C., Metallurgist.
1907. Pick, Dr. Hans, c/o Compagnie Liebig, Longue Rue des Claires, Antwerp, Belgium, Analytical Chemist.
1904. Pickard, Glenn H., c/o The Spencer-Kellogg Co., Buffalo, N.Y., U.S.A., Chemist.
1905. Pickard, Greenleaf W., Amesbury, Mass., U.S.A., Electrical Engineer.
1902. Pickard, R. H., Isca, Merlin Road, Blackburn, Teacher and Analyst.
1904. Pickett, Chas. E., 26, East 33rd Street, Bayonne, N.J., U.S.A., Superintendent, Borax Refinery.
1904. Pickup, Edgar H., 348, Great Clowes Street, Higher Broughton, Manchester, Calico Printer.
1888. Pilkington, G., 9, Knowsley Street, Bury, Lancashire, Analytical Chemist.
1893. Pilley, Thos. W., 33, Grove Hill Road, Denmark Hill, S.E., Analytical Chemist.
1894. Pilling, John E., 229, Hornby Road, Blackpool, Chemist.
1906. Pineott, Emile S., 222, St. James Street, Montreal, Canada, Manager (Nichols Chemical Co. of Canada, Ltd.).
1905. Pinnock, H. T., 29, Victoria Road, Tipton, Staffs., Chemist.
1883. Pipe, Jas., Woodburn, Irvine, N.B., Chemical Manufacturer.
1896. Piper, Walter E., Boston Rubber Shoe Co., Malden, Mass., U.S.A., Chemist.
1907. Pitman, Brig.-Gen. John, 167, Berkeley Avenue, Orange, N.J., U.S.A., U.S. Army (retired).
- O.M. Pitt, T., c/o Burgoyne and Co., High Street South, East Ham, E., Manufacturing Chemist.
1902. Pittard, Jno., 30, Mansfield Road, Hford, Essex, Chemical Manufacturer.
1884. Pittuck, F. W., 19, Stratford Grove, Heaton, Newcastle-on-Tyne, Technical Chemist.
1899. Pizey, Jas. H., Bella Vista 19, Minas de Rio Tinto, Prov. de Huelva, Spain, Chemist.
1894. Platten, Frank, 12, Montague Road, Edgbaston, Birmingham, Metallurgical Chemist.
1890. Platts, Jno. C., 12, Alton Terrace, Fairfield, Manchester, Metallurgical Chemist.
1896. Plaut, Albert, 120-128, William Street, New York City, U.S.A., Wholesale Druggist.
1888. Playfair, David J., 7, Victoria Crescent, Dowanhill, Glasgow, Manufacturing Chemist.
1907. Playter, Geo. H., 803, Beacon Building, Boston, Mass., U.S.A., Mining Engineer.
1908. Plows, G. H., 14, Regent Park Avenue, Headingley, Leeds, Tar Distiller.
1891. Pocklington, Hy., 11, Regent Park Terrace, Leeds.
1907. Poetschke, Paul, 26, West Spruce Street, Corona, N.Y., U.S.A., Chemist.
1901. Pollard, Wm., Museum, Jermyn Street, London, S.W., Chemist (H.M. Geological Survey).
1904. Pollitt, Dr. Geo. P., Winnington, Northwich, Cheshire, Chemist.
1902. Pollitt, Jas. C. T., 7, Grosvenor Road, Handsworth, Birmingham, Managing Chemist.
1893. Pollitt, R. B., c/o Compania Nacional de Dinamita y Explosivos, Dinamita (vía Noé), Durango, Mexico, Civil Engineer.
1883. Pollock, A., Kirkland, Bonhill, Dumbartonshire, Dyeworks Manager.
1890. Pomeroy, Dr. Chas. T., 55, Broad Street, Newark, N.J., U.S.A., Ink Manufacturer.

1909. Pond, Francis J., 86, Valley Road, Montclair, N.J., U.S.A., Assoc. Professor of Chemistry.
1896. Pond, Prof. G. G., State College, Centre Co., Pa., U.S.A., Professor of Chemistry.
- O.M. Pond, J. A., 99, Queen Street, Auckland, New Zealand, Analytical Chemist.
1906. Pont, A. Felix du, Box 31, Wilmington, Del., U.S.A., Explosives Manufacturer.
1895. Pont, Pierre S. du, Wilmington, Del., U.S.A., Explosives Manufacturer.
- O.M. Pope, S., 6, Heywood Street, Moss Side, Manchester, Chemical Works Manager.
1899. Pope, Thos. H., The University, Birmingham, Chemist.
1900. Pope, Prof. W. J., F.R.S., University Chemical Laboratory, Cambridge, Professor of Chemistry.
1900. Popplewell, Jos. M., Provan Chemical Works, Provanmill, Glasgow, Chemist.
1899. Porter, A. Felix, c/o E. I. du Pont de Nemours Powder Co., Haskell, N.J., U.S.A., Superintendent.
1908. Porter, A. Harold, 1417, Sixth Street, S.E., Minneapolis, Minn., U.S.A., Chemist.
1902. Porter, J. Edw., P.O. Box 785, and 205, W. Genesee Street, Syracuse, N.Y., U.S.A., Chemist.
1901. Porter, Jno. L., Water Purification Station, P.O. Box 791, Station B, New Orleans, La., U.S.A., Chemist.
1884. Potter Chas. E., Love Lane Sugar Refinery, Liverpool, Sugar Works Chemist.
1905. Potter, Chas. Ed., c/o City Dairy Co., Ltd., Spadina Crescent, Toronto, Canada, General Manager.
1888. Potter, Chas. J., Heaton Hall, Newcastle-on-Tyne, Cement Manufacturer.
- O.M. Potter, E. P., Salwick Hall, near Preston, and (Journals) c/o E. P. Potter and Co., Ltd., Little Lever, near Bolton, Alkali Manufacturer.
1906. Potter, Dr. H. Noel, Hollywood, Cal., U.S.A., Electrical Engineer.
1899. Potter, Rowland S., c/o Defender Dry Plate Co., Germantown, Philadelphia, Pa., U.S.A., Chemist.
1900. Potts, Geo. E., 18, Tremont Street, Pottsville, Pa., U.S.A., Explosives Manufacturer.
1900. Pough, Frank H., (subs.) 82, Beaver Street, New York City, and (Journals) 149, Columbia Heights, Brooklyn, N.Y., U.S.A., Assistant Secretary.
1900. Powell, Harry J., 125, Thurlow Park Road, Dulwich, S.E., Glass Manufacturer.
1884. Powell, L. S., The Old Manor House, Ashley, Stockbridge, Hants, Electrician.
1897. Power, Dr. Fred. B., Wellcome Research Laboratories, 6, King Street, Snow Hill, London, E.C., Director.
1907. Powers, Wm. R., c/o A. T. and S. F. R. R. Co., Topeka, Kans., U.S.A., Chief Chemist.
1902. Powney, Wm. E. F., 7, Mandalay Road, Clapham Common, S.W., Analytical Chemist.
1897. Prentice, Dr. Bertram, Royal Technical Institute, Salford, Lecturer on Chemistry.
1902. Prentice, Dr. David, The Nook, Whitefield Road, Stockton Heath, Warrington, Chemist.
1903. Prentice, Jas., Cossipore Sugar Works, Cossipore, Calcutta, India, Chemist.
1905. Prentiss, G. L., c/o Parson Manufacturing Co., 299, Broadway, New York City, U.S.A., Treasurer.
1900. Prescott, Saml. C., 739, Boylston Street, Boston, Mass., U.S.A., Instructor in Bacteriology.
1905. Preston, Jas. F., Lowell, Mass., U.S.A., Manufacturing Chemist.
1906. Preston-Jackson, J. W. A., Castleford, Yorkshire, Consulting and Analytical Chemist and Druggist.
- O.M. Price, Arthur F., 2503, Broadway, San Francisco, Cal., U.S.A., Analytical Chemist.
1905. Price, Dr. T. Slater, The Technical School, Birmingham, Lecturer on Chemistry.
1904. Pritchard, Norman B., 40, Quebec Street, Sherbrooke, Quebec, Canada, Superintendent.
1904. Prideaux, Dr. E. B. R., 17, Glengyle Terrace, and (Journals) Heriot Watt College, Edinburgh, Research Chemist.
1905. Priest, Geo. Wesley, Mansfield, Mass., U.S.A., Manufacturer.
1906. Pring, J. N., Physical Laboratories, University of Manchester, Student.
1899. Prinsen-Geerligs, H. C., Wanningstraat 17, Amsterdam, Holland, Director of Sugar Cane Experimental Station.
1893. Pritchard, Edgar J., 11, Cumberland Road, Kew, Surrey, Works Manager.
1903. Pritchard, Philip M., Chief Engineer's Office, United Alkali Co., Ltd., Widnes, Engineer.
1896. Prochazka, Dr. Geo. A., 138, West 13th Street, New York City, U.S.A., Colour Manufacturer.
- O.M. Procter, Prof. H. R., The University, Leeds; and (Journals) Rowangarth, Ben Rhydding, near Leeds, Lecturer on Tanning.
1884. Procter, J. W., Skeldergate Bridge, York, Manure Manufacturer.
1890. Procter, Miss Anne J., Free Library, Widnes, Librarian.
- O.M. Procter, C., 43A, London Road, Forest Hill, S.E., Analytical Chemist.
1901. Propach, C., 133, East Kinzie Street, Chicago, Ill., U.S.A., Colour Merchant.
1891. Proude, Jas., Providence Soap and Oil Works, Halifax, Yorks., Chemist and Manager.
1907. Pryce, Geo. A., c/o Philip Harris & Co., Ltd., 144 & 146, Edmund Street, Birmingham, Manager of Apparatus Department.
1907. Puckhaber, Geo. C., 805, Prospect Place, Brooklyn, N.Y., U.S.A., Glue Maker.
1906. Pudney, Sydney H., 156, Bellwood Avenue, Toronto, Canada, Foreman.
1905. Pugh, John V., Guiting House, Allesley, near Coventry, Works Director (Rudge Whitworth, Ltd.).
1899. Pullar, Edmund, Keirfield, Bridge of Allan, N.B., Manufacturer.
1894. Pullar, Herbert S., Pullar's Dyeworks, Perth, N.B., Dyer.
- O.M. Pullar, Sir Robert, M.P.; Journals to Jas. Craigie, Sandeman Public Library, Perth, N.B., Dyer.
- O.M. Pullar, R. D., Pullar's Dyeworks, Perth, N.B., Dyer.
1903. Pullin, Sydney R., c/o Palmarejo and Mexican Goldfields, Ltd., Chinipas, Chihuahua, Mexico, Chemist.
1902. Puntan, H. H. C., 10, London Chambers, Durban, Natal, Public Analyst.
1894. Purdie, Dr. Thos., F.R.S., 14, South Street, St. Andrews, N.B., Professor of Chemistry.
1905. Pyman, Dr. Frank Lee, Carlee, Selborne Road, Sideup, Kent, Chemist.
1908. Pyne, Albert R., 134, Carlton Street, Toronto, Canada, Chemist.

Q

1907. Quad, Louis J., P.O. Box 189, Edgewater, N.J., U.S.A., Chemist.
1903. Queeny, Jno. F., Monsanto Chemical Works, 1806-1818, South 2nd Street, St. Louis, Mo., U.S.A., Chemical Manufacturer.
1903. Queneau, Augustin L., c/o Wetherill Co., Erie Avenue, East of Erie Street, Philadelphia, Pa., U.S.A., Mining Engineer.
1887. Quibell, Oliver, Shalem Lodge, Newark-on-Trent, Manure Manufacturer.
1902. Quinan, Kenneth B., Cape Explosives Works, Somerset West, C.C., South Africa, Chemist.
1897. Quinan, Wm. R., (Journals) General Manager, Cape Explosives Works, Dynamite Factory, Cape Colony, South Africa; and (subscriptions) c/o Cape Explosives Works, Ltd., 15, St. Swithin's Lane, E.C., Superintendent (Powder Works).

R

1907. Rabino, Jos. F., Sugar Factory, Abou-Kourgas, Upper Egypt, Sugar Maker.
1898. Radcliffe, Lionel G., 929, Chester Road, Stretford, Manchester, Chemist.

1904. Rademacher, Dr. Ferdinand, Prag-Carolinenthal, Austria, Chemical Manufacturer.
1900. Radley, Ernest G., 49, Ernest Street, West Norwood, S.E.
1908. Rae, Robert, Poplar House, Ditton, near Widnes, Metallurgical Chemist.
1895. Raegenner, Louis C., 141, Broadway, New York City, U.S.A., Patent Lawyer.
1906. Raff, Dr. Albert K., Mosaic, Pa., U.S.A., Chemist.
1901. Ralston, Wm., 3, Windsor Terrace, Linthouse, Glasgow, Government Chemist.
1902. Ramsay, A. Alexander, Laboratory, Department of Agriculture, 136, George Street, Sydney, N.S.W., Australia, Assistant Chemist.
- O.M. Ramsay, Sir William, K.C.B., F.R.S., University College, London, W.C.; Journals to 19, Chester Terrace, N.W., Professor of Chemistry.
1885. Ramsay, W., c/o Cammell, Laird and Co., Ltd., Birkenhead Ironworks, Birkenhead, Chemist and Assayer.
1906. Ranek, Samuel H., Ryerson Public Library Building, Grand Rapids, Mich., U.S.A., Librarian.
1901. Ransom, Francis, The Chilterns, Hitchin, Herts., Manufacturing Pharmaceutical Chemist.
1905. Ransom, H. B., 28, Belsize Park Gardens, Hampstead, N.W., Engineer.
1904. Rapelje, Walter S., 568, Jamaica Avenue, Brooklyn, N.Y., U.S.A., Chemist.
1898. Raschen, Dr. Julius, The Highlands, Runcorn, Cheshire, Consulting Chemist (United Alkali Co.).
1905. Raschig, Dr. F., Ludwigshafen a/Rhein, Germany, Manufacturing Chemist.
1908. Rassow, Prof. Dr. Berthold, Dörrienstrasse 13, Leipzig, Germany, General Secretary, Vereins Deutscher Chemiker.
1893. Ratchiff, Frank D., Medina, Widney Road, Knowle, near Birmingham, Vinegar Brewer.
1904. Ratcliffe, C. F., Haigh Park Chemical Works, Stourton, near Leeds, Tar Distiller.
1904. Ratcliffe, Mrs. F. A., Haigh Park Chemical Works, Stourton near Leeds.
1898. Ratcliffe, Walter, 21, Mawdsley Street, Bolton, Analytical Chemist.
1895. Rau, Dr. H. M., 130-132, Pearl Street, New York City, U.S.A., Chemist.
1901. Rawlins, Herbert J. L., The Cottage, Rainhill, Lancashire, Managing Director.
1903. Rawolle, Frederick C., c/o Marx and Rawolle, 100, William Street, New York City, U.S.A., Chemist.
- O.M. Rawson, Chris., Battenberg Avenue, Leicester, Consulting Chemist.
1909. Rawson, H. Wyatt, St. Paul's College, University, Sydney, N.S.W.
1909. Rayner, Arthur B., c/o Haddock, Parker, and Co., 14, Chapel Street, Liverpool, Chemical Broker.
1895. Read, E. J., Portland, Belmont Road, Westgate-on-Sea, Analyst.
1890. Reade, Thos., 20, Harborne Road, Edgbaston, Birmingham, Manufacturing Chemist.
- O.M. Readman, Dr. J. B., Stafffield Hall, Kirkoswald, R.S.O., Cumberland, Analytical and Consulting Chemist.
1908. Reavell, J. Arthur, 181, Queen Victoria Street, London, E.C., Engineer.
1907. Rebhun, Frank E., c/o Pennsylvania Salt Manufacturing Co., Natrona, Pa., U.S.A., Chemist.
1902. Redfern, C. G., 4, South Street, Finsbury, London, E.C., Patent Agent.
1890. Redgate, J. G., Traffic Street, Nottingham, Aërated Water Manufacturer.
- O.M. Redwood, Sir Boverton, 4, Bishopsgate Street Within, London, E.C., Petroleum Expert.
1884. Redwood, Ilyd J., The Chestnuts, Erith Road, Bexley Heath, Kent, Technical Chemist.
1887. Redwood, Robt., 4, Bishopsgate Street Within, London, E.C., Secretary.
1891. Redwood, T. Horne, 2, West Ascent, St. Leonard's-on-Sea, Analytical Chemist.
1886. Rée, Dr. A., 15, Mauldeth Road, Withington, Manchester, Aniline Dye Manufacturer.
1884. Reed, Albert E., The Grange, Leigham Court Road, Streatham, S.W., Paper Works Chemist.
1902. Reed, Herbert C., c/o Stamford Manufacturing Co., Stamford, Conn., U.S.A., Chemist.
1895. Reed, Dr. J. Hastings, Hambledon Mill, *via* Cairns, North Queensland, Sugar Manufacturer.
1906. Reed, William, Bridge House, Bridge Road, Millwall, E., Foreman (Desilverising Works).
1893. Reekie, J. A., Woodhouse, Hayfield, Derbyshire, Calico Printer's Colour Mixer.
1883. Reeks, T. H., 106, Queen Victoria Street, London, E.C., Analytical and Consulting Chemist.
1897. Rees, W. H., c/o Alameda Sugar Co., Alvarado, Cal., U.S.A., Chemist.
1906. Rees, Walter J., c/o Chance Bros. and Co., Ltd., Smethwick, near Birmingham, Glass Works Chemist.
1900. Reese, Dr. Chas. L., Eastern Laboratory, P.O. Box 424, Chester, Pa., U.S.A., Chemist.
1897. Reid, Andrew, c/o L. and J. McLellan, 65, Port Dundas Road, Glasgow, Chemist.
1908. Reid, George, 72, Park Drive South, Whiteinch, Glasgow, Analyst.
1906. Reid, James, Moffat Mills, Airdrie, N.B., Chemist.
1905. Reid, Dr. John H., 11, Glover Street, Birkenhead, Chemist.
1907. Reid, Robert, Agencia de Tharsis, Huelva, Spain, Analytical Chemist.
1896. Reid, Robt., Oil Mills, Horbury Bridge, near Wakefield, Chemist.
- O.M. Reid, Walter F., Fieldside, Addlestone, Surrey, Technical Chemist.
1893. Reid, Wm., jun., Bombay Dyeworks, Dadur, Bombay, India, Dyer.
1907. Reimarus, Dr. C., Chemische Fabrik auf Actien (vorm. E. Schering), Müllerstrasse 170, Berlin, N., Germany, Manager.
1904. Reinherz, Otto, 9, Heaton Grove, Bradford, Yorks., Chemist.
1906. Reinhold, Gustave, 11, Hervey Road, Blackheath, S.E., Works Manager.
1898. Reitmeyer, Robt. E. D., 63, Crutched Friars, London, E.C., Chemical Merchant.
1904. Remington, Prof. Joseph P., 1832, Pine Street, Philadelphia, Pa., U.S.A., Author, U.S. Pharmacopœia.
1900. Remington, J. Stewart, Aynsome, Grange-over-Sands, R.S.O., Lanes., Consulting Chemist.
1903. Remsen, President Ira, Johns Hopkins University, Baltimore, Md., U.S.A., President.
1884. Renaut, F. W., 5, Elers Road, Ealing, W., Secretary.
- O.M. Rennie, Dr. E. H., University of Adelaide, South Australia, Professor of Chemistry.
1901. Renwick, Frank F., Norland House, Avenue Road, Brentwood, Essex, Chemist (Photographic Works).
1907. Reoch, Robert A. S., Cochecco Manufacturing Co., Dover, N.H., U.S.A., Printworks Superintendent.
1894. Rettie, Theodore, 16, Great King Street, Edinburgh, Metallurgical Chemist.
1895. Reubens, Chas. M., 148, West 111th Street, New York City, U.S.A., Chemist.
1905. Revis, Cecil, 7, Beverley Road, Barnes, S.W., Analyst.
- O.M. Reynolds, Dr. J. Emerson, F.R.S., 7, Grenville Place, South Kensington, S.W., Professor of Chemistry.
1904. Rhett, Edmund, c/o Virginia-Carolina Chemical Co., Durham, N.C., U.S.A., Works Manager.
1908. Rhoads, J. Edgar, Box 961, Wilmington, Del., U.S.A., Leather Chemist.
- O.M. Rhodes, E., c/o Thos. Vickers and Sons, Widnes, Technical Chemist.
1892. Rhodes, P. J., Bridge House, Church, Accrington, Dye and Print Works Manager.
1889. Richards, Edgar, 60, Ayrault Street, Newport, R.I., U.S.A., Analytical Chemist.
1888. Richardson, Dr. Clifford, 30, Church Street, New York City, U.S.A., Chemical Engineer.
1903. Richardson, F. J., Chemical Works, Ringsend Docks, Dublin, Ireland, Chemical Manure Manufacturer.

1884. Richardson, F. W., City Analyst's Office, Bradford ; and (Journals) Oak Lea, Menston-in-Wharfedale, Yorkshire, Analytical Chemist.
1900. Richardson, Jno. H., c/o H. D. Pochin and Co., Ltd., Salford, Manchester, Manager.
1905. Richardson, L. G., Russell Buildings, 10, Leeds Road, Bradford, Yorks., Chemist.
1889. Richardson, S. M., 415, Main Street, Bonhill, N.B., Analytical Chemist.
1891. Richardson, Walter W., Aldingham, Park View Crescent, Roundhay, Leeds, Manufacturing Chemist.
1903. Richardson, Wm., 2, Thonfield Road, West Park, Haddingley, Leeds, Drysalter.
1894. Richardson, Wm. H., Newsky Thread Mills, Malaja, Bolotnaja, St. Petersburg, Russia, Textile Chemist.
1904. Richardson, Wm. S., 201, High Street, Lincoln, Chemical Manure Manufacturer.
1886. Richmond, H. D., 39, Woodfield Road, Ealing, W., Chief Chemist (Aylesbury Dairy Co.).
1898. Richmond, Jno. E., 14, North Road, West Kirby, Cheshire, Alkali Works Manager.
1901. Richmond, Sylvester O., Royal William Yard, Plymouth, Analytical Chemist.
1907. Ricketts, Guy D., *See* Bengough, Guy D.
1886. Riddell, R., 87, Horninglow Street, Burton-on-Trent, Brewer.
1894. Ridding, Howard C., School of Mines, Clinton Road, Redruth, Cornwall, Principal.
1884. Rideal, Dr. Samuel, Laboratory, 28, Victoria Street, Westminster, S.W., Consulting Chemist.
1905. Ridge, H. M., Owtor Manor, Seaton Carew, Co. Durham, Mining Engineer.
- O.M. Ridsdale, C. H., Ravenscroft, Roman Road, Linthorpe, Middlesbrough, Analytical Chemist.
1899. Riederer, Emil J., c/o Eastern Dynamite Co., Forcite Works, Landing, N.J., U.S.A., Works Chemist.
1902. Riederer, Dr. Herman S., c/o Morris Herrmann and Co., 878, Mount Prospect Avenue, Newark, N.J., U.S.A., Chemist.
1908. Rigby, Wm. T., County Analyst's Laboratory, Temple Street, Birmingham, Public Analyst.
1907. Rigg, Gilbert, c/o New Jersey Zinc Co., Palmerton, Carbon Co., Pa., U.S.A., Chemist.
1892. Riker, Jno. J., 46, Cedar Street, New York City, U.S.A., Merchant.
- O.M. Riley, E., 2, City Road, Finsbury Square, London, E.C., Metallurgical Chemist.
- O.M. Riley, J. E., c/o John Riley & Sons, Hapton, near Accrington, Chemical Manufacturer.
1905. Riley, Louis J., 8, Newton Road, London, W., Chemist.
1899. Rink, Arnold, 11, Bridgewater Street, Barbican, London, E.C., Tannin Extract Manufacturer.
1889. Rintoul, Wm., 4, Sewardstone Road, Waltham Abbey, Essex, Explosives Chemist.
1901. Ripley, Philip F., 48, Central Street, Andover, Mass., U.S.A., Chemist.
1909. Rising, Albert E., c/o General Chemical Co., 25, Broad Street, New York City, U.S.A., Manufacturing Chemist.
- O.M. Rix, W. P., Froester House, Kinglake Road, Egremont, Cheshire, Potter.
1907. Roberts, Chester, Swarthmore College, Swarthmore, Pa., U.S.A., Superintendent.
- O.M. Roberts, F. G., Adair, Oak Hill Lodge, Fognal, N.W., Chemical Manufacturer.
1901. Roberts, H. E. C., c/o British Explosives Synd., Pitsea, Essex, Chemist.
1907. Roberts, Percy R., c/o Blumenthal & Co., Wilmington, Del., U.S.A., Leather Chemist.
1885. Roberts, R. Wightwick, 22, Calle Arturo Prat, Valparaiso, Chili, Analytical and Consulting Chemist.
1900. Roberts, Wm. Brittain, Wilderspool House, Warrington, Brewer and Analyst.
1902. Roberts, Wm. H., 4, Sguall Street, Liverpool, Analytical Chemist.
1902. Robertshaw, Chas. D., c/o Chas. Price and Co., Oilworks, Belvedere, Kent, Analytical Chemist.
1891. Robertson, Alex. A., Riversdale, Cressington Park, Liverpool, Technical Chemist.
1897. Robertson, Andrew J., 2, North Ninth Street, Richmond, Va., U.S.A., Analytical Chemist.
1903. Robertson, Fred., The Hewan, Bearsden, Glasgow, Analytical Chemist.
1900. Robertson, Jas., Barneraig, South Medrox, by Glenboig, N.B., Analytical Chemist.
1891. Robertson, Dr. Robt., Research Dept., Royal Arsenal, Woolwich ; and (Journals) 29, Charlton Road, Blackheath, S.E., Analytical Chemist.
1897. Robinson, Clarence J., Westerleigh, West New Brighton, N.Y., U.S.A., Chemist.
1904. Robinson, Prof. Franklin C., Bowdoin College, Brunswick, Maine, U.S.A., Professor of Chemistry.
1902. Robinson, Hy., Fishwick, Culcheth Chemical Works, Newton Heath, Manchester, Manufacturing Chemist.
- O.M. Robinson, H. H., 75, Finborough Road, West Brompton, S.W., Analytical Chemist.
1907. Robinson, Herbert W., Robinson Bros., Ltd., Ryders Green, West Bromwich, Staffordshire, Tar Distiller.
- O.M. Robinson, Jno., 8, Albert Road, Widnes, Chemical Engineer.
- O.M. Robinson, Jos., Farnworth, Widnes, Chemical Manufacturer.
1887. Robinson, Thomas, (Journals) 401, West Street, Glasgow ; and (communications), The Villa, Nitschill, N.B., Chemical Works Manager.
1902. Robitschek, Carl, 200, Worth Street, New York City, U.S.A., Scientific Brewer.
1884. Rodger, Edw., 1, Clairmont Gardens, Glasgow, W.
1904. Rodger, Robert, Government Laboratory, Clement's Inn Passage, Strand, London, W.C., Chemist.
1905. Rodger, R. L., Suffolk House, Cannon Street, London, E.C., Manager (Peña Copper Mines).
1909. Rody, Franz A., Balbach Smelting and Refining Works, Newark, N.J., U.S.A., Chemist.
1904. Roeber, Dr. E. F., 239, West 39th Street, New York City, U.S.A., Editor, "Electrochemical Industry."
1903. Roelofsens, Dr. J. A., c/o Coal Distillation Co., Middlesbrough, Yorks., Works Manager.
1905. Rogers, Dr. Allen, Pratt Institute, Brooklyn, N.Y., U.S.A., Research Chemist.
1900. Rogers, Geo. J., Pembrey Copper Works, Burry Port, South Wales, Chemist.
1890. Rogers, Harry, 5, Stoke Newington Common, London, N.
1908. Rogers, Harry V., May Street, Ilkeston, Derbyshire, Engineer.
1907. Rogers, H. L., c/o Ingeniero Residente, Ferro Carril de Buenos Aires al Pacifico, 25 de Mayo 277, Buenos Aires, Argentina, Analyst and Cement Expert.
1899. Rogers, John, c/o Nobel's Explosives Co., Ltd., Nobel House, Glasgow, Chemist.
1907. Roller, Frank R., 525, 31st Street, Oakland, Cal., U.S.A., Powder Works Superintendent.
1898. Roller, H. C., 295, Ferry Street, Newark, N.J., U.S.A., Superintendent.
1899. Rollin, Chas., Bylton, East Jarrow-on-Tyne, Chemical Manufacturer.
- O.M. Rollin, J. C., 1, St. Nicholas Buildings, Newcastle-on-Tyne, Chemical Manufacturer.
1907. Rolph, George M., c/o California and Hawaiian Sugar Refining Co., Crockett, Cal., U.S.A., Sugar Refiner.
1905. Romanes, J. W., Casa Colon, Huelva, Spain, Chemical Engineer.
1898. Roode, Rudolf de, International Paper Co., Glens Falls, N.Y., U.S.A., Chemist and Superintendent.
- O.M. Roseoe, Sir Henry, F.R.S., 10, Bramham Gardens, South Kensington, S.W., Consulting Chemist.
1904. Rose, Jno., Wicken House, Stretton, near Warrington, Technical Chemist.
1901. Rose, Jno. Leonard, 45, De Parys Avenue, Bedford, Chemist.
1902. Rosebrugh, Prof. T. K., Professor of Electrical Engineering.

1897. Rosengarten, Dr. Geo. D., 1700, Fitzwater Street, Station D, Philadelphia, Pa., U.S.A., Manufacturing Chemist.
1896. Rosenheim, Dr. Otto, 68, Belsize Park Gardens, Hampstead, N.W., Research Chemist.
1887. Ross, Alex. J. J., Tayavalla, Falkirk, N.B., Chemical Manufacturer.
1893. Ross, Arthur, I, Glengall Road, Old Kent Road, London, S.E., Analytical Chemist.
1900. Ross, Raymond, Public Analyst's Office, Burnley, Lancashire, Analytical Chemist.
1906. Rossi, Auguste J., c/o Roessler Hasslacher Chemical Co., Perth Amboy, N.J., U.S.A., Mining Engineer.
1906. Rossi, Louis M., c/o Perth Amboy Chemical Works, Perth Amboy, N.J., U.S.A., Mining Engineer.
1906. Rossiter, E. C., 4, Park Road, West Smethwick, Birmingham, Chemical Engineer.
1888. Rothwell, C. F. Seymour, Photographic Works, Mobberley, Cheshire, Chemist.
1908. Rothwell, Herbert E., 241, Dunn Avenue, Toronto, Canada, Chemist.
1905. Rothwell, Robert R., 88, George Street, Moss Side, Manchester, Chemistry and Physics Teacher.
- O.M. Rottenburg, Paul, Castle Chambers, 55, West Regent Street, Glasgow, Chemical Merchant.
1899. Rouse, H. W., Anglo-Continental Guano Works, Victoria Docks, E., Foreman.
1903. Rouse, Wm., 25, Albert Street, Alexandria, Dumbartonshire, Chemist.
1906. Rowell, Herbert W., c/o Major and Co., Ltd., Seuloates, Hull, Analytical Chemist.
- O.M. Rowland, W. L., 4800, Chester Avenue, Philadelphia, Pa., U.S.A., Chemist.
1904. Rowley, Ernest W., Chemical Laboratory, Locomotive Department, North Eastern Railway, Gateshead-on-Tyne, Analytical Chemist.
1908. Rowley, Frank, 4, Doughty Street, London, W.C., Metallurgist.
1901. Rowley, Walter Eugene, c/o Schoellkopf, Hartford, and Hanna Co., 100, William Street, New York City, U.S.A., Chemist.
1904. Rowling, S. R., 1, Beechwood, Kendal, Westmoreland, Chemist.
1896. Royal-Dawson, H., 6, Wimbourne Road, Edgbaston, Birmingham, Chemist.
1898. Royle, Chas. L., Sugar Chemist.
- O.M. Royse, S. W., St. Andrew's Chambers, 20, Albert Square, Manchester, Chemical Engineer.
1902. Rücker, Dr. Hermann von, 103, Lancaster Avenue, Buffalo, N.Y., U.S.A., Chemist.
1896. Ruddock, Fred. G., Corporation Street, Warrington, Analytical Chemist.
1895. Rudge, Alfred, Sutton Alkali Works, St. Helens, Lanes., Analytical Chemist.
1908. Rudolf, Prof. Norman S., Dept. of Applied Chemistry, Indian Institute of Science, Bangalore, India, Professor.
1884. Ruffle, Jno., Musley, Ware, Herts., Consulting Chemist and Electrician.
1905. Rüger, Richard, 13, Balmoral Road, Fairfield, Liverpool, Chemist.
1898. Ruhl, Louis, c/o Roessler and Hasslacher Chemical Co., P.O. Box 1999, 100, William Street, New York City, U.S.A., Chemical Merchant.
- O.M. Rumble, C., Belmont Works, Battersea; and (Journals) 9, Sangora Road, New Wandsworth, London, S.W., Candle Works Chemist.
1899. Rumhold, Wm. R., c/o Hebburn and Son, Pancras Lane, Queen Victoria Street, London, E.C., Electro-Metallurgist.
1895. Rump, Ernest, The Leeds Phosphate Works, Hunslet, Leeds, Manager.
1903. Runting, D. A., Moreland Grove, Coburg, Melbourne, Vic., Australia, Assayer.
1903. Runyan, Elmer G., Hutchins Building, Washington, D.C., U.S.A., Chemist and Gas Inspector.
1899. Rushby, Wm., Oak View, Batley, Yorks., Analyst.
1906. Russell, David, Cadham, Markinch, Fife, Scotland, Paper Maker.
1908. Russell, Walter M., Office of Gas Inspector, City Hall, Dallas, Texas, U.S.A., Industrial Chemist.
- O.M. Russell, Dr. W. J., F.R.S., 31, Upper Hamilton Terrace, London, N.W., Professor of Chemistry.
1901. Rust, Robt. R., 312, West 97th Street, New York City, U.S.A., Chemist.
1905. Ryan, Prof. F. G., (Journals) c/o Parke, Davis and Co., Detroit, Mich., U.S.A., and (subscriptions) c/o Parke, Davis and Co., Beak Street, Regent Street, London, W., Manufacturing Chemist.

S

1895. Saalfeld, Adolphe, 2, South King Street, Manchester, Chemical Merchant.
1895. Saabach, Dr. L., 111, Pearl Street, New York City, U.S.A., Consulting Chemist.
1908. Sabbaton, Frederic A., c/o Laurentide Paper Co., Ltd., Grande Mère, P.Q., Canada, Paper Manufacturer.
1905. Sabin, Alvah H., 432, Sandford Avenue, Flushing, N.Y., U.S.A., Chemist, Varnish Works.
1883. Sadler, A. E., Sand Hall, Ulverston, Lancashire, Manufacturing Chemist.
- O.M. Sadler, Sir Samuel A., Middlesbrough-on-Tees, Colour Manufacturer.
1908. Sadtler, Philip B., c/o Geo. M. Newhall Engineering Co., Ltd., 136, South 4th Street, Philadelphia, Pa., U.S.A., Engineer.
1884. Sadtler, Dr. S. P., 145, North 10th Street, Philadelphia, Pa., U.S.A., Consulting Chemist.
1896. Sadtler, Dr. S. S., c/o Samuel P. Sadtler and Son, 39, South 10th Street, Philadelphia, Pa., U.S.A., Analytical and Consulting Chemist.
1897. Sage, C. Edward, c/o W. C. Nickels, 41, Cheapside, London, E.C., Consulting Chemist.
1902. Sahm, Louis N., 22, Cliff Street, New York City, U.S.A., Chemist.
1907. Saiki, Kenkichi, Guantanamo Sugar Co., Los Canos, Guantanamo, Cuba, Chemist.
1884. Salamon, A. Gordon, 1, Fenchurch Avenue, London, E.C., Consulting Chemist.
1885. Salamon, Jno., Rainham, S.O., Essex, Manufacturing Chemist.
1884. Salis-Mayenfeld, Dr. E. von, 966, Madison Avenue, Albany, N.Y., U.S.A., Technical Chemist.
1907. Samuel, Marcus R. A., 12, Minorities, London, E.C., Merchant.
- O.M. Samuel, W. Cobden, 66, Croxted Road, West Dulwich, S.E., Analytical Chemist.
1896. Samuelson, Francis A. E., Sir B. Samuelson and Co., Ltd., Middlesbrough, Ironmaster.
1904. Sand, Dr. Henry J. S., University College, Nottingham, Lecturer and Demonstrator.
1909. Sandberg, Sixten, Skutskär Sulphite and Soda-pulp Mills, Skutskär, Sweden, Chemist and Mill Manager.
1906. Sanders, J. McConnell, c/o Dirección General de Aduanas, Palacio Nacional, Mexico, D. F., Analytical Chemist.
1902. Sanders, Warren W., 127, Vernon Street, Gardner, Mass., U.S.A., Chemist.
1895. Sanderson, John, c/o B. S. Cohen, Ltd., 15, Clerkenwell Close, London, E.C., Chemist.
1898. Sanderson, T. Crisp, Dubois Avenue, West New Brighton, N.Y., U.S.A., Chemical Engineer.
1907. Sandig, A., 229, Kinzie Street, Chicago, Ill., U.S.A., Sales Manager.
- O.M. Sanford, P. Gerald, 14, Wellington Road, Croydon, Public Analyst and Consulting Chemist.
1908. Sang, Alfred, c/o Garland Corporation, Pittsburg, Pa., U.S.A., Manufacturer and Consulting Engineer.
1890. Saniter, E. H., Strafford Villa, Moorgate, Rotherham, Analytical Chemist.
1901. Sargent, Dr. Geo. W., c/o The Carpenter Steel Co., Reading, Pa., U.S.A., Chemist and Metallurgist.
1909. Sargent, Ledyard W., Roessler and Hasslacher Chem. Co., Plant No. 2, Perth Amboy, N.J., U.S.A., Chemist.
1903. Saunders, Lewis E., 123, Buffalo Avenue, Niagara Falls, N.Y., U.S.A., Electro-Chemical Engineer.

1896. Saunders, Walter M., 20, Dewey Street, Olneyville, R.I., U.S.A., Analytical Chemist.
1895. Savage, Arthur E., Smelting Works, Port Kembla, N.S.W., Australia, Metallurgist.
1895. Sawers, Wm. D., 3, Hillside Gardens, Partick Hill, Glasgow, Chemist.
1901. Sawyer, Dr. Harris E., Bureau of Chemistry, Washington, D.C., U.S.A., Chemist.
1907. Saxe, Joel B., P.O. Box 554, Montreal, Canada, Chemist.
1898. Saxe, Sigmond, 107, Manhattan Avenue, New York City, U.S.A., Manufacturing Chemist.
1895. Sayer, Harry, 5, Orchard Road, High Barnet, Herts., Metallurgical Chemist.
1890. Sayers, Jos. J., Nobel Villa, Stevenston, Ayrshire, Explosives Chemist.
1895. Scales, F. Shillington, "Jersey," St. Barnabas Road, Cambridge.
1899. Schaak, Dr. Milton J., 108, Penn Street, Brooklyn, N.Y., U.S.A., Chemist.
- O.M. Schack-Sommer, Dr. C., 87, Victoria Street, London, S.W., Sugar Refiner.
1908. Schad, Dr. Philip, Winnington Park, Northwich, Cheshire, Manufacturing Chemist.
1899. Schaefer, Dr. L., Maywood, N.J., U.S.A., Manufacturing Chemist.
1908. Schatzmann, Dr. Paul, Isleben bei Fluelen, Switzerland, Chemist.
1908. Scheele, Edward H., 3, Lloyds Avenue, London, E.C., Chemical Merchant.
1906. Scheffler, Heinrich, c/o Orme & Co., 17-19, Russell Street, London Road, Manchester, Chemical Apparatus Manufacturer.
1903. Scheidel, Dr. Aug., Mutual Life of New York Building, Martin Place, Sydney, N.S.W., Australia, Managing Director.
1886. Schellhaas, Henry Alf., Thornhill, Beach Road, Hartford, Northwich, Mechanical Engineer.
1904. Schenk, Henry, 15, University Place, New York City, U.S.A.
1894. Schidrowitz, Dr. P., 57, Chancery Lane, London, W.C., Research Chemist.
1895. Schieffelin, Dr. W. Jay, 841, Southern Boulevard, New York City, U.S.A., Manufacturing Chemist.
1905. Schill, Dr. Emil, c/o G. Siegle Co., Rosebank, Staten Island, N.Y., U.S.A., Chemist.
1909. Schlagintweit, Theo., 94, Market Street, Manchester, Imperial German Consul.
1902. Schlegel, Jno. Wm., cor. Main and Toledo Avenues, Elmhurst, Long Island, N.Y., U.S.A., Chemist.
1893. Schleicher, Francis J., 38, West Tenth Street, Long Island City, N.Y., U.S.A., Technical Chemist.
1902. Schlesinger, Basil E., Brookline, Mass., U.S.A., Chemist.
1901. Schlichting, Emil, 38, Cranberry Street, Brooklyn, N.Y., U.S.A., Chemist.
1908. Schmatolla, Ernst, 317, High Holborn, London, W.C., Consulting Chemical Engineer.
1905. Schmidt, Herman B., 2523, Essex Place, East Walnut Hill, Cincinnati, Ohio, U.S.A., Manufacturing Chemist.
1906. Schmidt, J., 52, Camberwell Green, London, S.E., Works Manager.
1907. Schmitt, Charles A., The Carter's Ink Co., 172, Columbus Avenue, Boston, Mass., U.S.A., Chemist.
1906. Schneible, Joseph, 122, Monroe Street, Chicago, Ill., U.S.A., Chemical Engineer.
1901. Schneider, Edw. J., c/o Electro-Metallurgical Co., Niagara Falls, N.Y., U.S.A., Chemist.
1899. Schniewind, Dr. F., c/o German American Coke and Gas Co., 17, Battery Place, New York City, U.S.A., President.
1904. Schniewind, Heinrich, Jun., Susquehanna Silk Mills, 18, West 18th Street, New York City, U.S.A., Vice-President and Treasurer.
1907. Schober, Prof. W. B., Lehigh University, South Bethlehem, Pa., U.S.A., Professor of Chemistry.
1897. Schoder, Dr. Robt., 6, Brandreth Road, Balbam, S.W., Chemist.
1904. Schoeller, Dr. Walter R., c/o The Famatina Development Corporation, Chilecito, Prov. Rioja, Argentine Republic, Analytical Chemist.
1902. Schofield, Jas. A., The University, Sydney, N.S.W., Australia, Lecturer in Chemistry.
1908. Scholefield, Fred., c/o Henry Ashwell and Co., Ltd., New Basford, Nottingham, Works Chemist.
- O.M. Scholefield, H. E., Edge Hill Chemical Works, Liverpool, Chemical Manufacturer.
1898. Scholes, Geo. R., Analytical Chemist.
1906. Schramm, Quirin, 20, Avenue Crescent, Leeds, Chemist.
1906. Schroeder, C. M. E., 221, Pearl Street, New York City, and (Journals) Rutherford, N.J., U.S.A., Analytical Chemist.
1895. Schroeder, E. August, c/o Church and Dwight Co., 36, Ash Street, Brooklyn, N.Y., U.S.A., Chemist.
1908. Schüll, Gustav, Messrs. Carl Schleicher & Schüll, Düren, Rheinland, Germany, Filter Paper Manufacturer.
1906. Schulten, Dr. C., P.O. Box 279, Calcutta, India, Analytical Chemist.
1904. Schultz, Carl R., 440, First Avenue, New York City, U.S.A., Mineral Water Manufacturer.
1901. Schultze, Wm., c/o General Chemical Co., Laurel Hill, Long Island, N.Y., U.S.A., Chemist.
1893. Schüpphaus, Dr. R. C., 1466, Dean Street, Brooklyn, N.Y., U.S.A., Consulting Chemist.
1893. Schwab, Dr. L. C., Sedanstrasse 53, Bernburg, Anhalt, Germany, Technical Chemist.
1908. Schwalbe, Dr. Carl G., Rossdorferstrasse 86, III, Darmstadt, Germany, Professor (Technische Hochschule).
1907. Schwann, Chas. W., c/o Antoine Chiris, 20, Platt Street, New York City, U.S.A., Chemist.
1902. Schwarz, Gustav A., Grasselli Chemical Co., 60, Wall Street, New York City, U.S.A., Manager.
1909. Schwarz, Theo., Ashton House, Cliffe at Hoo, Kent, Technical Chemist.
1889. Schweich, Emile. See Mond, Emile S.
1903. Schweickert, Karl, 45, Hazelwood Avenue, Rahway, N.J., U.S.A., Chemist.
1894. Schweitzer, Dr. H., 117, Hudson Street, New York City, U.S.A., Chemical Expert.
1906. Schwerin, Lorenz R., c/o Casein Co. of America, Bainbridge, N.Y., U.S.A., Vice-President, Casein Co.
1906. Scott, Alex. C., Davington House, Faversham, Kent, Assistant Manager (Cotton Powder Co.).
1891. Scott, Andrew, Royal Gunpowder Factory, Waltham Abbey, Essex, Analytical Chemist.
1906. Scott, A. Putnam, c/o Allegheny Steel Co., Breekenridge, Pa., U.S.A., Metallurgist.
1889. Scott, Ernest G., 2, Talbot Court, Gracechurch Street, London, E.C.; and (Journals) 67, Lord Street, Liverpool, Soap Works Chemist.
1898. Scott, Jas., Cawnpore Woollen Mills, Cawnpore, India, Chemist.
1894. Scott, Jno. Gillespie, 33, Sciennes Road, Edinburgh, Analytical Chemist.
1902. Scott, Walter, c/o The Powell Duffryn Steam Coal Co., Ltd., Aberaman, near Aberdare, Chemist.
1907. Scott, Wm. F., Madison, Maine, U.S.A., Manager (Madison Woollen Co.).
1894. Scott-Smith, G. E., 67, Surrey Street, Sheffield, Analytical Chemist.
1889. Seovell, M. A., Lexington, Kentucky, U.S.A., Agricultural Chemist.
1904. Seville, Wilbur L., c/o Parke, Davis & Co., Detroit, Mich., U.S.A., Analytical Chemist.
- O.M. Seudder, F., Mersey and Irwell Joint Committee, 44, Mosley Street, Manchester, Chemist.
1895. Seabrooke, H. Cecil, Black Ash, Grays, Essex, Research Chemist.
1906. Seabury, Richard W., c/o Boonton Rubber Co., Boonton, N.J., U.S.A., Factory Superintendent.
1909. Seager, Dan G., Box 57, Thebes, Ill., U.S.A., Chemist.
1889. Searl, Albert, Montreux, Victoria Road, Sideup, Kent, Technical Chemist.

1898. Searle, Alfred B., Cliftonville, Claremont, Sheffield, Analytical Chemist.
1905. Seaver, Joshua, 7, West Seventh Street, South Boston, Mass., U.S.A., Dealer in Dyestuffs and Chemicals.
1907. Sebold, George, 354, Elizabeth Avenue, Elizabeth, N.J., U.S.A.
1901. Sederholm, Erik, K. Flottans Varf, Stockholm, Sweden, Chemist (Royal Navy Board).
1905. Seebohm, H. C. A., 117, Hudson Street, New York City, U.S.A., Importer of Dyestuffs and Chemicals.
1905. Seeker, A. F., 528, Eighth Street, Brooklyn, N.Y., U.S.A., Food Analyst.
1907. Seelmann, Dr. A., Uhlenhorsterweg 3, Hamburg, Germany, Managing Director of Explosives Works.
1893. Sefton-Jones, Herbert, c/o W. P. Thompson and Co., 322, High Holborn, London, W.C., Chemist.
1902. Segaert, Edw., Colonial Sugar Refining Co., Ltd., O'Connell Street, Sydney, N.S.W., Australia, Analytical Chemist.
1899. Seher, A., c/o Maas and Waldstein Co., Riverside Avenue, Newark, N.J., U.S.A., Chemist.
1907. Seidensticker, Lewis J., c/o Arbuckle Bros. Sugar Refinery, Foot of Pearl Street, Brooklyn, N.Y., U.S.A., Chief Chemist.
1896. Seldner, Rudolph, 1395, Dean Street, Brooklyn, N.Y., U.S.A., Manufacturing Chemist.
1904. Seligman, Dr. Richard, 109, Queen Victoria Street, E.C.; and (Journals) 25, Brunswick Gardens, London, W., Chemist.
1903. Sellen, Elijah, Gasworks Laboratory, Elm Station, Montreal, Canada, Chemist.
1905. Sellers, Geo. E., Rock View, Milnsbridge, near Huddersfield, Aniline Colour Maker.
1898. Sen (Gupta), Nagendra Nath, 19, Lower Chitpur Road, Calcutta, India, Physician and Chemist.
1899. Senior, Francis L., Box 31, Sanford, Maine, U.S.A., Mill Chemist.
1906. Setz, C. F., Hereulaneum, Mo., U.S.A., Chemist and Metallurgist.
1905. Sewell, B. F. Brooke, P.O. Box, 70, Washington, D.C., U.S.A., Chemical Engineer.
1896. Seyler, Clarence A., Public Analyst's Office, Nelson Terrace, Swansea, Chemist and Assayer.
1907. Seymour, Tom G., 26, Karslake Road, Wavertree, Liverpool, Analytical Chemist.
1903. Shacklady, T. G., c/o British Turpentine Corporation, Ltd., Hayes, Middlesex, Technical Chemist.
1906. Shadbolt, Fred., c/o South Metropolitan Gas Co., Chemical Works, East Greenwich, S.E., Chemical Engineer and Manager.
1906. Shah, Prof. S. J., Dhanasutar's Street, Dehra's Pole, Ahmedabad, India, Professor of Science.
1905. Shainwald, R. L., jun., Bound Brook, N.J., U.S.A., and (Journals) Paperhuderstrasse 3, Hamburg, Germany, Chemist.
1906. Shankland, George A., Edge Hill, Mansfield Woodhouse, Notts., Manager.
1892. Shanks, Arch., Bridgend Mills, Dalry, Ayrshire, N.B., Chemist.
1908. Shanks, John, Dalmeny Hook, Barrhead, N.B., Sanitary Engineer.
1883. Sharp, James, Shirley Manor, Wyke, near Bradford, Yorks., Dyer.
1909. Sharp, James B., Thorn Bank, Marple, Cheshire, Chemical Representative (Meister, Lucius, und Brüning).
1903. Sharples, G. H., Holly Villas, Sutton Lane, Middlewich, Cheshire, Works Chemist.
1905. Sharples, Philip P., 22, Concord Avenue, Cambridge, Mass., U.S.A., President (Nat. Coal Tar Co.).
1884. Sharples, Stephen P., 26, Broad Street, Boston, Mass., U.S.A., Analytical Chemist.
1900. Sharwood, Wm. J., c/o Homestake Mining Co., Lead, South Dakota, U.S.A., Metallurgical Chemist.
1900. Shattuck, A. F., c/o Solvay Process Co., Detroit, Mich., U.S.A., Chemist.
1906. Shaw, H. G., Box 373, Barberton, Ohio, U.S.A., Chemist.
1906. Shaw, Ronald W. F., c/o Thacker, Spink and Co., P.O. Box 54, Calcutta, India, Principal.
1908. Shaw, Dr. T. P., 1022, Dorchester West, Montreal, Canada, Doctor of Medicine.
1904. Shedden, Frank, Hurst Road, Hinekley, Leicestershire, Science Master.
1905. Sheldon, John C., 8, Glenbank Terrace, Lenzie, N.B., Chemist.
1903. Sheldon, Dr. N. L., Cordite Factory, Aruvankad, Nilgiri Hills, India, Works Manager.
1892. Shenton, Jas. P., 37, Torbay Road, Chorlton-cum-Hardy, near Manchester, Analytical Chemist.
1889. Shepard, Dr. Chas. U., (communications) P.O. Box 42, Summaerville, S.C.; and (Journals) P.O. Box 284, Charleston, S.C., U.S.A.
1906. Shepard, Jas. H., Experimental Station, Brookings, S. Dak., U.S.A., Agricultural Chemist.
1907. Shephard, Fred. G., 5, University Road, Galway, Ireland, Chemist.
1904. Shepherd, A. B., Copenhagen Oil Mills, Limehouse, London, E., Analytical Chemist.
1900. Shepherd, E. Sanger, 68, Adelaide Road, London, N.W., Scientific Instrument Maker.
1893. Shepherd, H. H. B., Northcote, Mount Pleasant Lane, Upper Clapton, N.E., Chemist.
1898. Shepherd, Reginald des F., Central Laboratory, Rhodes, Manchester, Printworks Chemist.
1909. Shepherd, Stephen W., Bradford Corporation Chemical Works, Frizinghall, Bradford, Yorks., Works Manager.
1899. Shero, John E., c/o Aluminium Co. of America, Niagara Falls, N.Y., U.S.A., Chemist.
1906. Sherwin, R. S., c/o Aluminium Co. of America, East St. Louis, Ill., U.S.A., Chemist.
1893. Shields, Dr. John, Minas de Rio Tinto, Prov. de Huelva, Spain, Chemist.
1907. Shilstone, Herbert M., c/o Penick and Ford, Ltd., 416, South Front Street, New Orleans, La., U.S.A., Analytical Chemist.
1896. Shimomura, K., Shinkarasumaru Kojinguchi Sagaru, Kyoto, Japan, Professor of Chemistry.
1886. Shimose, Masachika, 110, Hakusan-totenmachi, Koishikawa, Tokyo, Japan, Chemical Engineer.
1888. Shishkoff, Sergius A., Perm, Russia, Glass Manufacturer.
1905. Shoffstall, Arthur S., c/o Orford Copper Co., New Brighton, S.I., N.Y., U.S.A., Chemist.
1899. Sholes, Chas. E., 164, Front Street, New York City, U.S.A., Chemical Agent.
1900. Shonk, Albert, 87, Dartmouth Road, Hendon, N., Analytical Chemist.
1897. Shores, Dr. Jeff. H., King's Road, Wallsend-on-Tyne, Chemist.
1904. Short, Andrew, Choppington, Morpeth, Works Chemist.
1902. Shoubridge, Sydney Y., M.I.C.E., Gasworks, Lower Sydenham, S.E., Gas Engineer.
1907. Shuey, Philip McG., 423, Bull Street, Savannah, Ga., U.S.A., Analytical Chemist.
1901. Shukoff, Dr. Alexis A., Borowaja No. 86, St. Petersburg, Russia, Technical Chemist.
1899. Shuler, Darius P., Sudbury, Ont., Canada, Chemist.
1890. Shutt, Frank T., Central Experimental Farm, Ottawa, Canada, Agricultural Chemist.
1906. Shuttleworth, E. B., 220, Sherbourne Street, Toronto, Canada, Chemist.
1901. Siau, Raymond L., Springfield Brewery, Wolverhampton, Research Chemist.
1902. Sibley, Samuel E., 13, Cook Road, Centennial Park, Sydney, N.S.W., Australia, Technical Chemist.
1907. Siebel, Fred. P., 1122, Montana Street, Chicago, Ill., U.S.A., Analytical Chemist.
1902. Siebold, Alfred, c/o British Dyewood and Chemical Co., Lacovia P.O., Jamaica, Technical Chemist.
1901. Silberrad, Dr. Oswald, Sunny Croft, Buckhurst Hill, Essex, Research Chemist.
1892. Silvester, Harry, 78, Holyhead Road, Handsworth, Birmingham, Analytical and Consulting Chemist.

1901. Sim, Wilfrid A., c/o Wm. Sim and Sons, 40, Jane Street, Leith, N.B., Colour Manufacturer.
1903. Simmons, Wm. H., Oakleigh, Stoke Newington Common, N., Analytical Chemist.
1898. Simon, Dr. A., 55-56, Bishopsgate Street, London, E.C., Chemical Engineer.
1890. Simonds, Dr. F. M., 60, Wall Street, New York City, U.S.A., Mining Engineer and Assayer.
1905. Simons, Albert J., Pontianak, Dutch West Borneo, vii Singapore, S.S., Engineer.
1906. Simons, F. D., Continental Mexican Rubber Co., Apartado 176, Torreon, Mexico, Chemist.
1902. Simonsen, Wm., 126, West 9th Street, Cincinnati, Ohio, U.S.A., Chemist.
1905. Simpson, Henry, 34, Kimbolton Avenue, Lenton Sands, Nottingham, Works Chemical Assistant.
- O.M. Simpson, W. S., The Gables, Cannon Hill, Southgate, N., Analytical Chemist.
1900. Sims, W. Edgar, c/o British Aluminium Co., Ltd., Larne Harbour, Co. Antrim, Ireland, Assistant Manager.
1894. Sinclair, Dr. W., 60, Stirling Road, Trinity, Edinburgh, Chemist.
1890. Sindall, R. W., 201, Wellmeadow Road, Catford, S.E., and (Journals) Oxford Court, Cannon Street, E.C., Paper Chemist.
1889. Singer, Ignatius, 3, Parkfield Road, Manningham, Bradford, Manufacturing Chemist.
1899. Singmaster, J. Arthur, c/o New Jersey Zinc Co. of Penna., Palmerton, Pa., U.S.A., Chemist.
1901. Sinnatt, Frank S., Glenside, Church Lane, Moston, Manchester, Demonstrator of Chemistry.
- O.M. Sisson, G., jun., 13, Grey Street, Newcastle-on-Tyne, Technical Chemist.
1905. Sjöström, Waldemar L., 37, Farnham Street, Lawrence, Mass., U.S.A., Dyeworks Superintendent.
1885. Skaife, Wilfred T., 70, Sherbrooke Street West, Montreal, Canada, Sugar Chemist.
1894. Skelton, John R., c/o Norwich Crape Co., Ltd., St. Augustine's, Norwich, Managing Director.
1897. Skertchly, W. P., Laboratory, 11, Billiter Square, London, E.C., Analytical Chemist.
1891. Skilton, C. F. E., c/o Beamish and Crawford, Ltd., Cork, Ireland, Brewer.
1901. Skinner, Hervey J., c/o A. D. Little, 93, Broad Street, Boston, Mass., U.S.A., Chemist.
1908. Skinner, Wm., 38, Sauchiehall Street, Glasgow, Analytical Chemist.
1904. Skirrow, Dr. F. W., 17, Curzon Avenue, Victoria Park, Manchester, Research Chemist.
1904. Skowronski, S., c/o Amer. Smelting & Refining Co., Manrer, N.J., U.S.A., Chemist.
1891. Skurray, Thos., The Brewery, 40, Oak Street, Abingdon, Berks, Brewer.
1904. Slater, Dr. Arthur, The Priory, Burton-on-Trent, Lecturer and Demonstrator.
1887. Slatter, Geo. W., 241, Carlton Terrace, Nab Wood, Shipley, Yorkshire, Analytical Chemist.
1906. Sleeper, Robt. R., 112, Charles Street, Lowell, Mass., U.S.A., Instructor in Dyeing.
1895. Slocum, Dr. Frank L., 401, South Linden Avenue, E.E., Pittsburg, Pa., U.S.A., Chemist.
1883. Smail, J. L., Warren Wood, Hayes Common, Beckenham, Kent, Chemical Manufacturer.
1908. Small, Bertram G., Beechlands, Timperley, Cheshire, Managing Engineer.
1898. Small, Fritz H., c/o Graton and Knight Manufacturing Co., Worcester, Mass., U.S.A., Chemist.
1904. Smallman, J. E., c/o Canada Chemical Manufacturing Co., Ltd., London, Ont., Canada, Chemist.
1904. Smart, Bertram J., Chem. Research Laboratory, Royal Arsenal, Woolwich, S.E., Chemist.
1906. Smart, Leslie A., 720, McIntyre Building, Winnipeg, Man., Canada, City Analyst.
- O.M. Smetham, A., 16, Brunswick Street, Liverpool, Analytical Chemist.
1904. Smith, Albert E., c/o Mount Hope Finishing Co., North Dighton, Mass., U.S.A., Superintendent.
1905. Smith, Prof. Albert W., Case Library, Cleveland, Ohio, U.S.A., Prof. of Chemistry.
1898. Smith, Alf. B., Ryecroft, Glossop, Derbyshire, Bleacher and Dyers' Manager.
1897. Smith, Allan, c/o Kellner-Partington Paper Pulp Co., Hallein, bei Salzburg, Austria, Chemist.
1896. Smith, Andrew T., c/o Castner-Kellner Alkali Co., Ltd., 43, Castle Street, Liverpool, General Manager.
1905. Smith, Arthur, Town End Chemical Works, Bramley, Leeds, Chemical Manufacturer.
1906. Smith, Arthur D., c/o Canfield Oil Co., Coraopolis, Pa., U.S.A., Superintendent.
1893. Smith, Edgar B., Box 599, Sydney, Nova Scotia, Canada, Chemist.
1906. Smith, E. A. Cappellet, c/o Baltimore Copper Smelting and Rolling Co., P. O. Station J., Baltimore, Md., U.S.A., Metallurgical Engineer.
1895. Smith, Dr. E. Ellsworth, 26, East 29th Street, New York City, U.S.A., Consulting Physiological Chemist.
1892. Smith, Ernest A., The Assay Office, Leopold Street, Sheffield, Assayer.
1903. Smith, Ewing, c/o Borneo Co., Ltd., Kuching, Sarawak, Borneo, Analytical Chemist.
1903. Smith, F. M., 100, William Street, New York City, U.S.A., President (Pacific Coast Borax Co.).
1891. Smith, Francis P., 24-26, East 21st Street, New York City, U.S.A., Chemist.
1907. Smith, Frank Morse, 100, William Street, New York City, U.S.A., Chemical Merchant.
- O.M. Smith, G., Roschall Terrace, Falkirk, N.B., Explosive Works Manager.
1908. Smith, George A., 1069, Prospect Place, Brooklyn, N.Y., U.S.A., Chemist (Printing Ink Manufacturing).
1907. Smith, George D., 216, Milk Street, Boston, Mass., U.S.A., Salesman.
1897. Smith, Sir Geo. J., c/o Bickford, Smith, and Co., Ltd., Tuckingmill, Cornwall, Fuse Manufacturer.
1906. Smith, Geo. Thos., 94, Leadenhall Street, London, E.C., Chemical and Colour Merchant.
1890. Smith, Harry, Tower House, Freshfield, near Liverpool, Cons. Chemist (Paints and Pigments).
1890. Smith, Harry E., 80, Knowles Street, East Cleveland, Ohio, U.S.A., Analytical Chemist.
1904. Smith, Henry, 83, Brownlow Road, Horwich, Bolton-le-Moors, Lancs., Analytical Chemist.
1902. Smith, Hy. Geo., Technological Museum, Harris Street, Ultimo, Sydney, N.S.W., Australia, Assistant Curator and Chemist.
1905. Smith, H. Melville, Ammunition Works, Abbey Wood, Kent, Engineer and Superintendent.
1901. Smith, H. Procter, Shotton Lane, Shotton, Flintshire, Metallurgical Chemist.
- O.M. Smith, H. R., 1, Aubert Park, Highbury, London, N., Analytical Chemist.
1890. Smith, H. Wood, c/o John Batt and Co., Ltd., 39, Old Broad Street, London, E.C., Chemist.
1905. Smith, Hugh Dunford, 8 and 10, The Side, Newcastle-on-Tyne, Analytical Chemist.
1906. Smith, Irwin J., P.O. Box 506, Troy, N.Y., U.S.A., Salesman.
- O.M. Smith, Jas., Ash Grove House, Radcliffe, Manchester.
1897. Smith, James, 80, Amphil Road, Aigburth, Liverpool, Analytical Chemist.
1903. Smith, James, Metallurgist.
1907. Smith, Jas. C., c/o Edward Ripley and Son, Ltd., Bowling Dyeworks, Bradford, Dyer.
1893. Smith, Jas. F., 131, Seamer Road, Scarborough, Yorks, Analytical Chemist.
1901. Smith, J. Cruickshank, Holmdene, Colebrooke Avenue, West Ealing, W., Technical Chemist.
- O.M. Smith, Dr. J. H., 60, Rue de la Côte St. Thibault, Bois Colombes, Seine, France, Chemist.
1888. Smith, J. Tertius, Richmond House, Plaistow, Essex, Technical Chemist.
- O.M. Smith, Jno. W., 7, Brookfield Street, Roslindale, Boston, Mass., U.S.A., Analytical Chemist.
1890. Smith, J. Wm., Solvay Process Co., Syracuse, N.Y., U.S.A., Alkali Works Manager.

1896. Smith, Joseph Kent, 1144, Portland Street, Pittsburg, Pa., U.S.A., Chemist, American Vanadium Co.
1898. Smith, R. F. Wood, 9, Lower Thames Street, London, E.C., Consulting Chemist.
1890. Smith, Dr. R. Greig, Linnean Society's House, Elizabeth Bay, Sydney, N.S.W., Entomologist and Chemist.
1890. Smith, R. W., c/o New Transvaal Chemical Co., Delmore, Transvaal, S. Africa, Chemical Works Manager.
1897. Smith, Theophilus R., c/o Brotherton and Co., Ltd., The Wear Tar Works, South Dock, Sunderland, Chemist.
1907. Smith, Thorm, P.O. Box 106, Isabella, Tenn., U.S.A., Chemist (Ducktown Sulphur, &c., Co.).
1896. Smith, Walter E., 141, Cypress Street, Providence, R.I., U.S.A., Instructor in Chemistry.
1903. Smith, Dr. Warren R., Lewis Institute, Chicago, Ill., U.S.A., Teacher.
- O.M. Smith, Watson, 34, Upper Park Road, Haverstock Hill, N.W., Editor of Society's Journal.
1908. Smith, Dr. Watson, jun., De Feers Explosives Works, Somerset West, C.C., South Africa, Chemist.
- O.M. Smith, Wilfred, 182, West Street, Glasgow, Chemical Manufacturer.
1896. Smith, Dr. W. Stanley, Hollies House, Marchweil, near Wrexham, North Wales, Brewer.
- O.M. Smithells, Prof. A., F.R.S., The University, Leeds, Professor of Chemistry.
- O.M. Smithers, F. O., Dashwood House, 9, New Broad Street, London, E.C., Chemical Agent.
1902. Smoot, Albert M., 99, John Street, New York City, U.S.A., Analytical Chemist.
1902. Smythe, Dr. Jno. A., Armstrong College, Newcastle-on-Tyne, Demonstrator in Chemistry.
1902. Smythe, Dr. J. S., Rantallard, Lance Lane, Wavertree, Liverpool, Analytical Chemist.
1888. Snape, Dr. H. Lloyd, Balholm, Lathom Road, Southport, Director of Education for Lancashire.
1908. Snell, John F., Macdonald College P.O., Prov. Quebec, Canada, Assistant Professor of Chemistry.
1896. Snowdon, J., jun., Messrs. Snowdon, Sons & Co., Millwall, E., Chemical and Oil Manufacturer.
1900. Sodeau, Dr. Wm. H., 19, East Parade, Newcastle-on-Tyne, and (Journals) Torpedofabrik, Fiume, Hungary, Chemist.
1903. Sohlman, Ragnar, Bofors, Sweden, Manager (A. B. Bofors' Nobelkrut).
1894. Sohn, Chas. E., 52, Fore Street, London, E.C., and (Journals) 82, Wightman Road, Harringay, N., Analyst.
1906. Solomon, M., 45, Newhall Street, Birmingham, Manager (Carbon Works).
1895. Solvay, Armand, 25, Rue Prince Albert, Brussels, Cérant de la Société Solvay et Cie.
1884. Solvay, Ernest, 43, Rue des Champs Elysées, Brussels, Alkali Manufacturer.
1897. Somerset, H. St. John, jun., Mount Morgan Gold Mining Co., Mount Morgan, Queensland, Australia, Assayer.
1884. Sommer, Adolf, corner 1st and Binney Streets, East Cambridge, Boston, Mass., U.S.A., Pharmaceutical Chemist.
1909. Sommer, Dr. Albert, 17, Battery Place, New York City, U.S.A., Engineer Chemist (The Texas Co.).
1904. Southall, A. W., Lower Priory, Birmingham, Manufacturing Chemist.
1908. Southcombe, James E., Imperial Oil Works, Salford, Lancashire, Chemist.
1896. Souther, H., 440, Capitol Avenue, Hartford, Conn., U.S.A., Chemical and Metallurgical Engineer.
1904. Southenden, F., 11, Gordon Road, Exeter, Teacher of Chemistry.
1892. Southern, Thos., Wheathill Chemical Works, St. Simon Street, Salford, Manufacturing Chemist.
1883. Soward, A. W., 28, Therapia Road, Honor Oak, S.E., Principal Clerk (Legacy Duty Office).
1908. Sowden, Parkin T., c/o Standard Silver Co., 35, Hayter Street, Toronto, Canada, Mechanical Engineer.
1890. Sowerby, Thos. H., Canal Soap Works, Verney Road, Rotherhithe, S.E., Soap Manufacturer.
- O.M. Sowerby, W. M., c/o United Alkali Co., Ltd., All-husen Works, Gateshead-on-Tyne, Manager.
1887. Spackman, Chas., Roschaugh, Clitheroe, Lancashire, Portland Cement Manufacturer.
1904. Sparre, Fin, 606, West 20th Street, Wilmington, Del., U.S.A., Chemist.
1904. Speiden, C. C., 46, Cliff Street, New York City, U.S.A., Chemical Merchant.
1905. Speight, W. E., Sewage Works, Deighton, Huddersfield, Chemist.
1883. Spence, D., Manchester Alum Works, Manchester, Alum Manufacturer.
1900. Spence, Howard, (Journals) Audley, Broad Road, Sale, Cheshire; and Alum Works, Manchester, Chemical Manufacturer.
1909. Spence, Jno., 113, West Regent Street, Glasgow, Analyst.
1883. Spence, Jno. W., Tiviot Colour Works, Manchester Road, Stockport, Drysalter.
1903. Spencer, A. Gordon, Central Experimental Farm, Ottawa, Canada, Chemist.
1906. Spencer, Fred. W., c/o Ammonia Co. of Australia, Clyde, and (Journals) Cheltenham, Redmyre Road, Strathfield, Sydney, N.S.W., Australia, Works Manager.
1909. Spencer, George, c/o The Gorton Rubber Co., Ltd., Openshaw, Manchester, Managing Director.
1884. Spencer, Jno., Globe Tube Works, Wednesbury, Tube Manufacturer.
1902. Sperry, Elmer A., 100, Marlborough Road, Prospect Park South, Brooklyn, N.Y., U.S.A., Electrical Engineer.
1897. Sperry, Erwin S., "The Brass World," 260, John Street, Bridgeport, Conn., U.S.A., Metallurgist and Editor.
1906. Spicer, J. Spofford, 2043, North Second Street, Harrisburg, Pa., U.S.A., Chemist (Penna. Dept. of Agriculture).
1884. Spiegel, Dr. Adolf, Messel, bei Darmstadt, Germany, Analytical Chemist.
1903. Spielmann, Dr. P. E., 21, Cadogan Gardens, London, S.W., Chemical Student.
1906. Spiera, Dr. V. G., 37, Thornton Avenue, Streatham Hill, S.W., Chemist.
1889. Spies, Adolph, 102, Fenchurch Street, London, E.C., Chemical Merchant.
1889. Spies, Hermann, 102, Fenchurch Street, London, E.C., Chemical Merchant.
1885. Spiller, A., Edison-Swan Electric Co., South Benwell Works, Newcastle-on-Tyne, Electrician.
- O.M. Spiller, J., 2, St. Mary's Road, Canonbury, London, N., Consulting Chemist.
1896. Spoor, J. L., Rede Court, Rochester, Kent, Portland Cement Manufacturer.
1900. Spurge, Edw. C., University Chib, Niagara Falls, N.Y., U.S.A., Chemist.
- O.M. Squire, P. W., 413, Oxford Street, London, W., Pharmaceutical Chemist.
1896. Stafford, Chas. H., c/o The Birkacre Printing Co., Chorley, Lancs., Colourist.
- O.M. Stahl, Dr. K. F., 57th Street and A. V. Ry., Pittsburg, Pa., U.S.A., Chemical Works Manager.
1905. Stahl, Dr. Paul G., 13, Square de Jussieu, Lille (Nord), France, Chemical Manufacturer.
1904. Standfast, Jno. T., c/o Messrs. Burt, Boulton, and Haywood, Ltd., Prince Regent's Wharf, Silvertown, E., Chemist.
1906. Stanley, Wm., Great Barrington, Mass., U.S.A., Engineer.
1888. Stantial, Frank G., c/o Cochrane Chemical Co., Everett, Mass., U.S.A., Technical Chemist.
1885. Staples, H. J., The Old Hall, Spondon, Derby, Colour Manufacturer.
- O.M. Stark, J. F., Rosedale, Bromborough, Cheshire, Works Manager.
1896. Statham, Noel, c/o The West Virginia Paper and Pulp Co., Mechanieville, N.Y., U.S.A., Engineer.
1908. Statiropoulos, Dr. John G., Anatolia College, Marsovan, Turkey-in-Asia, Chemist.

1907. Staud, Joseph E., c/o W. W. Laurence & Co., Pittsburgh, Pa., U.S.A., Chemist.
1904. Stauffacher, W., 64, Oberwilerstrasse, Basle, Switzerland, Chemical Works Manager.
1908. Stayer, Charles A., 8, East Center Street, South Manchester, Conn., U.S.A., Silk Colour Mixer.
1895. Stead, J. Christopher, Llanfynydd, Wrexham, North Wales, Technical Chemist.
- O.M. Stead, J. E., F.R.S., 11, Queen's Terrace, Middlesbrough-on-Tees, Analytical Chemist.
- O.M. Stebbins, Dr. J. H., 3, East 29th Street, New York City, U.S.A., Analytical Chemist.
- O.M. Steedman, R. H., Whitfield, Prestwick, Ayrshire, N.B., Chemical Manufacturer.
1896. Steel, Fred. W., c/o Cumming, Smith and Co., Yarraville, Melbourne, Vic., Australia, Chemist.
1900. Steel, Jno. S., Achernat, Blackburn, Melbourne, Vic., Australia, Chemist.
1884. Steel, R. Elliott, Cameron House, Sherborne, Dorset, Headmaster.
- O.M. Steel, Thos., Colonial Sugar Refinery, O'Connell Street, Sydney, N.S.W., Australia, Sugar Chemist.
1906. Steers, Thornton, 224, Grand Avenue, Brooklyn, N.Y., U.S.A., Chemist.
1905. Steiger, George, c/o U.S. Geological Survey, Washington, D.C., U.S.A., Chemist.
1897. Stein, Sigmund, 214, Upper Parliament Street, Liverpool, Sugar Refinery Manager.
1897. Steinhart, Dr. Oscar J., 2 and 3, West Street, Finsbury Circus, London, E.C., Manufacturing Chemist.
1903. Stell, S. F., 25, Henry Street, Keighley, Yorks., Teacher of Chemistry.
1887. Stenhouse, T., 166, Drake Street, Rochdale, Analytical Chemist.
1908. Stenhouse, Thos., jun., Chemical Laboratory, H.M. Dockyard, Portsmouth, Analytical Chemist.
1904. Stephen, A. E., 33, Victoria Street, Ashfield, Sydney, N.S.W., Australia, Analytical Chemist.
1884. Stephens, H. Chas., M.P., Avenue House, Finchley, N., Ink Manufacturer.
1892. Stephens, M. E., 4, Carlton Gardens, London, S.W.; and (Journals) 57-60, Aldersgate Street, London, E.C., Ink Manufacturer.
1889. Stern, Arthur L., 148, High Street, Burton-on-Trent, Brewing Chemist.
1906. Sternberg, Frank J. N., 155, Dunn Avenue, Toronto, Canada, Analytical Chemist.
- O.M. Stuart, D. R., Osborne Cottage, Broxburn, West Lothian, N.B., Oilworks Chemist.
1903. Steven, A. B., The Technical College, Glasgow, Lecturer on Dyeing.
1907. Steven, Michael M., c/o The Distillers' Co., Ltd., 12, Torphichen Street, Edinburgh, Analytical Chemist.
1899. Stevenot, G. A., c/o H. A. Metz Co., 210, South Tryon Street, Charlotte, N.C., U.S.A., Chemist.
1898. Stevens, Arthur F., 96, Newgate Street, London, E.C., Paper Examiner.
1902. Stevens, Dr. Hy. P., Laboratory, 15, Borough, London Bridge, S.E., Consulting Chemist.
1894. Stevens, Jno. H., 295, Ferry Street, Newark, N.J., U.S.A., Manufacturing Chemist.
1908. Stevens, J. Venn, 34, Linthorpe Road, Stamford Hill, London, N., Analytical Chemist.
1902. Stevens, M. White, H.M. Patent Office, Chancery Lane, London, W.C., Chemist.
1903. Stevens, T. R. B., P.O. Box 57, Kalgoorlie, West Australia, Metallurgical Chemist.
1884. Stevens, Wm., The Native Guano Co., Ltd., 29, New Bridge Street, London, E.C., Secretary.
1907. Stevenson, Chas. E., 80, Polwarth Terrace, Edinburgh, Dyer.
- O.M. Stevenson, W., Standard Works, 95A, Southwark Street, London, S.E., Chemical Manufacturer.
1901. Stewart, David B. D., Aberdeen Comb Works, Hutchison Street, Aberdeen, Managing Director.
1903. Stewart, Jas., "The Gas World," 8, Bouverie Street, Fleet Street, London, E.C., Editor.
1909. Stewart, Jeffrey, India Refining Co., McKean and Swanton Streets, Philadelphia, Pa., U.S.A., Works Manager.
1890. Stewart, Robt., St. Ann's, Luton, Chemical Works Manager.
- O.M. Stewart, S., c/o Michael Nairn and Co., Ltd., Kirkcaldy, Fife, Technical Chemist.
1906. Stickland, Oliver W., c/o The New Explosives Co., Ltd., Stowmarket, Suffolk, Works Chemist.
1904. Stieglitz, Dr. Julius, University of Chicago, Chicago, Ill., U.S.A., Associate Professor of Chemistry.
1904. Stiff, John T., 60, Parrock Street, Gravesend, Kent, Works Chemist.
1908. Stillman, Dr. Thos. B., Stevens Institute of Technology, Hoboken, N.J., U.S.A., Professor of Engineering Chemistry.
1903. Stillwell, Albert G., 164, Front Street, New York City, U.S.A., Chemist.
1903. Stingelin, Dr. Fritz, 78, Oberwilerstrasse, Basle, Switzerland, Chemist.
1886. Stirk, Jos., The Sunnyside Hydro, Southport, Brewer's Engineer.
1893. Stock, F. W., Keating, County Analyst's Office, Darlington, Analytical and Consulting Chemist.
1900. Stockdale, Edgar, c/o R. Dewhurst and Co., Ltd., Printworks, Batley, Yorks, Colour Mixer.
1888. Stockdale, Wm., Rosebank Printworks, Rainsbottom, near Manchester, Calico Printer.
1887. Stocks, H. B., 12, Victoria Road, West Kirby, Cheshire, Analytical Chemist.
1903. Stoddard, Jesse D., Detroit Testing Laboratory, 1111, Union Trust Building, Detroit, Mich., U.S.A.
1885. Stoddart, F. Wallis, Grafton Lodge, Sneyd Park, Bristol, Analytical Chemist.
- O.M. Stoker, G. N., 9, Lessar Avenue, Clapham Common, S.W., Analytical Chemist.
1899. Stokes, Alf. W., Laboratory, Town Hall, Paddington Green, W., Public Analyst.
1898. Stokes, Dr. Henry N., Bureau of Standards, Washington, D.C., U.S.A., Chemist.
1900. Stone, Geo. C., c/o New Jersey Zinc Co., 71, Broadway, New York City, U.S.A., Engineer.
1899. Stone, I. F., 100, William Street, New York City, U.S.A., Chemical Merchant.
1888. Stone, Thos. W., Chemical Works, St. George, Bristol, Chemical Manufacturer.
- O.M. Storey, I. H., Haverbreaks, Lancaster, Chemical Manufacturer.
1903. Stormer, Edward J., c/o J. I. Case Threshing Machine Co., Racine, Wis., U.S.A., Analytical Chemist.
1902. Storr, Bertram V., 147, Coventry Road, Ilford, Essex, Chemist.
1888. Stowe, W. T., Government Laboratory, 280, George Street, Glasgow.
1904. Strange, Edward Halford, 7, Staple Inn, Holborn, London, Technical Research Chemist.
1883. Strangman, J. Pim, 9, Clydesdale Road, Notting Hill, W., Bleacher.
1908. Stratford, Alfred W., 37, Cleveland Road, Crumpsall, Manchester, Chemist.
1903. Strayer, D. W., 428, West King Street, York, Pa., U.S.A., Chemist.
1903. Strickler, Emerson H., c/o General Chemical Co., 25, Broad Street, New York City, U.S.A., Chemist.
1905. Strunz, Dr. C. E., 100, Michigan Street, Pueblo, Colo., U.S.A., Chemist.
1906. Strunz, F. B., Chemical Engineer.
- O.M. Stuart, C. E., 29, Moseley Street, Newcastle-on-Tyne, Chemical Apparatus Dealer.
1905. Stuart, H. E., 176, Purchase Street, Boston, Mass., U.S.A., Vice-President, Mercantile Corporation.
1896. Stuart, Harry T. R., Know Mill House, Entwistle, near Bolton, Printworks Manager.
- O.M. Stuart, T. W., 7, Livingston Drive, Sefton Park, Liverpool, Alkali Works Manager.
1901. Stuart, Dr. W. Theophilus, 197, Spadina Avenue, Toronto, Canada, Professor of Chemistry.
1896. Stubbs, Augustus J., Claris 73, Barcelona, Spain.
- O.M. Studer, Dr. A., Postgebäude, Olten, Switzerland, Consulting Chemist.
1800. Studer, Jos. S., Helvetia, Stockton Heath, near Warrington, Technical Chemist.

1993. Sturrock, Capt. G. C., R.A., Aruvankad, Nilgiris, India, Assistant Superintendent.
1908. Suart, Arthur B., c/o Johnson and Sons' Smelting Works, Paul Street, Finsbury, London, E.C., Bullion Refiner.
1896. Suckert, Dr. J. J., 30, Church Street, New York City, U.S.A., Manufacturing Chemist.
1895. Sudborough, Dr. J. J., University College of Wales, Aberystwith, Lecturer in Chemistry.
1889. Sulman, H. L., 44, London Wall, London, E.C., Chemist and Metallurgist.
1895. Summers, Bertrand S., c/o The Summers Fibre Co., Port Huron, Mich., U.S.A., Electro-Chemist.
1907. Sundarram, Minakshi, c/o Parry & Co., Rampettai, N. Arcot, Madras, India, Agricultural Chemist.
1896. Sunderland, A., 84, Hainworth Wood Road, Ingrow, Keighley, Teacher of Chemistry.
1899. Sundström, Carl, c/o Solvay Process Co., Detroit, Mich., U.S.A., Chemist.
1895. Sundström, Karl J., 355, West Grand Boulevard, Detroit, Mich., U.S.A., Manufacturing Chemist.
1906. Sutermeister, Edwin, c/o Forest Service, Washington, D.C., U.S.A., Chemist.
1881. Sutherland, D. A., 13, Victoria Street, and (Journals) 26, Victoria Street, Westminster, S.W., Consulting Technical Chemist and Assayer.
1909. Sutherland, Daniel M., Ashgrove, Sunbury Common, Middlesex, Works Manager.
1894. Sutherland, Geo., Croft Cottage, Bonhill, N.B., Chemist.
1887. Sutherland, Jas., c/o British Aluminium Co., Ltd., Larne Harbour, Co. Antrim, Ireland, Chemist.
1906. Sutherland, John, The British Aluminium Co., Ltd., Baker Street, Greenock, N.B., Manager of Carbon Factory.
- O.M. Sutherland, R. M., Lime Wharf Chemical Works, Falkirk; and Solgirth, Dollar, N.B., Chemical Manufacturer.
- O.M. Sutton, Dr. Francis, Norfolk County Laboratory, Redwell Street, Norwich, Analytical Chemist.
1886. Sutton, F. Napier, 6, Grosvenor Gardens, Cricklewood, N.W., Alkali Works Inspector.
1900. Sutton, W. Lincoln, Hillcroft, Eaton, Norwich, Public Analyst.
- O.M. Swan, Sir Jos. W., F.R.S., Overhill, Warlingham, Surrey, Chemist and Electrician.
1906. Sweet, Everett F., 52, Union Street, Boston, Mass., U.S.A., Importer.
1905. Swenarton, W. Hastings, Broadway Chambers, 277, Broadway, New York City, U.S.A., Patent Lawyer.
1884. Swinburne, Geo., (Journals) 99, Queen Street, Melbourne, Australia; (subs.) c/o Jno. Coates and Co., Suffolk House, Laurence Pountney Hill, E.C., Gas Engineer.
1904. Swindells, Seth, 181, Orford Lane, Warrington, Chemist.
1901. Swinton, Ralph S., c/o W. J. Bush, Incorporated, Linden, N.J., U.S.A., Analytical Chemist.
1903. Sykes, Walter F., 85, Water Street, New York City, U.S.A., Chemical Merchant.
1902. Sylow, Paul L. P. G., Korsör, Alexandra Street, Drummoyne, Sydney, N.S.W., Australia, Analytical Chemist.
- O.M. Syme, W. B., Elm Cottage, Addiewell, West Calder, N.B., Oil Works Chemist.
1906. Symes, Langford P., Parcora Freezing Works, Timaru, New Zealand, Chemist.
1903. Symmes, Whitman, 1017-1022, Balboa Building, San Francisco, Cal., U.S.A., Chemical Engineer.
1906. Symonds, Abram E., Wick Lane Colour Works, Old Ford Road, Bow, E., Colour Manufacturer.
1909. Tait, Walter Scott, 9, Ellery Street, Cambridge, Mass., U.S.A., Works Manager.
1896. Takagi, T., 10, Nishikatamachi, Hongo, Tokyo, Japan, Chemical Engineer.
- O.M. Takamatsu, T., 13, Nishikatamachi, Hongo, Tokyo, Japan, Analytical Chemist.
- O.M. Takanine, Dr. Jokichi, 550, West 173rd Street, New York City, U.S.A., Engineer.
1890. Takayama, Jintaro, Nando Machi 26, Ushigome, Tokyo, Japan, Director (Imperial Industrial Experiment Station).
1905. Tallot, Prof. Henry P., Mass. Institute of Technology, Boston, Mass., U.S.A., Professor of Inorganic Chemistry.
1898. Tanaka, Keishin, Matsuba Hotel, Kudansaka, Uye, Tokyo, Japan, Chemist.
1900. Tankard, Arnold R., City Analyst's Office, 40, Lowgate, Hull, and (Journals) 12, Feren's Avenue, Cottingham Road, Hull, Analytical Chemist.
1907. Tartar, Herman V., Corvallis, Oregon, U.S.A., Analytical Chemist.
- O.M. Tate, F. H., 9, Hackins Hey, Liverpool, Analytical and Technical Chemist.
- O.M. Tatlock, J., 45, Renfrew Street, Glasgow, Laboratory Furnisher.
- O.M. Tatlock, R. R., 11, Bellshaugh Road, Kelvin-side West, Glasgow, Consulting Chemist.
1902. Tatters, Hugh Lee, 10, Birchfield Road, Widnes, Analytical Chemist.
1906. Tattersfield, Frederick, The Hollins, Dewsbury, Works, Analyst.
1907. Taussig, Dr. Rudolf, 11, Alersstrasse, Vienna VIII., Austria, Chemist.
1905. Tavean, René de Mortemer, U.S. Hygienic Laboratory, 25th and East Streets, N.W., Washington, D.C., U.S.A., Chemist.
1901. Tayler, Jno. Bernard, Anglo-Chinese College, Tientsin, North China, Chemist.
1903. Taylor, Alvin M., c/o General Chemical Co., Station F., Box 12, Cleveland, Ohio, U.S.A., Chemist.
1902. Taylor, Arthur P., c/o John Taylor and Co., 531, Front Street East, Toronto, Ont., Canada, Soap Manufacturer.
1907. Taylor, C. Marshall, International Creosoting and Construction Co., Texarkana, Texas, U.S.A., Chief Chemist.
1902. Taylor, Edward R., Penn Yan, N.Y., U.S.A., Manufacturing Chemist.
1886. Taylor, G. Crosland, Ravenscar, Helsby, near Warrington, Electrical Engineer.
1894. Taylor, G. Midgley, Caxton House, Westminster, S.W., Analytical Chemist.
1893. Taylor, G. W., Dinting Vale Printworks, Dinting, near Manchester, Printworks Chemist.
- O.M. Taylor, H. E., 1, Alexandra Park Gardens, Glasgow, Lead Works Manager.
1883. Taylor, Jas., "Adderton," Dundas, N.S.W., Australia, Government Metallurgist.
1898. Taylor, Jas. M., Tynevale, Groes Road, Cressington, Liverpool, Analytical Chemist.
1901. Taylor, Jno., c/o Brotherton and Co., Ltd., Tar Works, Litherland, Liverpool, Chemist.
1888. Taylor, J. Scott, North London Colour Works, Spring Place, Kentish Town, N.W., Technical Chemist.
1896. Taylor, Martin, "The Clough," Buckhurst Hill, Essex, Chemical Works Manager.
1901. Taylor, Sidney H., 65, Newbridge Road, Weston, Bath, Works Chemist.
1898. Taylor, Walter, 475, Grosvenor Place, Limefield, Bury, Lancs., Technical Chemist.
1905. Taylor, Wm. H., 36, Glenhouse Road, Eltham Park, Kent, Chemist.
1887. Teanby, G. W. A., Elvin Lodge, East Dereham, Norfolk, Analytical Chemist.
1899. Teas, Wm. Holmes, Ridgeway, Pa., U.S.A., Chemist.
- O.M. Teed, Dr. F. L., Chem. Lab'y., 9, Mining Lane, London, E.C., Analytical Chemist.
1905. Teeple, Dr. J. E., 50, Church Street, New York City, U.S.A., Director.

1908. Teichfeld, Arnold, Pruszkow, near Warsaw, Russian Poland, Chemist in Ceramic Industry.
1904. Teller, George L., The Columbus Laboratories, 103, State Street, Chicago, Ill., U.S.A., Chemist.
1906. Tempany, Harold A., Government Laboratory, St. John's, Antigua, West Indies, Analyst.
1884. Tennant, Jas., Alex. Fergusson and Co., Ltd., 34-38, McAlpine Street, Glasgow, Lead and Colour Manufacturer.
1896. Tennille, Geo. F., c/o Southern Cotton Oil Co., 206, Bay Street East, Savannah, Ga., U.S.A., Chemist.
1908. Terleski, Fred. H., 28, Hugh Oldham Drive, The Cliff, Manchester, Technical Chemist.
1884. Terry, Hubert L., (Journals) 3, Herbert Street, Moss Side, Manchester; and (Laboratory) 23, Hopwood Avenue, Manchester, Technical Chemist.
- O.M. Tervet, R., 68, Windsor Road, Leyton, Essex, Oil Works Manager.
1893. Tetley, C. F., Messrs. Jos. Tetley and Son, The Brewery, Leeds, Brewer.
1897. Tetlow, Dr. Wm. E., Ash Cottage, Ashfield, Dunblane, N.B., Chemist.
1908. Thatcher, Dr. C. J., 1352, Hudson Terminal Building, New York City, U.S.A., Consulting Chemist and Patent Expert.
1903. Thatcher, Ed. J., The Manor House, Chew Magna, near Bristol, Merchant and Manufacturer.
1908. Theis, Dr. Fred. C., Königsteinerstrasse 60, Höchst a/Main, Germany, Chemist.
1908. Thiele, Dr. Ludwig, Holland, Mich., U.S.A., Manager, Holland Gelatine Works.
1908. Thom, Wm. H., 78, Dunn Avenue, Toronto, Canada, Chemist.
- O.M. Thomas, Chas., J.P., D.L., Pitch and Pay, Stoke Bishop, near Bristol, Soap Manufacturer.
1894. Thomas, H. Russell, Broad Plain Soap Works, Bristol, Soap Manufacturer.
- O.M. Thomas, J. W., Overdale, Shortlands, Kent, Analytical Chemist.
1902. Thomas, Nehemiah M., Roseville Avenue, Pymble, N.S.W., Australia, Inspector.
1901. Thomas, Octavius, Gas and Water Offices, Pentre, Glamorganshire, Gas and Water Engineer.
1908. Thomas, Oswald J. D., 65, Clarendon Gardens, Hford, Essex, Analytical Chemist.
1888. Thomas, S. Percy, 2, Landrock Road, Hornsey, N., Technical Chemist.
1898. Thomas, Wm. Harrison, jun., Mount Royal Spinning Co., St. Paul, Montreal, Canada, Printworks Chemist.
1905. Thomlinson, Wm., Seaton Carew Ironworks, West Hartlepool, Ironmaster.
1885. Thompson, Prof. Claude M., 38, Park Place, Cardiff, Professor of Chemistry.
1898. Thompson, Edw. C., 32, Ulundi Road, Westcombe Park, S.E., Manufacturing Chemist.
1909. Thompson, Edwin, 1, Crextheth Grove, Liverpool, Manufacturing Chemist.
1893. Thompson, G. Rudd, 69, Dock Street, Newport, Mon., Analytical and Consulting Chemist.
1895. Thompson, Gustave W., 129, York Street, Brooklyn, N.Y., U.S.A., Chemist.
1907. Thompson, Jas. G., Donegall Quay Mills, Belfast, Ireland, Corn Miller.
1903. Thompson, Jno. T., Corporation Sewage Works, Knostrop, Leeds, Analyst.
1907. Thompson, Milton S., 72, Broad Street, Boston, Mass., U.S.A., Manufacturer.
1885. Thompson, W., Sankey Hill, Earlestown, Lancashire, Sugar Refiner.
- O.M. Thompson, W. P., Patent Office, 6, Lord Street, Liverpool, Patent Agent.
1896. Thomsen, Alonzo L., Maryland Club, 1, East Eager Street, Baltimore, Md., U.S.A., Manufacturing Chemist.
1884. Thomson, G. Carruthers, 53, Bedford Road, Rock Ferry, Birkenhead, Engineer.
1907. Thomson, H. N., P.O. Box 227, Anaconda, Montana, U.S.A., Metallurgist.
1891. Thomson, Jas. M., Royal Gunpowder Factory, Waltham Abbey, Essex, Manager (Cordite Branch).
1884. Thomson, Robt. T., 156, Bath Street, Glasgow, Analytical Chemist.
1899. Thomson, Thos., c/o Waterproofing Co., Barrhead, near Glasgow, Manufacturer.
- O.M. Thomson, W., Royal Institution Laboratory, Manchester, Analytical and Consulting Chemist.
1890. Thomson, Wm. Thos., Royal Gunpowder Factory, Waltham Abbey, Essex, Explosives Chemist.
1902. Thorburn, Jas., 30, Cromartie Avenue, Newlands, Glasgow, Analytical Chemist.
1908. Thornber, Wm., Green Lane Chem. Works, Padiham, Lancs., Manufacturing Chemist.
1908. Thorne, Arthur T., c/o Dr. Dunn, 20, Woodbine Avenue, Gosforth, Newcastle-on-Tyne, Student.
- O.M. Thorne, Dr. L. T., 2, Denbigh Gardens, Richmond-on-Thames; and (Journals) Southampton Wharf, Battersay, S.W., Technical Chemist.
1907. Thornwell, A. R., 352, Oldbury Road, West Smethwick, Birmingham, Works Chemist.
- O.M. Thomeycroft, Wallace, Pleau House, Pleau, Stirling, Technical Chemist.
1904. Thornley, Thomas, 19, Hope Street, Glasgow, Chemical Manufacturer.
1907. Thornton, A. D., 13, Tupper Street, Montreal, Canada, Rubber Goods Manufacturer.
1891. Thornton, Chris., 26, Larch Street, Providence, R.I., U.S.A., Printworks Manager.
1891. Thornton, David H., Brookfoot Dyeworks, Brighouse, Yorks., Dyer.
1887. Thornton, H., Redbourn, Ashford, Middlesex, Analytical Chemist.
1899. Thornton, Wm., Hermand, West Calder, N.B., Chemist.
1895. Thorp, Dr. Frank H., Mass. Inst. of Technology, Boston, Mass., U.S.A., Assistant Professor of Industrial Chemistry.
1907. Thorp, Thos., Moss Bank, Whitefield, near Manchester, Engineer.
1906. Thorp, Walter, Sorrentoville, Dalkey, Co. Dublin, Ireland, Analytical Chemist.
1905. Thorpe, Dr. J. F., F.R.S., Yarnaford, Heaton, Mersey, Lancs., Lecturer, Manchester University.
- O.M. Thorpe, Dr. T. E., C.B., F.R.S., Government Laboratory, Clement's Inn Passage, Strand, W.C.; and (Journals) 61, Ladbroke Grove, Notting Hill, W., Chief Chemist (Customs and Inland Revenue).
1905. Thresh, Dr. John C., Chelmsford, Essex, Medical Officer of Health and Sanitary Expert.
1902. Thurlow, Nathaniel, 78, Warburton Avenue, Yonkers, N.Y., U.S.A., Chemist.
1898. Thurnauer, Dr. Gustav, c/o Aurora Metal Co., Aurora, Ill., U.S.A., Chemist.
1904. Thurston, Azor, Grand Rapids, Ohio, U.S.A., Chemist.
1908. Thwaites, John H., Market Chambers, Peterborough, Chemical Engineer.
1904. Tickle, Thos., Laboratory, 83, Queen Street, Exeter, Analyst.
1903. Tighe, Arthur, Inverarie, Pymble, Sydney, N.S.W., Australia, Chemist.
- O.M. Tilden, Prof. W. A., F.R.S., The Oaks, Murray Road, Northwood, Middlesex, Professor of Chemistry.
1908. Tillberg, Erik W., Westervik, Sweden, Extract Manufacturer.
1900. Tilley, Jas. W., 95A, Southwark Street, London, S.E., Research Chemist.
1906. Tillson, Henry E., 75, Abbott Street, Laurence, Mass., U.S.A., Dyer.
1901. Timmans, W. G., c/o Basford Chemical Co., Basford, Nottingham, Chemical Works Manager.
- O.M. Timmis, T. Sutton, Widnes, Chemical Manufacturer.
1905. Tindall, W. B., 39, St. Mary Street, Toronto, Canada Secretary and Treasurer.
1907. Tingle, Dr. J. B., McMaster College, Toronto, Canada, and (Journals) Y. L. Kwong, Tao Tai Bureau of Mines, Chinanfu, Shantung, China, Professor of Chemistry.

1908. Tingle, J. Grantley, c/o Pacific Phosphate Co., Ltd., A.M.P. Building, Collins Street, Melbourne, Victoria, Assayer.
1891. Tipler, Fred. C., 48, Brooklyn Street, Crewe, Analytical Chemist.
1907. Tischbein, Dr. Robert, The Heyden Chemical Works, Garfield, N.J., U.S.A., Chemist.
1890. Tobey, C. H., Burks Falls, Ontario, Canada, Tannery Chemist.
1894. Toch, Maximilian, 52, 9th Street, Long Island City, N.Y.; and (Journals) 320, Fifth Avenue, New York City, U.S.A., Chemist.
1886. Todd, A. M., c/o The A. M. Todd Co., Kalamazoo, Mich., U.S.A., Manufacturing Chemist and Distiller of Essential Oils.
1905. Tolson, Stanley, The Croft, Abbey Wood, S.E., Chemist.
- O.M. Toms, F. Woodland, States Analyst's Office, St. Heliers, Jersey, Analytical Chemist.
1902. Tone, Frank Jerome, c/o The Carborundum Co., Niagara Falls, N.Y., U.S.A., Manager.
1896. Tonkin, John, Hermon, St. Lawrence Co., N.Y., U.S.A., Manufacturing Chemist.
1909. Tonry, Wm. S., 614, West 136th Street, New York City, U.S.A., Chemical Engineer.
1907. Torrey, Dr. Joseph, Craigie Lea, Blundellsands, Liverpool, Engineer.
1905. Torrey, Prof. H. A., Harvard Chemical Laboratory, Cambridge, Mass., U.S.A., Assistant Professor of Chemistry, Harvard University.
- O.M. Towers, J. W., Widnes, Lancashire, Analytical Chemist.
1907. Towler, A. E., c/o Sulphide Corporation, Cockle Creek, near Newcastle, N.S.W., Australia.
1909. Townsend, Harry, Public Library, Bury, Lancashire, Librarian.
1892. Townsend, Chas. W., 19, Crawford Street, Port Dundas, Glasgow, Chemical Manufacturer.
1897. Towse, Walter, 14, Ivy Road, Gosforth, Newcastle-on-Tyne, Technical Chemist.
1904. Toyne, Francis D., c/o Kelsall and Kemp, Ltd., Woodhouse Mills, Norden, near Rochdale, Chemist.
1899. Tranton, Dr. Wm., Hawthorne Lodge, Letchford, near Warrington, Chemist.
1894. Traphagen, Dr. Frank W., Colorado School of Mines, Golden, Colo., U.S.A., Professor of Metallurgy and Assaying.
1900. Traquair, Jno., Glenfield Starch Works, Paisley, N.B., Analytical Chemist.
1906. Travell, Norman E., 26, Forest Road, Nottingham, Lace Dresser.
1905. Travelli, Chas. I., United Printing Machinery Co., 246, Summer Street, Boston, Mass., U.S.A., Mechanical Engineer.
1893. Travers, Prof. Morris W., F.R.S., Indian Institute of Science, Bangalore, India, Professor of Chemistry.
1889. Trechmann, A. O., Halling Lime and Cement Works, near Rochester, Kent, Cement Manufacturer.
1885. Trechmann, Dr. C. O., Warren Cement Works, Hartlepool, Cement Manufacturer.
1895. Trehame, F. Gwilym, Wrangbrook, Llanishen, near Cardiff, Analytical Chemist.
1885. Trewby, Herbert, 62, St. John Street, London, E.C., Analytical Chemist.
1909. Trier, Thorvald G., 237, West 22nd Street, New York City, U.S.A., Technical Chemist.
1901. Trigger, Oliver, Chem. Dept., Royal Arsenal, Woolwich, S.E., Analytical Chemist.
1898. Tripp, Dr. E. Howard, 73, Waldeck Avenue, Bedford, Science Master.
- O.M. Trobridge, A., c/o Trobridge and Co., Ltd., Heworth Shore, Felling-on-Tyne, Technical Chemist.
1907. Trostel, Geo. M., Canton, N.C., U.S.A., Chemist.
1897. Trotman, Saml. R., The City Laboratory, 1, Regent Street, Nottingham, City Analyst.
1900. True, Percival E., 279, Douglas Avenue, Elgin, Ill., U.S.A., Chemical Engineer.
1887. Tsukiyama, S., 2nd of No. 2116, Fukiai-chō, Kobe, Japan, Paper Mills Chemist.
1894. Tucker, Alex. E., Norwich Union Chambers, Congreve Street, Birmingham, Metallurgist and Chemist.
1897. Tucker, Samuel A., Columbia University, New York City, U.S.A., Tutor in Industrial Chemistry.
1907. Tudor-Williams, G., 90, Galsbys Road, Aberdare, South Wales, Chemist.
1886. Tuer, Arthur H., Douglas House, Worthington, near Wigan, Analytical Chemist.
1903. Tufts, C. G., c/o Smet-Solvay Co., Syracuse, N.Y., U.S.A., Chemical Engineer.
1907. Tufts, John L., 15, Park Avenue, Winchester, Mass., U.S.A., Chemical Engineer.
1901. Tulloch, Wm. F., 7, West George Street, Glasgow, Merchant.
1904. Tunnell, Raymond W., 251, West Walnut Lane, Germantown, Philadelphia, Pa., U.S.A., Manufacturer.
1899. Turnbull, Dr. Andrew, 18, Hackins Hey, Liverpool, Consulting Chemist.
1888. Turnbull, G.W., Ash Cottage, North Road, Carnforth, Lancashire, Metallurgical Chemist.
1905. Turnbull, John, 66, Jarvis Street, Toronto, Canada, Manufacturer of Food Products.
1904. Turnbull, R. H., c/o MacAndrews and Forbes Co., Camden, N.J., U.S.A., Analytical Chemist.
1884. Turnbull, W. S., 37, West George Street, Glasgow, Chemical Manufacturer.
1902. Turner, Basil, 83, Pitt Street, Sydney, N.S.W., Australia, Metallurgist.
1902. Turner, Jos., c/o Read Holliday and Sons, Ltd., Huddersfield, Chemist.
1905. Turner, Prof. Thomas, Springfield, Upland Road, Selly Park, Birmingham, Professor of Metallurgy.
1897. Turney, Fred. N., 10, Dieghem Straat, Saventhum, near Brussels, Belgium, Leather Dresser.
1887. Turney, Sir J., Trent Bridge Leather Works, Nottingham, Tanner.
1908. Turnill, Thos. W., c/o Major and Co., Sealecoates, Hull, Works Chemist.
1906. Tuttle, Dr. Franklin E., 125, East Maxwell Street, Lexington, Ky., U.S.A., Professor of Chemistry.
1903. Tutton, Henry Ralph, 12, Woodland Place, Penarth, S. Wales, Chemist.
1905. Tutwiler, Carrington C., 1706, North Broad Street, Philadelphia, Pa., U.S.A., Chemist.
1890. Tweedy, Jas., 245, Burdett Road, Limehouse, E., Metallurgical Chemist.
1905. Twigg, Geo. F., 29, Fairfax Road, Derby, Gas Works Chemist.
1891. Twitchell, E., Wyoming, Ohio, U.S.A., Candle Works Manager.
1897. Twynam, H., O.K. Copper Mine, *via* Cairns, Queensland, Australia, Mining Engineer.
- O.M. Twynam, T., Wynyard House, Chatham Road, Redcar, Yorks., Metallurgist.
1904. Tyler, Chas. R., c/o Dr. Francis Wyatt, 402, West 23rd Street, New York City, U.S.A., Analytical Chemist.
- O.M. Typke, P. G. W., Lawn House, New Malden, Surrey, Chemical Manufacturer.
- O.M. Tyrer, Thos., Stirling Chemical Works, Stratford, E.; and (Journals) 14, Sandwell Mansions, West End Lane, N.W., Chemical Manufacturer.
1899. Tysoe, Jos., South Metropolitan Gas Co., East Greenwich, S.E., M.Inst.C.E., Gas Engineer.

U

1907. Udal, John P., Ridge Road, Berea, Durban, Natal, Engineer.
1894. Uhlig, E. C., Citizens' Gas Works, Fifth and Hoyt Streets, Brooklyn, N.Y., U.S.A., Chemist.
1900. Uhlig, W. C., c/o Hygeia Distilled Water Co., 349, West 12th Street, New York City, U.S.A., Chemist.
- O.M. Umney, C., (Journals) Fernbrake, Branksome, Wood Road, Bournemouth; and (communications) 50, Southwark Street, London, S.E., Manufacturing Chemist.

1905. Umney, John C., 48, Southwark Street, London, S.E., Wholesale Druggist.
 1889. Underhill, Thos. J., "Stanley," Quernmore Road, Bromley, Kent, Inspector of Stores.
 1885. Underwood, G. R., 4, Emerson Street, Peabody, Mass., U.S.A., Glue Works Chemist.
 1908. Underwood, Norman, Bureau of Engraving and Printing, Treasury Dept., Washington, D.C., U.S.A., Chemist.
 1908. Unglaub, Adolf, 5120, Chestnut Street, Philadelphia, Pa., U.S.A., Chemical Engineer.
 1908. Upton, Wm. C., Sara Cook Street, Rawdwick, N.S.W., Australia, Soap and Candle Manufacturer.
 1883. Usmar, J. H., 22, Billiter Street, London, E.C., Chemical Merchant.
 1904. Uyeda, Toyokitsu, Takasago, Harima, Japan, Chemist.

V

1907. Vail, Jas. G., c/o Philadelphia Quartz Co., Delaware Avenue and Howell Street, Chester, Pa., U.S.A., Chemist.
 1896. Van der Linde, Harold, c/o Continental Rubber Co., 111, Broadway, New York City, U.S.A., Chief Chemist.
 1895. Vanderpool, Dr. Frank, 175, Park Avenue, Orange, N.J., U.S.A., Chemist.
 1903. Van Dyck, Edwin M., c/o Ault & Wiborg Co., 534, Pearl Street, New York City, U.S.A., Chemist and Ink Maker.
 1907. Van Essen, E. C., c/o Hemingway and Co., Marsh Gate Lane, Stratford, E., Technical Chemist.
 1897. Van Gelder, Arthur P., c/o E. I. du Pont de Nemours Powder Co., Landing, N.J., U.S.A., Superintendent.
 1891. Van Gundy, Chas. P., Laboratory, B. and O. R. R., Baltimore, Md., U.S.A., Metallurgical Chemist.
 1896. Van Laer, Norbert, Truman's Brewery, Burton-on-Trent, Brewer and Chemist.
 1897. Van Marken, J. C., Repelen, near Moers, Germany, Chemical Engineer.
 1908. Van Trump, Isaac, c/o The Barber Asphalt Paving Co., 1245, Stock Exchange Building, Chicago, Ill., U.S.A., Chemist.
 1888. Vargas-Vergara, J. M., Apartado No. 237, Bogota, Colombia, S. America, Metallurgical Chemist.
 1905. Varshnei, Ishwar Das, Talegaon, G. I. P. Railway, Poona District, India, Chemical Engineer.
 1898. Verity, Ben, Magog, Prov. Quebec, Canada, Print Works Chemist.
 1897. Verity, Victor, 12, Gladstone Street, East Boston, Mass., U.S.A., Chemical Works Foreman.
 1904. Vernon, R. H., Institut Erixa, Rothelstrasse, Zürich, Switzerland, Student.
 1907. Vial, Stanley B., University High School, Melbourne, Victoria, Australia, Principal.
 1908. Vickers, Benj. Trefall, Gascoigne Street, Boar Lane, Leeds, Oil Merchant.
 O.M. Vickers, Wm., c/o Thos. Vickers and Sons, Miles Platting, Manchester, Chemical Manufacturer.
 1907. Vietinghoff-Scheel, Dr. Karl Freiherr von, "Chemiker-Zeitung," Cöthen (Anhalt), Germany, Editor in Chief.
 1908. Vieweg, Dr. Walter, Steinheimer Landstrasse 20, Hanau a/M., Germany.
 1897. Vlies, Leonard E., Belmont, Gowan Road, Alexandra Park, Manchester.
 O.M. Voelcker, E. W., 22, Tudor Street, London, E.C., Analytical and Consulting Chemist.
 1887. Voelcker, Dr. J. A., 20, Upper Phillimore Gardens, Kensington, W., Agricultural Chemist.
 1901. Vogel, G. C., c/o Plister and Vogel Leather Co., Milwaukee, Wis., U.S.A., Tanner.
 1897. Vogel, Julius L. F., Hillersdon, East Molesey, Surrey, Engineer.
 1899. Vogeler, Gustav, 17, Philpot Lane, London, E.C., Merchant.

1897. Voorhees, Louis A., 111, Carroll Place, New Brunswick, N.J., U.S.A., Agricultural Chemist.
 1899. Voorhees, Samuel S., Technologic Branch, U.S. Geological Survey, Washington, D.C., U.S.A., Chemist.
 1902. Vorisek, Dr. Anton, College of Pharmacy, 115-119, West 68th Street, New York City, U.S.A., Instructor.
 1888. Vörster, Fritz, Cöln-Marienburg, Germany, Manufacturing Chemist.
 1885. Voss, Hermann, 19, Beekenharn Road, Beekenharn, Kent, Manure Works Manager.
 1899. Voss, Walter A., Eastwood Road, Rayleigh, Essex, Manufacturing Chemist.

W

1896. Wachtel, Gregory, Alexandrowski Prospect 21, St. Petersburg, Russia, Chemical Engineer.
 1904. Wackenreuter, A. G., 134-136, Kinzie Street, Chicago, Ill., U.S.A., Colour Manufacturer.
 1905. Waddell, Montgomery, 1, West 101st Street, New York City, U.S.A., Consulting Engineer.
 1902. Wade, Frank, 26, St. Roman's Avenue, Southsea, Analytical Chemist.
 1890. Wade, Jas. L., 28, West Kensington Gardens, London, W., Chemical Manufacturer.
 1889. Wadman, W. E., 102, Lord Avenue, Bayonne, N.J., U.S.A., Manufacturing Chemist.
 1897. Wagner, Dr. Theodore B., 14, Marquette Terrace, Chicago, Ill., U.S.A., Chemist.
 1893. Wagner, W. G., 12, North Common Road, Ealing, W., Manufacturing Chemist.
 1906. Wagstaffe, Dr. E. A., 22, Blackfriars Street, Manchester, Analytical Chemist.
 1906. Wahl, Dr. Robert, 327, Fullerton Avenue, Chicago, Ill., U.S.A., President, Brewer's School.
 1903. Wainwright, J., 15, Bolton Road, Port Sunlight, near Birkenhead, Soap Works Manager.
 1884. Wainwright, Dr. J. H., 22, West 46th Street, New York City, U.S.A., Analytical Chemist.
 1906. Wainwright, R. E., Woodside Dyeworks, Horsforth, near Leeds, Dyer.
 1895. Wainwright, Wm., c/o Spooner and Bailey, Manure Works, Eling, near Southampton, Chemist.
 1908. Wait, Douglas, c/o R. Gay and Co., Ltd., Langthorne Works, Stratford Market, London, E., Analytical Chemist.
 1901. Waite, C. Nelson, c/o The Jessup & Moore Paper Co., Delaware Mills, Wilmington, Del., U.S.A., Chemist.
 1899. Wakefield, Wm. C., Overthorpe, Thornhill, near Dewsbury, Chemist.
 1905. Waldenberger, Dr. C. A., c/o Independent Baking Powder Co., 322-328, Warren Street, Jersey City, N.J., U.S.A., Chemist.
 1894. Waldman, Louis J., P.O. Box 162, Albany, N.Y., U.S.A., Aniline Dye Manufacturer.
 1895. Waldstein, Dr. Martin E., 100, William Street, New York City, U.S.A., Manufacturing Chemist.
 1887. Walker, Archibald, 8, Crown Terrace, Glasgow, Distiller.
 1908. Walker, George, c/o Burmah Oil Co., P.O. Box 67, Rangoon, Burmah, Analytical Chemist.
 1897. Walker, H. V., 586, St. Mark's Avenue, Brooklyn, N.Y., U.S.A., Chemist.
 1894. Walker, Dr. Jas., University College, Dundee, Professor of Chemistry.
 1897. Walker, Jas. W., Marine Lodge, Irvine, N.B., Chemical Manufacturer.
 1906. Walker, Jas. W., Stonydale, Oakmoor, Stoke-on-Trent, Assayer.
 1902. Walker, Jno. H., Gourepore Works, Naihati, E.B.S.R., Bengal, India, Chemist.
 1884. Walker, S. R., Fern Bank, Starling Road, Radcliffe, Manchester, Foreman Dyer.
 1900. Walker, Dr. Wm. H., Mass. Institute of Technology, Boston, Mass., U.S.A., Chemical Expert.

1895. Walker, W. Sloane, c/o Walker, Ltd., Litherland, near Liverpool, Tanner.
1897. Wallace, Edwin C., P.O. Box 241, East Auburn, Cal., U.S.A., Chemist.
1897. Wallace, Robt. A., 12, Avonmore Mansions, West Kensington, W., Chemical Manufacturer.
1883. Wallace, Robert, 20, Murrayfield Avenue, Edinburgh, Distiller.
- O.M. Waller, Dr. Elwyn, 7, Franklin Place, Morristown, N.J., U.S.A., Professor of Chemistry.
1906. Wallerstein, Leo, 105, East 91st Street, New York City, U.S.A., Chemist.
1899. Wallerstein, Dr. Max, 105, East 91st Street, New York City, U.S.A., Chemist.
1886. Walsh, F. T., 12, Valentine Street, West Newton, Mass., U.S.A., Colour Printer.
1901. Walsh, Lionel O.P., c/o Burt, Boulton and Haywood, Ltd., Prince Regent's Wharf, Silvertown, E., Chemist.
1903. Walsh, Peter H., P.O. Box 469, Magog, Quebec, Canada, Analytical Chemist.
1907. Walsh, Philip C., 19, Grant Street, Newark, N.J., U.S.A., Electro-Chemist and Metallurgist.
1904. Walther, Wm., Holzappel's Compositions Co., Ltd., Heworth Shore, Felling-on-Tyne, Chemist and Works Manager.
1908. Walton, Robert H., Railway Stores, Eveleigh, Sydney, N.S.W., Analyst.
1902. Walton, Thos. U., Colonial Sugar Refining Co., Ltd., O'Connell Street, Sydney, N.S.W., Australia, Analytical Chemist.
1895. Want, W. Philip, 44, Bishopsgate Street Without, London, E.C., Pharmacist and Editor.
1901. Warburton, Frank, 50, Rosebery Road, Muswell Hill, N., Manager.
1904. Warburton, George H., 366A, High Road, Brondesbury, N.W., Analytical Chemist.
1896. Warburton, Thos., 98, Stanley Grove, Longsight, Manchester, Chemist.
1903. Ward, Dudley R., Mysore Gold Mine, Marikuppam, Mysore State, South India, Analytical Chemist.
- O.M. Ward, Geo., Messrs. Hirst, Brooke, and Hirst, Ltd., Millgarth Mills, Leeds, Chemical Manufacturer.
1891. Ward, G. J., Hallam Fields, Ilkeston, Notts., Civil Engineer.
1884. Ward, Howard Chas., Yeatton, Hordle, Lymington, Hants., Deputy Chairman of Gas Co.
1898. Ward, John, Barnstone Blue Lias Lime Co., Ltd., Barnstone, Notts., Manager.
1899. Ward, Wm. J., Chemist.
1906. Wardlaw, Thos. D., c/o The Geigy Aniline and Extract Co., 60, Front Street West, Toronto, Canada, Manager.
1908. Wardleworth, Theo. H., 168, Côte Saint Antoine Road, Westmount, Montreal, Canada, Manufacturing Chemist.
1902. Waring, W. Geo., Webb City, Mo., U.S.A., Metallurgical Chemist.
1899. Warnes, Arthur R., c/o Josiah Hardman Ltd., Aston Church Road, Nechells, Birmingham, Chemist.
1890. Warren, Fiske, c/o S. D. Warren and Co., Cumberland Mills, Westbrook, Maine, U.S.A., Paper Manufacturer.
1902. Warren, H. D., Laboratory, Gutta Percha and Rubber Manufacturing Co., Ltd., 47, Yonge Street, Toronto, Canada, President.
1901. Warren, Jno. E., Eagle Chemical Works, Barchester Street, Poplar, E., Tar Distiller.
1907. Warren, W. H., Gas Works, Beckton, E., Gas Engineer.
1885. Waterfall, W. B., c/o Avon Manure Co., Bristol; and (Journals) Thirlmere, Clavering Road, Redland, Bristol, Manure Manufacturer.
1902. Watkins, E. J., (communications) 10, Montpelier Road; and (Journals) c/o Mellin's Food, Ltd., Stafford Street, Peckham, S.E., Works Chemist.
1898. Watkins, Willard H., c/o Schoellkopf, Hartford, and Hanna Co., P.O. Drawer 57, Buffalo, N.Y., U.S.A., Chemist.
1894. Watmough, Benj. I., Ryeburn, Stanley Road; and (Journals) c/o Brotherton and Co., Ltd., Ammonia Works, Wakefield, Chemist.
1894. Watson, Alex. Forbes, St. James's Gate Brewery Laboratory, Watling Street, Dublin, Chemist.
1884. Watson, Chas., Fairfield, Washwood Heath Road, Birmingham, Manufacturing Chemist.
1894. Watson, Chas. Ernest, 28, Highfield Road, Stretford, Manchester, Chemical Assistant.
1908. Watson, C. I. Wilkinson, 20, Finlay Drive, Dennistoun, Glasgow, Chemist.
1890. Watson, Eric E., (Journals) c/o Straits Trading Co., Singapore, S.S.; (subs.) c/o S. Watson, Queen Insurance Buildings, Dale Street, Liverpool, Chemist.
1901. Watson, Herbert J., 38, Peel House Lane, Widnes, Chemist.
1903. Watson, H. W., c/o H. Hogarth, Denton Avenue, Gledhow, Leeds, Analytical Chemist.
1903. Watson, Hugh M., 22, Coleraine Road, Blackheath, S.E., Paint Manufacturer.
1894. Watson, Jas., Tyne View, Hebburn-on-Tyne, Alkali Works Manager.
1905. Watson, James, 41, Sherburn Street, Holderness Road, Hull, Manager.
1891. Watson, Jno., Langdon, Beaconsfield Road, Blackheath, S.E., Analytical Chemist.
- O.M. Watson, Jno. C., c/o Oriental Silk Printing Co., Paterson, N.J., U.S.A., Manager.
1904. Watson, Percy, 554, Somerset Avenue, Taunton, Mass., U.S.A., Chemist and Dyer.
- O.M. Watt, A., c/o Macfie and Sons, 34, Moorfields, Liverpool, Sugar Works Chemist.
1901. Watt, Francis L., 10, Northcote Chambers, Reiby Lane, Circular Quay, Sydney, N.S.W., Australia, Analytical Chemist.
1906. Watt, Dr. H. E., Imperial Institute, South Kensington, S.W., Chemist.
1904. Watt, John, 17, Maple Avenue, Toronto, Ont., Canada, Glass Manufacturer.
1893. Watts, Jno. Isaac, Fairleigh, Hartford, Cheshire, Alkali Works Manager.
1908. Watts, Jno. Wm., Newcastle Tar Works, Blaydon-on-Tyne, Manager.
1907. Waumsley, Harry, Monckton Maine Colliery, near Barnsley, Chemical Engineer.
1903. Wayland, Wm. A., 12, Albert Road, Brockley, S.E., Manufacturing Chemist.
1906. Webb, E. A., Woodbine and Burgess Avenues, Toronto, Canada, Technical Chemist.
1906. Webb, Frank H., 7, Dustin Street, Haverhill, Mass., U.S.A., Chemist.
1900. Webb, Jno. F., 20, Louvaine Road, St. John's Hill, Battersea, S.W., Mining and Electrical Engineer.
1905. Webber, W. J., 55, Kilby Street, Boston, Mass., U.S.A., Manufacturing Chemist.
1901. Webster, Geo. J., 115, Delaware Avenue, Toronto, Canada, Secretary.
1902. Webster, Jno., Chemical Laboratory, Guy's Hospital, London, S.E., Analyst.
1908. Webster, John H., 47, Horace Street, St. Helens, Lancs., Metallurgist and Salt Works Manager.
1906. Weddell, George, 20, Grainger Street West, Newcastle-on-Tyne, Manufacturing Chemist.
1904. Wedekind, Rud., Uerdingen, Niederrhein, Germany, Manufacturer of Alizarin and Bichromates.
1897. Wedge, Utley, Pennsylvania Salt Manufacturing Co., Philadelphia, Pa., U.S.A., Chemist.
1902. Weed, Hy. T., 181, Prospect Park West, Brooklyn, N.Y., U.S.A., Teacher of Chemistry.
1893. Weeks, H. B., 2, Infield Park Road, Barrow-in-Furness, Analytical Chemist.
1898. Weeple, Lawrence, Pinchin's Wharf, Stratford, E., Colour Works Chemist.
1904. Weil, Jacob A., c/o The Power Gas Corporation, Ltd., 39, Victoria Street, Westminster, S.W., Chemist.
1902. Weiskopf, Dr. Erich, Dynamit Factory, Modderfontein, Transvaal, South Africa, Chemist.

1908. Weissmüller, Edward F., Hill Crest, Runcorn, Chemist.
1905. Weissmüller, Ernest C., Hill Crest, The Heath, Runcorn, Cheshire, Research Chemist.
1899. Weldon, Leonard E., 151, Egypt Road, New Basford, Nottingham, Dyer.
1907. Welham, Samuel D., c/o Brotherton and Co., Ltd., Church Road, Litherland, near Liverpool, Technical Chemist.
1903. Wellecome, Henry S., Snow Hill Buildings, London, E.C., Manufacturing Chemist.
1891. Wells, Jas. Gray, Carlton Lawn, Chester Road, Stretford, Manchester, Brewing Chemist.
1894. Wells, Pierson L., 86, Joralemon Street, Brooklyn, N.Y., U.S.A., Patent Lawyer and Engineer.
1885. Welsh, Jas., Printworks Manager.
1890. Welsh, Thos. L., 3, Prince's Gardens, Dowanhill, Glasgow, Analytical Chemist.
- O.M. Welsh, W., Holt Town Oil Works, Manchester.
1905. Welt, Dr. Ida, 18, West 83rd Street, New York City, U.S.A., Chemist.
1906. Wenger, Francis E., Clivedon, Wolstanton, Stoke-on-Trent, Ceramic Colour Manufacturer.
1909. Wentworth, Henry A., c/o Huff Electrostatic Separator Co., 60, India Street, Boston, Mass., U.S.A., Mining Engineer.
1903. Wesener, Dr. John A., 103, State Street, Chicago, Ill., U.S.A., Consulting Chemist.
1881. Wessel, Carl, (communications) Geheimer Commerzienrath C. Wessel, Bernburg; and (Journals), Deutsche Solvay-Werke Act.-Ges., Bernburg, Anhalt, Germany, Alkali Manufacturer.
1889. Wesson, D., c/o Southern Cotton Oil Co., 24, Broad Street, New York City, U.S.A., Technical Chemist and Cotton-Oil Expert.
1908. West, Chas. A., c/o American Camphor Refining Co., 14, Fulton Street, Boston, Mass., U.S.A., President.
1903. West, Leonard, Merrywood, Belper Road, Derby, Manufacturing Chemist.
1909. West, Percy C. H., 40, The Green, Norton, Co. Durham, Analytical Chemist.
1900. Westenfelder, B. D., 924, Clinton Street, Cincinnati, Ohio, U.S.A., Chemist.
1885. Westmoreland, J. W., 12, Arthington Terrace, Hunslet, Leeds, Metallurgical Chemist.
1898. Weston, David B., Sharon, Mass., U.S.A., Chemist.
1894. Weston, Robt. S., 14, Beacon Street, Boston, Mass., U.S.A., Chemist and Bacteriologist.
1885. Weston, Wm., 2, Ulundi Road, Blackheath, S.E., Analytical Chemist.
1908. Westwood, Arthur W., The Assay Office, Birmingham, Assay Master.
1890. Wetter, Jasper, 37-39, Essex Street, Strand, London, W.C., Patent Agent.
- O.M. Whalley, L. J. de, 148, Jerningham Road, New Cross, S.E., Sugar Chemist.
1908. Wheaton, H. J., 21, Chesterton Road, Cambridge, Chemical Engineer.
1909. Wheeler, Edward, 113, Highbury Quadrant, London, N., Demonstrator of Chemistry.
1898. Wheeler, Dr. Edwd. J., 79, Chapel Street, Albany, N.Y., U.S.A., Analytical Chemist.
1903. Wheeler, Ernest, 4, Fairfield Terrace, Higher Openshaw, Manchester, Metallurgical Chemist.
1906. Wheeler, Frank G., Trenton, Mich., U.S.A., Chemist.
1907. Wheeler, R. Vernon, The Colliery, Altofts, near Normanton, Chemist.
1895. Wheelwright, Dr. E. W., 24, Stanmore Road, Edgbaston, Birmingham.
1909. Wheelwright, Franklin R., 10, Weybosset Street, Providence, R.I., U.S.A., Paper Makers' Materials Manufacturer.
1905. Whetton, John, 624, Front Street East, Toronto, Canada, Manager of Canadian Branch of Read Holliday & Sons, Ltd.
1909. Whiffen, G. Goodman, Lombard Road, Battersea, London, S.W., Chemical Engineer.
- O.M. Whiffen, Thos. J., Cerris House, West Hill, Putney, S.W., Manufacturing Chemist.
- O.M. Whiffen, W. G., Lombard Road, Battersea, London, S.W., Manufacturing Chemist.
1893. Whitaker, Mf., Newlaithes Grange, Horsforth, Leeds, Dyer.
1899. Whitaker, Milton C., 825, Monmouth Street, Gloucester City, N.J., U.S.A., Chemist.
1895. Whitaker, Thos., Aire Vale Dye Works, Newlay, near Leeds, Dyer.
- O.M. Whitaker, Thorpe, (Journals) Bradford Dyers' Association, Ltd., and 35, Pemberton Drive, Bradford, Yorks., Dyer's Chemist.
1893. White, Arthur F., 2, Melbourn Grove, Thornbury, Bradford, Yorks., Manufacturing Druggist.
1908. White, George, c/o Hull Stearine Co., Cleveland Street, Hull, Oilworks Chemist.
1901. White, H. Graham, Mere Cottage, Oxtou, Birkenhead, Works Chemist.
1889. White, Henry, 245, Western Road, Crookes, Sheffield, Manufacturing Chemist.
1898. White, Jno., County Offices, St. Mary's Gate, Derby, Public Analyst to County of Derby.
- O.M. White, Paul T., Horton Field House, West Drayton, Chemical Manufacturer.
1905. White, William, Beloeil Station, Province Quebec, Canada, Chemist.
1894. White, W. Gilchrist, 133, Tottington Road, Bury, Lanes., Calico Printer's Chemist.
1906. White, Wm. T., c/o American Hide and Leather Co., Lowell, Mass., U.S.A., Leather Manufacturer.
1903. Whitehouse, P. L., c/o W. H. Keys, Ltd., West Bromwich, Staffordshire, Oil Chemist.
1906. Whiteley, C. E., 21, Brudenell View, Leeds, Demonstrator of Chemistry.
1885. Whiteley, R. Lloyd, The Institute, West Bromwich, Staffordshire, Principal.
1892. Whiteside, Jno. L., 376, St. Helen's Road, Bolton-le-Moors, Chemical Lecturer.
1908. Whiting, Jasper, 523, Board of Trade Building, Boston, Mass., U.S.A., Chemical Engineer.
1885. Whittaker, C. J., Winthrop, Andell Road, Lytham, Lancashire, Chemical Engineer.
1904. Whittier, Charles T., 322, Warren Street, Jersey City, N.J., U.S.A., Manager.
1901. Whitton, Jas. T., c/o Nobel's Explosives Co., Ltd., Ardeer, Stevenston, N.B., Chemist.
1884. Whowell, F., Croich Hey, Tottington, Bury, Lanes., Bleacher.
1899. Wiarda, Jno. C., 259-273, Green Street, Brooklyn, N.Y., U.S.A., Manufacturing Chemist.
1897. Wiborg, F. B., The Ault and Wiborg Co., Cincinnati, Ohio, U.S.A., Manufacturer.
1890. Wickens, B. Foster, 31, Bermondsey Wall, London, S.E., Managing Director (Wickens, Pease, and Co., Ltd.).
1908. Wickes, Clarence S., 417, State Street, Camden, N.J., U.S.A., Factory Superintendent.
1905. Widmann, Eugene A., 595, Eighth Avenue, Brooklyn, N.Y., U.S.A., Dyestuff Merchant.
1904. Wieler, Eric E., Northern Assurance Buildings, Albert Square, Manchester, Chemical Merchant.
1904. Wiener, William, 624, Nelson Place, Newark, N.J., U.S.A., Analytical and Consulting Chemist.
1906. Wiffen, Henry J., 17, Albany Road, Manor Park, Essex, Manufacturing Chemist.
1883. Wiggin, W. W., Wiggin Street Works, Birmingham, Nickel Refiner.
1908. Wiggins, Elmer W., c/o E. I. du Pont Powder Co., Landing, N.J., U.S.A., Chemist.
1897. Wigglesworth, H., 25, Broad Street, New York City, U.S.A., Manufacturing Chemist.
- O.M. Wightman, C. I., Fenchurch Avenue, London, E.C., Chemical Merchant.
1906. Wikner, Sigurd A., 39, Margaret Street, Hull, Tar Works Chemist.
1899. Wild, Roland C., The Grange, New Eltham, Kent, Analytical Chemist.
1893. Wilder, F. L., Morro Velho, Villa Novo de Lima, Estado de Minas Geraes, Brazil, Assayer.
1902. Wilder, Salmon W., jun., 33, Broad Street, Boston, Mass., U.S.A., Treasurer.

1899. Wildman, Arthur J., 133, Central Park Road, East Ham, E., Chemist.
1902. Wiley, Dr. Harvey W., Bureau of Chemistry, Department of Agriculture, Washington, D.C., U.S.A., Chief.
1906. Wilke, Wm., 86, Norwood Avenue, Buffalo, N.Y., U.S.A., Chemical Engineer.
1903. Wilkie, Jno. M., 38, South Road, West Bridgford, Nottingham, Analytical Chemist.
1885. Wilkin, Sir Walter, K.C.M.G., Appold Street, Finsbury, E.C., Yeast Manufacturer.
1895. Wilkins, Charles, 40, Church Lane, Hornsey, N., Manufacturing Perfumer.
1899. Wilkins, H. A. J., c/o New Jersey Zinc Co., 576, Fifth Avenue, New York City, U.S.A., Mining Engineer.
1904. Wilkinson, Prof. J. A., Transvaal University College, P.O. Box 1176, Johannesburg, Transvaal, Professor of Chemistry.
1886. Wilkinson, J. B., Tong Street, Dudley Hill, Bradford, Yorks., Chemical Manufacturer.
1906. Wilkinson, John E., 69, Lombard Street, Toronto, Canada, Gold and Silver Refiner.
1903. Willard, C. T., 29, Chestnut Street, Newark, N.J., U.S.A., Chemist.
1893. Willcox, Benjamin, 47, Lincoln's Inn Fields, London, W.C.; (Journals), 34, Hamilton Terrace, St. John's Wood, N.W., Patent Agent.
1903. Williams, Chas. E., Thornhayes, Sleaford, Seed Crusher.
1895. Williams, David T., 42, Finsbury Square, London, E.C., Chemist.
1891. Williams, Henry J., 161, Tremont Street, Boston, Mass., U.S.A., Chemical Engineer.
1908. Williams, Herbert E., c/o Albion Chemical Co., Riverside, Charlton, Kent, Chemist.
1904. Williams, Jno. T., Engineering Building, 114, Liberty Street, New York City, U.S.A.
1904. Williams, Naboth, 28, Rolleston Street, Warrington, Technical Chemist.
1902. Williams, Percy, c/o A. J. Simons, Pontianak, Dutch West Borneo, *via* Singapore, Chemist.
1885. Williams, Rowland, Hale Cote, Albert Park, Lancaster, Analytical Chemist.
1900. Williams, Saml. H., Glastonbury, Conn., U.S.A., Soap Manufacturer.
1903. Williams, S. M., 269, Springdale Avenue, East Orange, N.J., U.S.A., Chemist.
1885. Williams, T. Howell. See Idris, T. H. W.
1884. Williams, Prof. W. Carleton, Broomgrove, Goring-on-Thames, Professor of Chemistry.
1902. Williams, Walter Scott, Arnold Printworks, North Adams, Mass., U.S.A., Chemical Engineer.
1887. Williams, W., Collingwood, Beechfield, Roby, near Liverpool, Analytical Chemist.
- O.M. Williams, W. J., 5004, Franklin Street, Frankford, Philadelphia, Pa., U.S.A., Analytical Chemist.
1894. Williamson, J. Alex., The Croft, Chase Court Gardens, Enfield, N., Analytical Chemist.
- O.M. Williamson, Robt., Low Walker, Newcastle-on-Tyne, Technical Chemist.
1903. Wills, J. Laimson, 133, Midwood Street, Brooklyn, N.Y., U.S.A., Technical and Brewing Chemist.
1905. Wills, Wm. R., 162, Main Street, Waltham, Mass., U.S.A., Dyer.
1895. Wilson, Thos. L., St. Catherine's, Ont., Canada, Electrical Engineer.
1890. Wilson, Alf., c/o Messrs. J. and E. Sturge, 18, Wheeley's Lane, Birmingham, Chemist.
1884. Wilson, Anthony W., 20, Westcott Street, Hull, Colour Works Manager.
1888. Wilson, Cecil H., c/o Sheffield Smelting Co., Ltd., Royds Mills Street, Sheffield, Chemist.
- O.M. Wilson, C. J., 11, Old Queen Street, Westminster, S.W.
1888. Wilson, Dr. David, Carbeth, Killearn, by Glasgow.
1885. Wilson, Frank, 7, Bedford Square, London, W.C., Brewer.
1903. Wilson, Geo. C., 298, Ryars Road, Hillhead, Glasgow, Chemist.
- O.M. Wilson, G. E., The Chemical Works, Oldbury, near Birmingham, Chemical Manufacturer.
1902. Wilson, Geo. W., Simmondley, Glossop, Derbyshire, Works, Chemist.
1899. Wilson, Gordon, Ballan, Kirkintilloch, N.B.; and (Journals) British Club, Mexico, D.F., Chemist and Assayer.
1886. Wilson, Jno., Tyneside, Hagley Road, Birmingham, Technical Chemist.
1896. Wilson, Jno., The Vines, Oxford Road, Runcorn, Chemical Engineer.
1909. Wilson, Jno., Battersea Polytechnic, London, S.W., Head of Chem. Dept.
1905. Wilson, J. E., c/o General Chemical Co., 25, Broad Street, New York City, U.S.A., Chemical Salesman.
- O.M. Wilson, J. H., 8, Friar's Stile Road, Richmond, S.W., Chemical Manufacturer.
1906. Wilson, J. Murray, c/o Hamilton Powder Co., Beloeil Station, Prov. Quebec, Canada, Technical Chemist.
1902. Wilson, Leonard P., 19, Widdrington Road, Coventry, Technical Chemist.
- O.M. Wilson, R. H., Egglecliffe P.O., Co. Durham, Chemical Manufacturer.
1900. Wilson, Walter A., Ardeer, Stevenston, Ayrshire, Chemist.
1908. Wilson, William James, c/o Wilson's Portland Cement Co., Ltd., Warkworth, Auckland, New Zealand, Cement Works Manager.
1890. Wilson, W. W., Dalmonach House, Alexandria, Dumbartonshire, Analytical Chemist.
1884. Wilton, Thos., Winsor House, Beckton, E., Tar Works Manager.
1901. Wing, Herbert H., Monticello, N.Y., U.S.A., Chemical Engineer.
1892. Wing, J. D., 22, William Street, New York City, U.S.A., Merchant.
1892. Wingfield, T. R., 5, Bromwich Street, Bolton, Brewer.
- O.M. Wingham, A., 43, Taswell Road, Southsea, Hants., Metallurgical Chemist.
1908. Winkler, Hermann, Metallgesellschaft, Frankfurt a/Main, Germany, Merchant.
1906. Winkler, S. M., 38 and 40, Main Street, Cincinnati, Ohio, U.S.A., Chemical Merchant.
- O.M. Winsor, P. J., Heath House, Knutsford, Cheshire, Consulting Chemist.
1907. Winsloe, Louis S., 114, The Albany, Liverpool, Manufacturing Chemist.
1892. Winstanley, Hy., Bridge House, Cheadle Hulme, Cheshire, Technical Chemist.
1886. Winstone, E. H., Members' Mansions, 36, Victoria Street, London, S.W., Ink Manufacturer.
1907. Winther, Dr. A., Chemische Fabrik Griesheim-Elektron, Werk Oehler, Offenbach a/Main, Germany, Chemist.
1892. Wirtz, Dr. Quirin, 28, Great Ormond Street, London, W.C., Consulting Chemist.
1900. Wishart, Harlan L., Washburn, Wis., U.S.A., Chemist.
1889. Wishart, Jno., 39, St. Vincent Place, Glasgow, General Manager (Oakbank Gil Co., Ltd.).
1902. Withers, Prof. W. A., State A. and M. College, West Raleigh, N.C., U.S.A., Professor of Chemistry.
1906. Withey, Wm. S., Eldorado Banket Gold Mine, Lomagundi, South Rhodesia, South Africa.
- O.M. Witt, Dr. Otto N., Eberschenallee 10, Westend, bei Berlin, Professor of Chemistry.
1892. Witthaus, Dr. R. A., Cornell Medical College, 470, First Avenue and 28th Street, New York City, U.S.A., Professor of Chemistry.
1907. Wolcott, Townsend, 39, Whitehall Street, New York City, U.S.A.
1901. Wolf, August S., 206, West 95th Street, New York City, U.S.A., Chemist.
1903. Wolf, Jacques, c/o Jacques Wolf and Co., Passaic, N.J., U.S.A., Manufacturing Chemist.
1891. Woltereck, Dr. H. C., 3, Edinburgh Mansions, Howick Place, London, S.W., Consulting Chemist.

1903. Wolton, Wm. R., c/o Joseph Fison and Co., Ltd., Ipswich, Manager.
1906. Wood, E. Escoff, Hurricane House, Brymbo, near Wrexham, North Wales, Chemist and Metallurgist.
1900. Wood, Frank, Hazelhurst, Doneaster Road, Barnsley, Yorks., Assistant Manager (Glass Works).
1901. Wood, Frank S., Chin Chin, Heathcote Street, Newland, Hull, Cement Works Chemist.
1887. Wood, Jos. T., 62, Park Road, Nottingham, Tanner.
1886. Wood, Wm., 20, Rue Général van Merlen, Antwerp, Belgium, Bleacher and Dyer.
1908. Woodbridge, Walter B., 36, Baker Street, Reading, Berks., Chemist.
- O.M. Woodcock, R. C., c/o Sanitas Co., Ltd., Locksley Street, Linchouse, London, E., Technical Chemist.
1902. Woodhead, Chas. E., 458, Edge Lane, Droylsden, Manchester, Chemist.
1881. Woodhead, Jas., Inglewood, Slaithwaite, near Huddersfield, Tar Distiller.
1900. Woodrow, John, 84, Harpenden Road, South Wanstead, Essex, Chemist.
1906. Woodward, Horace A., 1268, Amsterdam Avenue, New York City, U.S.A., Chemist.
1904. Woolcott, Geo. H., Lady's Well Brewery, Cork, Ireland, Brewer's Chemist.
1904. Woolcott, Herbert, 44, Zinzan Street, Reading, Brewer's Chemist.
1896. Woolf, Julian, 51, Buckland Crescent, South Hampstead, N.W., Manufacturer.
1906. Woollett, Dr. George H., Science Schools, Sansome Street, Worcester, Principal.
- O.M. Woolley, G. S., Victoria Bridge, Manchester, Pharmaceutical Chemist.
1905. Woore, N. L., P.O. Mount Morgan, Queensland, Australia, Assayer.
1901. Worden, Edw. C., c/o Clark Thread Co., Newark, N.J., U.S.A., Analytical Chemist.
- O.M. Worrall, H., Crimsworth, Whalley Range, Manchester, Dyer.
1903. Worstell, Robt. A., 121, La Salle Street, Chicago, Ill., U.S.A., Paint and Varnish Specialist.
1900. Worthington, Arthur, Lynwood, Green Lane, Bolton, Chemist and Sub-Manager.
1896. Wrampelmeier, T. J., 2253, Piedmont Avenue, Berkeley, Cal., U.S.A., Chemist.
- O.M. Wray, O. J. P., Hazlemere, Coleraine Road, Blackheath, S.E., Technical Chemist.
1904. Wright, Allister M., Box 617, G.P.O., Christchurch, N.Z., Chemist (Christchurch Meat Co.).
1895. Wright, Arthur C., c/o Turner, Morrison, and Co., 6, Lyons Range, Calcutta, India, Chemist.
1908. Wright, C. Harold, Government Laboratory, Port of Spain, Trinidad, B.W.I., Analyst.
1904. Wright, Chas. L., c/o U.S. Geological Survey, 40th and Butler Streets, Pittsburg, Pa., U.S.A., Chemical Engineer.
1905. Wright, Daniel, 287, Maverick Street, East Boston, Mass., U.S.A., Manufacturer of Dyestuffs and Chemicals.
1908. Wright, Gilbert, Chemical Laboratory, University of Sydney, N.S.W., Demonstrator in Chemistry.
1901. Wright, Harold E., c/o Sir B. Samuelson and Co., Ltd., Middlesbrough, Chemist.
1907. Wright, J. G. E., c/o Edison & Swan United Electric Light Co., South Benwell Works, Newcastle-on-Tyne, Technical Chemist.
1907. Wright, John Henry, 22, Norwood Avenue, Shipley, Yorks., Technical Chemist.
1885. Wright, Jos., 19, Arboretum Street, Nottingham, Lace Dresser.
- O.M. Wright, L. T., c/o The Mountain Copper Co., 150, Pine Street, San Francisco, Cal., U.S.A., Chemical Engineer.
1900. Wright, Walter J., 2, St. Mary's Road, Faversham, Kent, Chemist (Cotton Powder Co.).
1890. Wülffing, Dr. Charles, Hönningen a/Rhein, Germany, Technical Chemist.
1907. Würster, Oscar H., The M. Werk Co., 7411, Poplar Street, Cincinnati, Ohio, U.S.A., Soap Works Chemist.
1906. Wuth, Dr. Berthold, Oaklands, Bramhall, Cheshire, Chemist.
1890. Wyall, Dr. Francis, 402, West 23rd Street, New York City, U.S.A., Consulting Chemist.
1905. Wyer, Malcolm G., The Library, State University, Iowa City, Iowa, U.S.A., Librarian.
- O.M. Wyld, Jno., The Avenue, Lidgett Park, Roundhay, Leeds, Chemical Works Manager.
1908. Wyler, Dr. Max, 65, Cecil Street, C. on M., Manchester, Manufacturing Chemist.
1906. Wynne, Prof. W. Palmer, F.R.S., The University, Sheffield, and (Journals) 17, Tiptonville Road, Sheffield, Professor of Chemistry.

Y

1900. Yamaoka, S., 10, Nishikatamachi, Hongo, Tokyo, Japan, Chief Engineer.
1901. Yardley, Frank, c/o Henry Jutson and Sons, Liverpool Street, Birmingham, Chemical Manufacturer.
1899. Yates, Arthur, Lebong Donok, Benkoelen, Sumatra, Netherlands Indies, Metallurgist.
1897. Yates, Wm. H., 119, Hawkshead Street, Southport, Lancashire, Technical Chemist.
1906. Yerkes, Leonard A., c/o Jos. Baneroft and Sons Co., Wilmington, Del., U.S.A., Bleacher and Finisher.
1898. Yetton, Thos., 86, Bow Road, London, E., Consulting Distiller's Chemist.
1894. Yocum, Dr. Jno. H., 359, Halsey Street, Newark, N.J., U.S.A., Chemist.
1886. Yoshida, Prof. H., Imperial University of Kyoto, Kyoto, Japan, Professor of Chemistry.
1900. Yoshitake, E., 18, Tatsukacho, Hongo, Tokyo, Japan, Chemist.
1885. Young, Alfred C., 17, Vicar's Hill, Lewisham, S.E.
1901. Young, Dr. A. H. Innes, 54, Merton Road, Bootle, Student.
1885. Young, Brougham, 2A, Sigdon Road, Dalston, N.E., Analytical Chemist.
1902. Young, Chas. C., c/o Continental Color & Chemical Co., 32, India Street, Boston, Mass., U.S.A., Colourist.
1908. Young, Charles W., 1255, North 26th Street, Philadelphia, Pa., U.S.A., Soap Manufacturer.
1890. Young, Dr. Geo., 79, Harvard Court, Honeybourne Road, West Hampstead, N.W., Chemist.
1904. Young, James, 2A, Dartmouth Road, Brondesbury, N.W., Chemist.
- O.M. Young, Jno., 2, Montague Terrace, Kelvinside, Glasgow, Technical Chemist.
1886. Young, Jno., Claremont House, Beverley Road, Hull, Gas Engineer.
1904. Young, Jno. H., c/o The Cassel Cyanide Co., Ltd., Shuna Street, Maryhill, Glasgow, Technical Chemist.
1898. Young, J. W., 3, Murray Street, Higher Broughton, Manchester, Inspector under Alkali Acts.
1883. Young, Prof. Sydney, F.R.S., University Chemical Laboratory, Trinity College, Dublin, Professor of Chemistry.
- O.M. Young, W. C., Laboratory, 19-20, Aldgate, London, E.C., Gas Examiner and Consulting Chemist.
1898. Young, W. Gathorne, Analyst's Dept., G.N.R., Doncaster, Yorks., Chief Chemist.

Z

1899. Zabriskie, C. B., c/o Pacific Coast Borax Co., 100, William Street, New York City, U.S.A., Manager.
1897. Zacharias, Dr. P. D., Phillellinon Street 22, Athens, Greece, Industrial Chemist.
1897. Zahorski, Dr. Boleslas, Technical Chemist.
1906. Zambra, Edw., 942, Monadnock Building, Chicago, Ill., U.S.A., President (Zambra Co.).

1906. Zdanowicz, Joseph. 9, Knaresborough Place, Earl's Court, S.W., Chemical Engineer (Artificial Silk).
1899. Zilz, Henry. 20-26, Brunswick Place, City Road, London, E.C., Agent (Badische Anilin und Soda Fabrik).
- O.M. Zimmermann, A., 3, Lloyd's Avenue, London, E.C., Chemical Agent.
1905. Zimmermann, Chas., 9 & 10, St. Mary-at-Hill, London, E.C., Chemical Merchant.
1907. Zimmermann, Clarence L., 308, Johnson Court, Madison, Wis., U.S.A., Electro-Chemical Engineer.
1897. Zausser, Dr. Fred. G., Hastings-upon-Hudson, N.Y., U.S.A., Manufacturing Chemist.
1895. Zoeller, E. V., Tarboro, N.C., U.S.A., Cotton-seed Oil Refiner and Pharmacist.
